ATENT AND ACTIVE NEURASTHENIA IN ITS RELATION TO SURGERY *

STUART McGUIRE, M.D.
RICHMOND, VA.

Specialists usually divide functional neurotic disorlers into hysteria, neurasthenia and hypochondria.

Hysteria is a special psychic state often produced in rtain individuals by suggestion, and capable of being elieved by persuasion. It is a condition of nervous nstability, stigmatized by emotional storms, crises, contractures and paralyses, by a craving for sympathy, a [illegible]e for an audience, and a tendency to pose.

Neurasthenia is a fatigue neurosis due in part to malnutrition and in part to functional overexertion, occurring in persons with hereditary or acquired predisposition. It is characterized by exhaustibility of the nervous system, slight exertion causing prostration and bringing on the various distressing symptoms from which the tient suffers.

Hypochondria is a mental disease marked by obses- ons, depressions and morbid fears concerning the health he individual. It is not very common, is easily diag- osticated and is usually incurable.

Hysterical patients give a great deal of trouble before
ion, but do ve[illegible]well after the ordeal is over.
oman who describes her symptoms with hesi-
ivacity, who desires to discuss every detail of her
ation and subsequent treatment, and who is pos-
ssed with exaggerated fears of complications which
ay develop, or of the ultimate result which may follow,
ually, after the operation is over, becomes a model
ient. Her imagination enters on fresh fields; she
comes hopeful and courageous, and begins at once to
an a new life of activity.

Neurasthenic patients usually discuss their cases
lmly and logically; they describe their symptoms sys-
lly and employ technical terms correctly. They
arly every organ in the body. The essen-
ir clinical picture is fatigue, exhaus-
fa for prolonged physical or mental
have rom general weakness, headache,

their disease, and come to the surgeon for what they believe to be a necessary operation.

Hypochondriac patients are the victims of what is often a hopeless psychosis. The individual is possessed with the idea that she has some strange and horrible malady. She soon wears out the patience of her family and friends, and in order to secure a sympathetic listener, and to demonstrate to the community the serious nature of her disease, she goes from surgeon to surgeon, and from hospital to hospital, offering herself as a bloody sacrifice to her curious obsession, and glorying in her martyrdom.

While in theory it is easy to distinguish between hysteria, neurasthenia and hypochondria, in practice it will be found that the symptoms of two or more of them are often present in the same patient at the same time. Thus, one writer says that all hysterical patients are neurasthenic, but that not all neurasthenics are hysterical. Name and classify neuroses as you please, the trail of the serpent is over them all.

In deploring the frequency of neurasthenia, and in criticizing the occurrence of the disease in the hands of practitioners in other departments of medicine, it should be remembered that surgeons are responsible for the development of a large number of these cases. A surgical operation injudiciously performed, or carried out without proper precautions on a susceptible patient, will frequently be the beginning of a neurosis, and terminate in the condition known as traumatic or surgical neurasthenia.

It is my object, first to emphasize the importance of refusing to operate on a neurasthenic patient unless the symptoms can be clearly shown to be due to organic disease, and, second, to emphasize the necessity, if an operation is undertaken on a patient with either latent or developed neurasthenia, of protecting the nervous system from psychical and physical shock, not only by a proper preliminary preparation, but by careful and often prolonged postoperative and posthospital treatment.

A surgeon cannot be expected to be an expert neurologist, but for his own happiness, if not for his patients' welfare, he must study functional neurotic disorders, as well as organic diseases. He must learn to know his limitations, as well as to recognize his abilities, and to estimate the possible injurious effects, as well as the probable beneficial results to be expected from surgical intervention. He must remember that the patient does not come to him primarily to be cut, but to be cured; and that an operation is not a success unless the individual is restored to health, not only physically, but also psychically; not only anatomically, but also symptomatically. In surgery the main question is no longer one of mortality, but one of morbidity. In endeavoring to forecast the final results of an operation, the mental and nervous condition of the patient must be carefully con-

---

at the annual meeting of the Southern
sociation, Hot Springs, Va., Dec. 14-16,

sidered. If neuroses exist, without anatomic disease, an operation will do no good and may result in harm. If neuroses are found coincident with pathologic lesions, an operation may prove of great benefit; but in relieving the physical disease care must be taken to avoid increasing the nervous disorder. If neuroses are present, reflex in character and due to remediable causes, an operation may be undertaken with assurance of complete success. In other words, the surgeon should divide these cases into three classes: the first to be avoided; the second to be undertaken with caution, and the third to be cheerfully given the relief to which they are entitled.

Of the class to be avoided because the neurasthenia has no organic basis, Goodell says:

> The sufferer may be a jilted maiden, a bereaved mother, a grieving widow, or a neglected wife, and all her uterine symptoms—yes, every one of them—may be the outcome of her sorrow, and not of her local lesions. She is suffering from a sore brain and not from a sore womb.

Here an operation will not relieve, but will aggravate, the symptoms.

In the class to be undertaken with caution because the neurasthenia is merely coincident with anatomic disease, it is often a question whether the patient had better endure the evils he has, or fly to those he knows not of. In some cases it may be deemed best to operate, not to cure the neurasthenia, but to relieve the pathologic condition. Great care must be exercised in the management of these cases to avoid increasing the nervous weakness by the very means used to cure the physical discomfort. This is especially true in patients who have been previously the subject of other operations.

Of the class in which the neurasthenia is directly due to anatomic disease, it may be said that if the diagnosis can be made and the cause removed, the patient will be cured. Often the symptoms are obscure and misleading, and much patient investigation will be necessary to reach the proper conclusion. A distinguished modern surgeon cites an instance occurring in his early professional life of a patient long treated, without improvement, for digestive disturbances. The surgeon, who had decided that the man was a neurasthenic, one day found that his patient had acute appendicitis. He operated on him, removing the appendix. Much to his disappointment, the patient, after leaving the hospital, complained as before, and the surgeon was, therefore, confirmed in his opinion that the patient was a neurasthenic. Later, the patient developed jaundice and symptoms of cholecystitis. He was operated on a second time and a number of gallstones removed. Before he left the hospital, however, he began to have his old pains, and then the surgeon said that he knew the patient was a neurasthenic. Without expectations of benefit, a skiagraph was made of the patient's abdomen, and it was found that he had a stone in his right kidney. A third operation was performed, the stone removed, and from that time the patient has been well.

This is not a unique case. All of us have had similar, if not quite such striking, experiences. The story is told to emphasize the fact that even an apparently hopeless neurasthenic should not be condemned without a trial, as some of them may be cured, provided a correct diagnosis is made.

Two separate preliminary examinations should be made of every surgical patient: the first for diagnosis—to determine the condition to be corrected; the second, for prognosis—to determine the safety of the operation and the probability of a complete cure resulting from it. To do this satisfactorily, it will usually be found necessary to secure the aid of several specialists. Few su geons have the time or skill to make the necessary phys cal examination of the heart and lungs, or the laborator investigation of the urine, blood and stomach content to say nothing of the special work which is sometim required of the bacteriologist, ophthalmologist, neurol gist, roentgenologist and other experts. Patients wi not be found to object to frequent and prolonged exam nations, but will be inspired with confidence in the su geon by the realization that nothing is taken for grante and that every effort is being employed to ascertain th nature of their trouble and the best method to effect cure. In fact, the laity are now so educated in medic matters that failure to give a patient a thorough pr liminary examination is a cause for criticism and di trust.

An important exception to this rule, however, is the case of a young unmarried woman who complains pelvic symptoms. She may be of neurotic temperamen and, owing to backache and painful menstruation, h become convinced she has uterine or ovarian diseas when, in fact, she has no local trouble. On the oth hand, she may have cervical stenosis, uterine displac ment, or ovarian cystoma. In such a case a physica examination should be made to ascertain whether th trouble is neurologic or gynecologic. To minimize th psychical shock and to avoid physical pain, the exam nation should be made under a general anesthetic. I the symptoms are due to some defect of the nervous sy tem, the patient should be positively assured that she ha no local lesion, and be referred to a physician for ge eral treatment. If, on the other hand, the symptoms ar due to actual disease of the pelvis, the patient should b given the surgical relief her case demands. Noble ha emphasized the fact that virgins rarely suffer from trau matism and infection of the genital organs, and whe pathologic disease exists they almost invariably deman operative treatment. Repeated examinations, local appl cations, and other manipulations do them little goo and often convert them into chronic nervous invalid The "pelvic woman" of the old author is the "sex neurasthenic" of the modern writer.

The preparation of a patient for operatio both physical and psychic. In the past much atte has been paid to the first, and but little to the secon We now recognize that we have overdone starvatio purgation and disinfection, and have neglected to stud the patient's mental attitude to the operation, in ord to lessen apprehension, if it is unduly present; to inspi confidence, if it is lacking; and to lay the foundation fo a philosophy which will be needed during convalescenc

The first effort should be directed to relieving th patient's dread of going to the hospital. The la being rapidly educated to a just apprecia advantages afforded by such institutions, still regard them as a cross between house. The easiest and most eff this belief is to induce the pati several days before the date fixe the environment of a well-regula ment and fear will soon be rep hope.

The surgeon should see the p ing should be kindly but not patient should be made to real will receive all needful attentio in the day's work. Care should her, not to magnify the importa difficulty and danger incident patient's relatives and friends should, of course, be informed of the facts in the case, but the patient should not be burdened with doubts and fears or made to assume any responsibility for the conduct of the case.

It is, however, important at this time to warn the patient against certain symptoms, complications and sequelæ which may develop after the operation, though they entail no danger and will not affect the final result. For instance, a patient to be operated on for hemorrhoids should be told that possibly she will require catheterization for a day or two; and a patient with fibromyoma of the uterus, that artificial menopause will follow, with symptoms such as usually occur at the "change of life." A word of warning before the operation will be found to be worth more than an hour's explanation afterward, to prevent discouragement from ordinary sequelæ whose significance and importance are not understood.

Finally, the patient's fear of the anesthetic should be relieved by reassurance, reason or ridicule. A badly frightened patient should never be sent to the operating-room. Psychic shock is a greater factor than traumatic shock in the production of surgical neurasthenia.

Some patients are in good nervous and physical condition and require practically nothing but the mechanical correction of a local trouble. Others are as seriously affected nervously as they are physically, and often will be more benefited by a modified form of rest-cure than by the operation itself. Most surgeons recognize this fact, but are often unable to carry out the principles of seclusion, rest, full feeding, bathing, massage and electricity, as taught by Mitchell, because of the present attitude of the public to surgery. Not many years ago an operation was considered, in the words of the marriage ceremony, as something not to be entered into unadvisedly or lightly, but discreetly, soberly, and in the fear of God. To-day it has become to be regarded as a comparatively trivial event, and the principal dread is the surgeon's fee. In the old days it was understood that a patient requiring a serious operation would have to remain two or three months in a hospital. At present, patients enter the hospital one day, are operated on the next, and before they stop vomiting begin to ask when they can go home, and usually are permitted to leave before it is wise for them to do so.

Nearly all surgeons admit the injurious results which frequently follow the premature discharge of a patient from the hospital, and many of them try to evade responsibility by attributing the evil to the unreasonable insistence of the patient to be permitted to return home. The fault, however, is not with the laity, but with the profession. Patients would consent to longer detention in the hospital if they believed it to be necessary. The fault is with a few surgeons who, for various reasons, have entered into a competition to see who can get their patients out most quickly, and have thereby set a precedent which others have followed. Some have been actuated by a desire to save the patient time and money; others by a desire to advertise themselves. The public is prone to estimate the ability of a surgeon by the apparent rapidity of the recovery of his patients, and to make comparisons between different operators on the basis of the length of time they keep their patients in the hospital. This is not surprising, as even some of the profession do not seem to realize fully that, all things being equal, a wound will not heal more quickly for one surgeon than it will for another, and that the number of days a surgeon keeps a patient in bed is not a measure of his surgical dexterity, but of his surgical judgment.

In order to appreciate the dangers to a patient of premature discharge, it is necessary to contrast the conditions of hospital and home life. The change is as decided and the influence as great to the one sex as the other, the man on returning home being confronted by financial obligations and business complications, and the woman by family cares and domestic duties.

What has been said with reference to the short stay of patients in the hospital, and the conditions which frequently exist at home which work adversely to their recovery, makes it plain that those interested in their welfare should consider thoughtfully the situation and endeavor to remove the evil. The remedy obviously consists in the patient's remaining longer under the care of the surgeon, and, on returning home, being placed under the close supervision of the family physician.

A patient should not be detained too long in the hospital, as it is not only a waste of the individual's time and money, but also tends to the creation of invalidism. On the other hand, a patient should not be dismissed too soon, as failure to secure the expected benefit from the operation may lead to discouragement, which finally results in well-established neurasthenia. Convalescence is a question of temperament, and must be psychic as well as physical. People are coming to regard surgeons as mechanics and patients as machines which are to be repaired. They must be taught that the operation is not everything, and that the after-treatment is often of equal importance. They must be made to understand that the operation merely corrects an abnormal condition and puts Nature in a position to effect a cure; that often the first effect of an operation is injurious, and that the beneficial results are experienced only after the system recovers from the shock and readjusts itself to new conditions; that sometimes it takes weeks, months or even years for this to be accomplished. They must be impressed with the fact that, when the wounds have healed, surgical patients are not well, but should remain in the hospital until they have regained to a certain extent their physical strength and nervous equilibrium, and that after returning home, for a time, they should lead a life of prudence and restraint.

The surgeon usually attempts to direct the treatment of patients after they return home by giving them instruction when they leave the hospital, and by subsequently corresponding with them; but the end desired can be more effectually and properly secured by referring the patient back to the family physician. The reason verbal instructions are not satisfactory is that they cannot cover all eventualities, are frequently not understood and are sometimes hasty and perfunctory. The reason subsequent treatment by mail is not satisfactory is that patients usually fail to give important facts, and either exaggerate or underestimate their symptoms; also that the surgeon cannot remember their idiosyncrasies and peculiarities, and, even if he prescribes correctly, his advice lacks the personal element of suggestion which is so essential to make it efficient.

It would be much better if the patient were examined before she left the hospital and told that, while the operation which had been performed had satisfactorily corrected the condition which had given rise to her symptoms she was not yet well and that it would require some months of proper living to restore her to full health and activity; and if she were directed, moreover, on returning home, to place her case in the hands of her family doctor. This would safeguard the patient's future welfare and would overcome to a large extent the growing feeling on the part of the general practitioner that he is not always fairly treated by the surgeon.

Few surgeons are willing to turn patients over to a physician immediately after a serious operation. Complications are often so sudden and dangerous, symptoms so slight and misleading, diagnosis so difficult, and correct treatment so essential, that no one except a man who has had long and constant experience in the management of this special class of cases is competent to have charge of them. When, however, the danger of the operation is over, and the subsequent treatment consists in regulating the various functions of the body, restoring lost flesh and strength and re-establishing nervous and mental equilibrium, the family physician becomes the safer adviser.

With the rapidly increasing amount of surgery being done and the consequent number of convalescent patients under treatment, an educational move ought to be instituted for the study of the many peculiar factors involved. Papers ought to be written and discussions ought to be participated in by both surgeon and family doctor, the various details being taken up and discussed from the different standpoints, until finally there is evolved a consensus of opinion with reference to the many important points in the treatment of these patients. These should include the question of a proper dietary; of the best method of regulating the bowels; of treating bladder irritation; of the number of hours of sleep, and of the necessary periods of rest during the day; of the amount of exercise that is permissible; how soon the sewing-machine may be employed or housework taken up; the question of driving, riding horseback, dancing, swimming and athletic contests; the sort of clothing to be worn; whether corsets are injurious or an abdominal binder necessary; the question of prudence at menstrual periods and the relief of pain often experienced at that time; the treatment of headache, the administration of tonics, nervines and hypnotics; the use of baths, massage and electricity; the protection of wounds; the employment of douches; the use of tampons; the periods at which sexual relations may be resumed—these and a hundred other questions all require consideration in order that they may be settled. When surgeons appreciate the influence of neurasthenia on the result of an operation and the influence of an operation on the production of neurasthenia, when the family physician is educated in the details of posthospital treatment and given legitimate work with proper compensation, then, and not until then, will there be harmony in the profession and the greatest good accomplished to the greatest number of patients.

513 East Grace Street.

Primary Hyperplastic Tuberculosis of Stomach and Duodenum.—A woman of 33, the mother of four children, was admitted to the hospital complaining of loss of flesh, frequent vomiting and a lump in the abdomen. Pain came on a quarter of an hour after taking food. Examination showed a dilated stomach, marked peristalsis and on palpation a hard, movable, elongated tumor below the right costal margin in the position of the pylorus. The duration of the symptoms suggested non-malignancy. At operation later the stomach wall and omentum were covered with miliary tubercles and the glands in the gastro-colic omentum were enlarged. The tumor was smooth on the surface and occupied the whole circumference of the pyloric end of the stomach. The tumor was not removed but a gastrojejunostomy performed. The patient gained 20 pounds but died five months after the operation.—Nash, in *Proc. Royal Soc. Med.*, December, 1909.

MALIGNANT DISEASE OF THE SACRUM SIMULATING SCIATICA

(RADICULAR SCIATICA) *

ALFRED GORDON, M.D.
Neurologist to Mount Sinai, Northwestern General and Douglass Memorial Hospitals
PHILADELPHIA

Localization of pain on the posterior surface of the legs may be indicative of a condition other than the classical sciatica. Although the majority of the classical signs of the latter affection may be present in a given case, nevertheless an error may be committed if a careful examination of the objective sensory disturbances is not made. The mode of distribution of a sensory diminution or exaggeration is an important matter from a diagnostic standpoint. When a peripheral nerve trunk, for example, is affected, the hypoesthesia or anesthesia accompanying the condition is distributed irregularly, in plaques, so to speak, and assumes either a longitudinal or oblique arrangement. When the root of the same nerve trunk is involved the sensory disturbance will be present in a longitudinal form regularly distributed and running parallel with the axis of the limb. We have to deal here with a radicular sensory trouble.

In order to render this subject more comprehensive, it is sufficient to mention the case of Chipault and Demoulin,[1] in which a resection of the ulnar nerve was made for a severe pain confined apparently to the area corresponding to that nerve. As the pain persisted, a second section was made above the first. No relief was obtained. When a thorough and careful examination of the objective sensory disturbances was made, it was found that the seat of the pain did not correspond exactly to the area of distribution of the ulnar nerve, as it was thought on the first superficial examination, but to the area of distribution of the eighth cervical root. Accordingly the latter was resected and recovery immediately followed.

It is, therefore, evident that while subjective disturbances, such as pain, may simulate an affection of a peripheral nerve-trunk, this fact alone is not sufficient for the localization of the lesion. It is the objective investigation that will lead to a proper recognition of the seat of the lesion.

Pain along the course of the sciatic nerve does not necessarily indicate the seat of the lesion in the trunk of the nerve, but it may be also the result of involvement of the plexus from which the sciatic nerve originates, or of the nerve roots. The importance of this knowledge in any given case presenting symptoms of sciatica is evident. Should a surgical condition, for example, in the vicinity of the sacral plexus be overlooked simply because the patient presents the habitual manifestations of sciatica, the error will lead to disastrous results. If, on the other hand, we have to deal with a usual case of neuritis or neuralgia of the sciatic trunk itself, our medical or surgical interference will be directed exclusively to the peripheral trunk of the nerve, but not to its root. The two cases which I am about to report are the best illustration of this contention. The knowledge of involvement of the nerve roots instead of the nerve trunk itself for the lower extremities is comparatively recent.

---

* Read before the Philadelphia County Medical Society, Dec. 8, 1909.

[1] Nouvelle Iconographie de la Salpêtrière, May-June, 1895.

The first observation is that of Lortat-Jacob and Sabaréanu.[2] Since then about a dozen cases have been reported, and this form of sciatica is at present admitted by all writers. The discovery of the affection is due to the extreme care with which cases of sciatica have been studied, particularly from the standpoint of abnormal sensory distribution. The importance of the subject cannot be overestimated, as therapeutic indications are directly dependable on this knowledge.

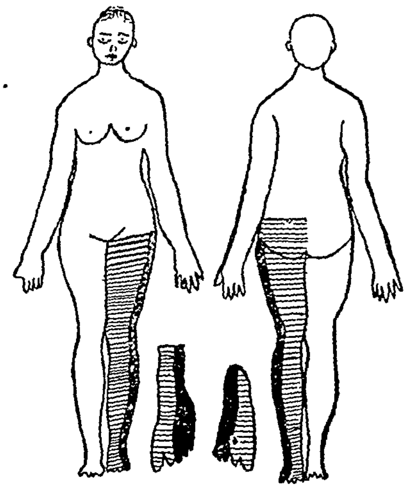
DIFFERENTIAL DIAGNOSIS

When a comparison is drawn between the classical sciatica and a radicular sciatica, we find that, while pain and other subjective sensations, such as burning, coldness, tingling, etc., the tender points of Valleix and Lasègue's sign, are all observed in both forms, the objective sensory distribution is essentially different. On the other hand, the anatomic and experimental studies show that the distribution of a sensory root in the skin does not at all correspond to the mode of distribution of a peripheral nerve-trunk. A nerve-trunk is the result of a combination of an anterior motor root and posterior sensory root. In their intraspinal course the roots are in relation with the vertebræ and dura mater. A lesion within the canal, such as tumor, pachymeningitis, disease of the bone may affect only one of the roots. Should the sensory root alone be involved, the sensory disturbance will follow a special distribution, a root—or radicular distribution. In case of the sciatic nerve we will have, therefore, a radicular sciatica in contradistinction to a neuritis or neuralgia of the nerve-trunk itself.

In the two cases I am reporting, pain along the posterior aspect of the leg was present, which was aggravated by walking. Overextension of the leg caused intense suffering. The tender spots were, however, not complete. In the first case they were observed only at the sciatic notch; in the second case at the notch and in the calf muscles; in both cases the iliac bone was painful. Shortly speaking, the majority of the symptoms of a genuine sciatic neuritis were present here. But what is important is the objective sensory disturbances. They led me to look for the morbid process not in the sciatic nerve-trunk itself, but higher up toward the sacral plexus and the roots themselves. When the involvement of the latter was revealed, the investigation was directed toward the bony canal. Affections of cauda equina and conus medullaris, also of other spinal cord diseases being excluded, the sacral vertebræ were incriminated. A careful and repeated examination led to the discovery of a slight but undoubted enlargement of the sacrum on the affected side. Operative procedures immediately instituted proved the contention to be correct. The affected bone evidently compressed and irritated the sensory branches of the posterior division of the lumbar and sacral nerves distributed over the integument of the gluteal region and sacrum. It also irritated some branches of the sacral plexus and also the common trunk of the sciatic nerve in its passage through the great sacro-sciatic foramen. It was, therefore, a complex condition, and for this reason the complete typical picture of a sciatic neuritis or neuralgia was not present. The predominance of subjective painful phenomena cannot, therefore, be relied on for exact localization.

CASE 1.—Mrs. G., of Brooklyn, had been suffering for two years from pain in the area of distribution of the left sciatic nerve. At first the pain was confined to the level of the posterior superior spine of the ilium, but gradually the entire leg became painful. At the beginning the patient would be relieved by various medications and she would have more or less prolonged intervals of total freedom from pain. At the end of several months the pain became more persistent. Her physician would be obliged frequently to have recourse to morphia, so painful was her condition. Her general health began to suffer. Her sleep and digestion became disturbed and at times she would have delirious attacks. For two years she was considered as a sufferer from sciatic neuritis and treated exclusively by internal medications, particularly by large doses of morphia.

Examination.—At that time the patient came under Dr. John M. Fisher's observation. When I was asked to examine her, the following condition was found: The patient was markedly emaciated and walked with great difficulty across the room. Station was uncertain and especially with closed eyes. Further examination revealed a tenderness of the upper portion of the sciatic nerve and particularly below the posterior superior spine of the ilium. The pain extended upward toward the left iliosacral articulation. In fact, the entire posterior portion of the left iliac region with the adjoining portion of the sacrum was quite painful. In addition to the continuous pain there were also paroxysms of sharp, lancinating, spontaneous pain down along the posterior aspect of the entire left leg. The least motion, and especially extension of the leg, increased the suffering. There were also sensations of numbness, tingling and formication in the legs. As to the objective sensibility, the following phenomena were observed: There is a longitudinal band of complete anesthesia to touch, pain, pressure and temperature along the external border of the left leg (see illustration) beginning from the trochanter down to the foot and occupying the dorsal and plantar surfaces of the foot and the last three toes. The remainder of the leg presents a marked diminution of sensation, but not a complete abolition. The gluteal region is also hypesthetic. No disturbed sensation is observed in the perineal region. The left knee-jerk and the Achilles tendon reflex are markedly exaggerated. The musculature of the leg was very flabby, and although the patient's entire musculature was reduced in size, nevertheless the disturbed nutrition was more evident in the left leg than in the right. The affected leg is decidedly colder than the right. The sphincters of the patient were intact, as there was no disturbance of their function.



Figures showing areas of complete and partial anesthesia; solid black portions showing anesthesia and shaded portions showing hypesthesia.

Diagnosis.—The symptoms thus described presented apparently a clear picture of sciatica, but the character of the pain and its extension toward the upper portion of the iliac bone and the corresponding portion of the sacrum, and, finally, the objective sensory disturbance mentioned above, altered greatly the symptom group of the classical sciatic neuritis and suggested a possibility of a larger involvement than merely that of the sciatic nerve trunk. When the patient was placed flat on her abdomen there was at first glance nothing abnormal noticeable, but a close inspection and palpation revealed a slight but undoubted inequality of the right and left sides of the lower portion of the sacrum. The left side was somewhat larger and thicker and pressure on it caused pain. A control examination was made through the rectum and here the above difference could be felt still more readily. It was therefore evident to me that the enlarged and thickened left portion of the sacrum exercised pressure on the posterior division of the lumbar and sacral nerves and the left sacral plexus. The latter is formed by the lumbosacral cord, the anterior divisions of the three upper sacral nerves and part of the fourth. It is triangular in form, its base corresponding with the exit of the nerves through the anterior sacral foramina, its apex with the great sacrosciatic foramen. The sacral foramina are situated laterally at the end of transverse ridges seen between the separate pieces of the sacrum.

---

[2] Presse Médicale, 1904, No. 80.

The posterior primary divisions of the lumbar and sacral nerves are distributed over the integument of the gluteal region. The branches of the sacral plexus supply the gluteal muscles, the pyriformis, obturator internus and quadratus femoris. Their function is to rotate the thigh outward; the gluteus maximus extends the hip-joint, the gluetus medius and minimus are abductors also, move the thigh forward and rotate it inward and backward. All these movements were somewhat reduced in my patient. Whether the weakness of the muscles was the direct cause of the slight impotence of the limb, or else the pain interfered with motion, was difficult to determine. As to the cutaneous branches of the sacral plexus, only some of them were involved. The small sciatic was only partly affected, as the long pudendal nerve was intact. The sensibility of the perineum and of the labia majora was normal. The anesthesia of the limb corresponds to the first and second sacral nerve roots. The hypesthesia corresponds to lumbar nerve roots.

A careful analysis of the sensory distribution shows that the following nerve roots are affected: First, second, third and fourth lumbar and second sacral.

Operation.—In view of the findings in the bony tissue, which were sufficient to account for the symptoms referable to several nerve roots, operative procedures were indicated. Dr. E. G. Montgomery, who performed the operation, has kindly supplied me with the following report: "Through an excision extending across the lower end of the sacrum and coccyx from the left to the right side, the coccyx was exposed and removed, then the tissues pushed off from the inner surface of the sacrum and with the rongeur the lower portion of the bone was removed, when we opened into a pulpy mass which consisted largely of disintegrated bone. This was beneath and did not involve the periosteum covering the anterior surface of the sacrum. This tissue was worked away with a rongeur and curette until about one and one-half to two inches of the lower and middle portion of the sacrum was removed. The cavity was then packed with iodoform gauze and the greater portion of the external wound closed."

Tissue Examination.—The removed tissue was sent to the patient's former physician in Brooklyn and Dr. A. S. Wolf of the laboratory of pathology, bacteriology and chemistry sent us the following report: "The tissue is composed principally of glandular tissue lined with columnar epithelium. The acini are well enclosed by a connective tissue reticulum with the tendency of breaking down or extension. Epithelial cells and connective tissue cells show no infiltration and no degeneration. The specimen throughout gives no tubercular picture. The specimen appears to be cylindrical epithelioma originating from misplaced embryonic tissue."

Subsequent History.—The operation was followed by gradual improvement in the general condition and considerable relief from pain. The healing of the wound was very slow, but the pain became progressively less. At the end of a month there was very little complaint of pain. The former tender spots along the sciatic nerve became less sensitive. The patient was then taken back to her home in Brooklyn and placed in charge of her family physician. His first reports were excellent. The patient was practically free from pain and she gained in weight. Unfortunately the improvement was only temporary. Gradually the pain returned and even with greater severity in the region of sacroiliac articulation. Large doses of morphia had to be used. The patient finally died in a state of complete exhaustion. No autopsy was obtained.

Case 2.—Mrs. H. S., aged 35, has been suffering for eighteen months from pain in the areas of distribution of both sciatic nerves and in the sacral region.

Examination.—A careful examination revealed some symptoms of double sciatica, viz., pain in walking, pain on extension of both legs, tender spots between the ischium and the trochanter and in the middle of the calf muscles. She also had spontaneous pain along the posterior aspects of the legs, more on the right than on the left side, but the pain in the sacrum was of unusual severity. Both gluteal regions were highly hyperesthetic and the patient had difficulty in walking. The knee-jerks and the Achilles tendon reflex were markedly exaggerated. There was no other abnormal reflex. The sphincters were intact. The muscles of the lower limbs were much wasted and flabby, but there was also a general wasting of the musculature of the entire body.

Diagnosis.—With a singular similarity the objective sensory disturbances were those of the first case, excepting a somewhat larger band of anesthesia extending more anteriorly than posteriorly and more in the right limb than in the left. The hypesthesia covered the remainder of both limbs except the gluteal regions, which, as said above, were hyperesthetic. The difference between the two cases was only in the extent of the involvement. In the first case the affection was unilateral, in the second bilateral. Here again the symptoms pointed to some irritative process going on not in the trunk of the sciatic nerve, but above in the lumbar and sacral roots. To avoid repetition one can refer to the history of the first case as to the details of individual nerves involved. The character of the pain in the sacral region was identical with that of our first patient.

Operation.—The patient was considered for eighteen months a sufferer from sciatica and treated exclusively with internal medications. A pelvic examination made by Dr. J. M. Fisher excluded any pressure from that source. I then made the diagnosis of a disease of the sacrum and perhaps of lumbar vertebræ with secondary involvement of lumbar and sacral roots probably through irritation. I then learned that the patient had several years ago one breast removed for some malignant growth. Her general appearance was cachectic and therefore suggested a malignancy of the bony tissue of the sacrum. As in the first case, I advised an operation, which was performed by Dr. Fisher.

Tissue Examination.—The specimen removed by him was examined in the pathologic laboratory of the Jefferson Hospital, and the report is as follows: "The triangular piece of tissue measures each side 4 cm. and the base 3 cm. The tissue is hard and bone-like and on the outer aspect is a small amount of bright red soft tissue. The periosteum is intact. At the base the bone is somewhat lacerated. The medullary portion contains a small amount of rather firm, dark red tissue. The soft tissue is made up of rather loosely woven fibrosa which is wavy, intensely stained and contains numerous cells, some spindle-shaped, others round. They stain fairly well. At some points the sections are cellular, the elements being large and ovoidal. The nuclei are ovoidal, vesicular, and contain very little chromatin. The protoplasm is rather abundant, granular and transparent. Throughout the sections are small areas containing large cells which are ovoidal, vary from 15 to 25 microns in diameter, and contain more than one nucleus. The protoplasm is rather dense and hyalin. In some parts of the section is a basic staining substance containing granular bodies. The bone presents similar changes. Diagnosis: Giant-cell sarcoma."

Subsequent History.—The operation brought some relief from pain. Patient began to recuperate and progressed fairly well, when a recurrence of pain took place. This time the pain was concentrated in the sacral region and from there gradually ascended along the spine. Her sufferings became intense. The general cachectic condition became more and more pronounced. At the end of two months the patient expired. No autopsy was obtained.

IMPORTANT FEATURES

The two cases present very important features.

1. From an etiologic standpoint the involvement of the sacrum was the direct cause of the sciatic symptom group.

2. The predominance at first of the sciatic pain over the sacral pain, but later the reversed condition.

3. The error to which the latter circumstance led, viz.: the affection was considered for an ordinary case of sciatica and therefore the sacral pain was overlooked and consequently operation delayed with disastrous results.

4. Not one of the cases presents a complete picture of the classical sciatica. While spontaneous pain was present along the limb, some of the tender spots could be brought out and overextension of the leg caused great discomfort; nevertheless, the anesthesia, the hypesthesia in the limb, and in the gluteal region all pointed to a lesion above the sciatic nerve. An exact study of the sensory disturbance led to the localization of the affection in the nerve roots of the spinal cord. The latter, in its turn, directed attention to the cause of the root irritation and a material factor was discovered in the vertebræ. We had, therefore, to deal with a root condition simulating sciatica, viz.: a radicular sciatica.

5. The two cases are instructive from this standpoint, that they show the necessity of making thorough and very careful investigations of patients who come under observation even with the most common pathologic conditions.

In connection with the latter remark I wish to mention another case seen in consultation with Dr. Wayland in Crozet, Va.

A middle-aged woman suffered severe pains in the legs, particularly in the areas of distribution of the sciatic nerves. Prior to Dr. Wayland's treatment she was considered to be a sufferer from double sciatica. Accordingly, the two nerves were stretched and other surgical manipulations performed on the nerves. When Dr. Wayland first saw her, he suspected more damage than only in the sciatic nerves. When I saw the patient, she presented all the symptoms of a spinal cord tumor, viz., very severe pain in the mid-thoracic region, radiating around the waist, total paralysis with loss of all the reflexes, total loss of sensations below the waist line, incontinence of the bladder and rectum. The outlook was most grave, as the disease had been of two years' standing. The patient died in two months.

CONCLUSIONS

The three cases related belong to the domain of surgery. No doubt, when taken in the proper time, surgery probably could have prolonged life.

The conclusion that forces itself on us is the fact that sciatica which is persistent and which is accompanied also by pain in regions other than the great ischiosacral notch, is to be looked on with suspicion, especially when the pain is spontaneous and not exclusively on motion. Such cases should be carefully analyzed, not only as to the objective sensory and motor disturbances, but also as to the condition of the pelvic organs and the bony structure with which the nerve roots are in close touch.

FAT: A PHYSIOLOGIC APPRECIATION

GEORGE M. NILES, M.D.
Lecturer on Physiology, Atlanta School of Medicine; Gastro-enterologist to the Tabernacle Infirmary
ATLANTA, GA.

The rôle of fat in the human organism may be considered as material, esthetic, and psychic. The first may be physiologic, pathologic, or economic in its aspect; the second may mark the difference between the rounded anatomic contour, displaying at its best the human form divine, the beauteous Venus, the plump Cupid, and the haggard ugliness shown in emaciation, or in the stage of the "shrunk shank" and "the lean and slippered pantaloon."

The psychic manifests its influence over the temperament and disposition from earliest infancy throughout life, and I shall endeavor to prove that in this particular the rôle of fat has not received sufficient consideration.

Protein, that prolific source of animal energy and vigor, needs no advocate to plead its rights, for by its very nature the *protein content* will always command a liberal share of attention. Fat, however, is often unappreciated, often misunderstood, and more often unjustly blamed for sins or delinquencies of other food products, so that a general survey of this subject, possibly more discursive than scientific, commended itself to me as being of probable interest.

From 15 to 20 per cent. of each healthy body is composed of fat, though only about one-fourth of an ounce is contained in the blood. The amount of fat within normal limits varies widely, often being influenced by heredity, age and personal habit more than the quantity of food taken. Where there is a tendency to take on fat, it readily accumulates under either a slight increase of the daily diet or a decrease of regular exercise. The storage of fat is also favored by sleep, as it has been shown during periods of somnolent inactivity fatty deposits most readily find snug and convenient resting places.

The chief sources of fat are the starches and sugars, though certain fats are directly utilized. Emulsified fat is split to a considerable extent by the stomach steapsin, an enzyme which acts efficiently only when concentrated. It might be well to mention that pepsin has not been shown to possess any fat-splitting action.

As the fat is carried past the pyloric outlet, it is immediately acted on by the pancreatic juice, and, until recently, it was generally assumed that it was partly broken down by the pancreatic secretion into fatty acids and glycerin; that the former united with the alkalies of the intestines to form soaps, and that the soaps brought about an emulsification of the fat. On account of its alkalies, bile was said to play an important part. Unlike other nutritive substances, fat would then pass from the intestinal canal into the mucous membrane, not in solution, but as an emulsion. The weight of present opinion, however, would lead us to believe that fats are completely decomposed in the intestine, and that the fatty acids formed are absorbed either as soaps or in a solution brought about by the bile.

As a source of energy for the development of heat, fat may be described as quickly available, but not so lasting. Experiments of both Rubner and Atwater have demonstrated that food-stuffs generate the same quantity of heat when burned within the body as when burned outside the body, and that, while one gram of protein or one gram of carbohydrate will each generate approximately four calories, one gram of fat is good for over nine calories. The conclusion, therefore, is obvious that by its concentrated fuel power fat preserves other tissues, especially the albuminous, from destruction by oxidation and is valuable as a reserve force, instantly available when any vital emergency requiring it arises.

Another material function of fat is that of "protein sparer," for, though its tissue-building properties are limited and incidental, by its presence the protein is permitted better to perform its manifold tasks. We might with propriety, in this connection, liken fat to the housewife, who, though not apparently earning anything, by her care and industry conserves the fruits of her husband's labor, enabling him not only to support the domestic establishment, but also to lay aside a surplus. Should an emergency arise whereby the head of the house becomes incapacitated, this housewife could at once become an active earning factor, augmenting the depleted income and possibly averting economic disaster.

As a storage of energy ready to be drawn on as needed fat is of great importance. In starvation about 90 per cent. of the body fat is consumed before death, so we can easily see how a generous physiologic supply laid up for a time of stress will aid in a battle against wasting disease or defective assimilation. Fat also, though generally burned rapidly, is used very slowly when there is little muscular activity, as shown by animals in hibernation.

The last material use of fat is to serve as a covering and protection to the body against both injury and cold; in other words, to cushion the frame. Fat babies can bear without hurt falls that would seriously injure thin ones; fat people can stand with impunity many hard knocks that would completely demoralize attenuated individuals, while a good blanket of subcutaneous adipose tissue will answer every purpose that could be expected of woolen underwear or heavy clothing.

From an esthetic standpoint, the physiologic and orderly distribution of fat in the connective tissue marks the contrast between physical beauty and gaunt ugliness. Painters, novelists and dramatists have been quick to note the difference, and in their delineations of physical charm emaciation never finds a place. On the contrary, the villain as most often described is a cadaverous-looking wretch, with peaked nose, lantern jaw and skinny limbs. Should fat be present by any chance, it is pictured in pathologic and disgusting quantities. In fact, history, literature and art are full of examples demonstrating that in the entire animal kingdom there can be no comeliness in the absence of fat.

That fat will accumulate in unused portions of the body while it disappears in regions of local activity has been utilized by directors of physical culture as well as "beauty doctors" the world over. Various forms of exercise, both systematic and scientific, have been devised, besides numerous appliances, all aiming to increase or decrease fatty deposits in different parts of the human anatomy. By exercise alone some forms of obesity may be corrected, while abdomens of aldermanic proportions can readily be abated. There are also ingenious methods by which too prominent angles, as well as unsightly hollows, may be cushioned or filled with fat, so that to the earnest seeker of physical attractiveness, in the absence of serious wasting disease, there is nearly always "balm in Gilead."

In considering the psychic rôle of fat, we should specially bear in mind its reserve function in relation to active vital processes. In the proper conduct of the human mechanism there is just the right amount of labor for each organ to perform, but generous Nature allows sufficient latitude within physiologic limits to meet ordinary emergencies. Extraordinary conditions unless fortified against may result disastrously, and a liberal deposition of fat is one of Nature's wise precautions.

It has been commonly known from the earliest antiquity that fat people are more contented, more optimistic, than lean ones and that their viewpoint of life in general is largely governed by this prosaic attribute. Now I might compare the supply of fat to the ample bank account of a busy and provident man. That he possesses this surplus does not prevent him from diligently following his usual avocation, but the knowledge of its presence and that it can be instantly obtained lends a mental satisfaction that would be absent were he living right up to his daily income.

I believe, therefore, that my reasoning is correct when I assert that a physiologic reserve of fat by its very presence exerts a quieting and reassuring influence on the vital forces most concerned in constructive metabolism; and, if I may apply a scriptural quotation, this reserve, in language intelligible to those forces, says: "Thou hast much goods laid up for many years; take thine ease, eat, drink and be merry."

On the other hand, when the department of constructive housekeeping in the body is furnished barely enough to ward off retrograde metamorphosis; when obscure nooks and recesses have to be frequently ransacked for their scanty stores of fat in order to keep up normal oxidation; when nutrition is at par only a part of the time, while the protein content has to work overtime in order to manufacture sufficient energy and heat, then is felt the vibrations of a tiny voice of unrest and bodily discontent, which discontent and unrest sooner or later react on the disposition, developing into that pessimism and temperamental dissatisfaction so often present in lean people.

The limits of this paper will not permit a discussion of the dietetics of fat, a comparison of its vegetable and animal forms, or its adaptability to different conditions, as age, occupation or environment. Let this be considered rather a physiologic appreciation of that food element, which, lacking the strenuous qualities of protein, the versatility of the carbohydrates, or the leavening functions of the inorganic salts, fulfills a manifold mission of its own, lending to the body warmth and security, to the mind peace and good cheer.

409 Candler Building.

The Public and the Medical Profession.—The public is a self-constituted critic, prejudiced against the profession and clamoring for demonstrated achievement, but it is also like a great child needing to be led into the way of cleanliness, godliness and health. With the spirit of to-day the public is ready for education, and we owe it to ourselves to go more than half way in the effort to instruct it. When that day comes in Utopia, when the state will care for all its sick, educate, train and keep its staff of physicians, lay restrictions of community obligation to health on all citizens, provide for the prevention of disease by instruction in schools and in the communities of peoples, as well as the means to safeguard the individual, then our labors will have ceased, but until such a dream is realized, we must continue to knock at the door of the Empire of Hygeia, begging the spiritual and economic aid of all to further our cause, always humanitarian in its purpose and conservative in its results.—Isadore Dyer, in *Southern Medical Journal.*

VACCINATION AND ITS RELATION TO ANIMAL EXPERIMENTATION *

JAY FRANK SCHAMBERG, M.D.
PHILADELPHIA

(Concluded from page 951)

THE RESULTS OF VACCINATION REQUIREMENTS IN VARIOUS COUNTRIES

The Imperial Board of Health of the German Empire gives the frequency of smallpox in various European countries between 1893 and 1897, inclusive, a period of five years.

TABLE 11.—THE FREQUENCY OF SMALLPOX IN EUROPEAN STATES BETWEEN 1893-1897 INCLUSIVE (FIVE YEARS)

Country.	Population.	Average Yearly Mortality in Every Million Population.	Actual Number Smallpox Deaths.	Year.
Germany	52,042,282	1.1	287	5
Denmark	793,356	0.5	2	5
Sweden	4,894,790	2.1	41	4
Norway	2,045,900	0.6	5	4
England and Wales	30,389,524	20.2	3,066	5
Scotland	4,155,886	12.3	256	5
Ireland	4,580,555	9.9	226	5
Switzerland	3,032,901	5.1	78	5
Netherlands	4,797,249	38.7	929	5
Belgium	6,419,498	99.9	3,208	5
French States	8,253,079	90.2	3,721	5
Russian Empire, including Asiatic Russia	118,950,400	463.2	275,502	5
Austria	23,000,000	99.1	11,799	5
Italy	31,007,422	72.7	11,278	5
Spain	10,596,649	563.4	23,881	4
Hungary	18,234,916	134.3	12,241	5

The countries which during this period have the most stringent vaccination laws suffer the least smallpox, namely, Germany, Denmark. Sweden and Norway.

In well-vaccinated Germany, but one person a year in every million of population died of smallpox.

In England and Wales, where vaccination is generally but not universally practiced, 20 persons per million died of smallpox each year.

Thorough vaccination has practically banished smallpox from the huge German army. Kübler[12] says:

> On only two occasions since the year 1874 (in 1884-85 and in 1889) has a death from smallpox occurred in the Prussian Army, and the first of these was in the person of a reservist who seven years before had been twice unsuccessfully vaccinated.

VACCINATION IN THE PHILIPPINE ISLANDS

Of particular interest is the recent achievement of the United States sanitary authorities in stamping out smallpox in the Philippine Islands. In 1905 and 1906 the enormous number of 3,094,635 vaccinations were performed. Dr. Victor G. Heiser, Director of Health of the Islands, in the Report of the Bureau of Health (June 30, 1907), states:

> In the provinces of Cavite, Batangas, Cebu, Bataan, La Union, Rizal and La Laguna, where heretofore there have been more than 6,000 deaths annually from smallpox, it is satisfactory to report, since the completion of vaccination in the aforesaid provinces more than a year ago, not a single death from smallpox has been reported.

IMMUNITY OF VACCINATED PHYSICIANS, NURSES AND ATTENDANTS IN SMALLPOX HOSPITALS

If it can be demonstrated that physicians, nurses and attendants in smallpox hospitals can be perfectly protected by vaccination, then this must be regarded as a crucial test of its protective influence; for if these persons, living in the same atmosphere with scores or hundreds of smallpox patients, breathing their very exhalations, are enabled to escape the infection, it certainly should be possible for others much less exposed to acquire similar immunity.

Experience shows that physicians, nurses and attendants, if recently successfully vaccinated or revaccinated, may live in smallpox hospitals in perfect safety. Dr. Marson, physician to the Smallpox Hospital of London for many years, giving evidence in 1871, stated that during the preceding thirty-five years no nurse or servant at the hospital had been attacked with smallpox. Dr. Marson took the precaution of revaccinating all attendants before permitting them to go on duty. Dr. Collie, whose experience is also large, says: "During the epidemic of 1871, out of one hundred smallpox attendants at Homerton (England) all but two were revaccinated, and these two took smallpox." Dr. T. F. Ricketts, medical superintendent of the smallpox hospital ships on the Thames, states that out of 1,201 persons in attendance on board the smallpox ships, only six contracted the disease, all of them recovering. None of these six persons had been successfully revaccinated before going on duty. According to Dr. Hill, of Birmingham (England), during the epidemic of 1893, over one hundred persons were employed at the City Smallpox Hospital, all of whom had been recently revaccinated; not one of them contracted smallpox.

Dr. William M. Welch, of Philadelphia, states that in the Municipal Hospital of Philadelphia during a period of thirty-four years, in which time almost 10,000 cases of smallpox were treated, there was no instance of a physician, nurse or attendant who had been successfully vaccinated or revaccinated prior to going on duty contracting the disease.

PHYSICIANS AND NURSES NOT PROTECTED AGAINST OTHER CONTAGIOUS DISEASES

Physicians and nurses do not exhibit immunity toward other contagious diseases as they do with respect to smallpox. According to Ernest Hart, in 1893, of 2,484 persons employed in the Metropolitan Fever Hospital of London, 130 became infected and 2 died. Four assistant medical officers, 10 nurses, 43 assistant nurses, and 16 maid servants were attacked by scarlet fever. Two assistant medical officers, 6 nurses, and 15 assistant nurses contracted diphtheria.

While the deaths from smallpox of physicians (who constitute a class particularly well vaccinated) are but 13 per million, in England, the deaths of the general population are 73 per million. In scarlet fever, on the other hand, against which physicians have no special protection, the figures are reversed: 59 medical men per million die of scarlet fever, as against 16 per million of the general population.

ALLEGED DANGERS OF VACCINATION

Every human act is accompanied by some measure of danger. When one rides in an elevator, in a railroad car, or even promenades on the sidewalk, he takes a certain definite risk which can be mathematically calculated. While in the aggregate the number of accidents and deaths from each of these causes may be considerable, yet the individual risk is so small that it may be disregarded. It is the same with reference to vaccination.

Inasmuch as vaccination necessitates the production of an abrasion or wound, it is naturally liable to infections to which wounds from other causes are subject. Such a four calories, one gram of fat is good for over nine calories. The conclusion, therefore, is obvious that by its concentrated fuel power fat preserves other tissues, especially the albuminous, from destruction by oxidation and is valuable as a reserve force, instantly available when any vital emergency requiring it arises.

---

* This article is here considerably abbreviated. The complete article is one of a series of pamphlets issued by the Council on Defense of Medical Research of the American Medical Association for circulation among the public. Twelve of these pamphlets are now ready, taking up the relations of animal experimentation to ethics, diagnosis, cancer, vaccination, the live stock industry, tuberculosis, typhoid, dysentery, rabies, surgery, internal secretions; protozoan tropical diseases, etc.

[12] Kübler: Geschichte der Pocken und der Impfung, 1901, p. 383.

Another material function of fat is that of "protein sparer," for, though its tissue-building properties are limited and incidental, by its presence the protein is permitted better to perform its manifold tasks. We might with propriety, in this connection, liken fat to the housewife, who, though not apparently earning anything, by her care and industry conserves the fruits of her husband's labor, enabling him not only to support the domestic establishment, but also to lay aside a surplus. Should an emergency arise whereby the head of the house becomes incapacitated, this housewife could at once become an active earning factor, augmenting the depleted income and possibly averting economic disaster.

As a storage of energy ready to be drawn on as needed fat is of great importance. In starvation about 90 per cent. of the body fat is consumed before death, so we can easily see how a generous physiologic supply laid up for a time of stress will aid in a battle against wasting disease or defective assimilation. Fat also, though generally burned rapidly, is used very slowly when there is little muscular activity, as shown by animals in hibernation.

The last material use of fat is to serve as a covering and protection to the body against both injury and cold; in other words, to cushion the frame. Fat babies can bear without hurt falls that would seriously injure thin ones; fat people can stand with impunity many hard knocks that would completely demoralize attenuated individuals, while a good blanket of subcutaneous adipose tissue will answer every purpose that could be xpected of woolen underwear or heavy clothing.

From an esthetic standpoint, the physiologic and orderly distribution of fat in the connective tissue marks the contrast between physical beauty and gaunt ugliness. Painters, novelists and dramatists have been quick to note the difference, and in their delineations of physical charm emaciation never finds a place. On the contrary, the villain as most often described is a cadaverous-looking wretch, with peaked nose, lantern jaw and skinny limbs. Should fat be present by any chance, it is pictured in pathologic and disgusting quantities. In fact, history, literature and art are full of examples demonstrating that in the entire animal kingdom there can be no comeliness in the absence of fat.

Germany	52,042,282	1.1	287	5
Denmark	793,356	0.5	2	5
Sweden	4,894,790	2.1	41	4
Norway	2,045,900	0.6	5	4
England and Wales	30,389,524	20.2	3,066	5
Scotland	4,155,886	12.3	256	5
Ireland	4,580,555	9.9	226	5
Switzerland	3,032,901	5.1	78	5
Netherlands	4,797,249	38.7	929	5
Belgium	6,419,498	99.9	3,208	5
French States	8,253,079	90.2	3,721	5
Russian Empire, including Asiatic Russia	118,950,400	463.2	275,502	5
Austria	23,000,000	99.1	11,799	5
Italy	31,007,422	72.7	11,278	5
Spain	10,596,649	563.4	23,881	4
Hungary	18,234,916	134.3	12,241	5

The countries which during this period have the most stringent vaccination laws suffer the least smallpox, namely, Germany, Denmark, Sweden and Norway.

In well-vaccinated Germany, but one person a year in every million of population died of smallpox.

In England and Wales, where vaccination is generally but not universally practiced, 20 persons per million died of smallpox each year.

Thorough vaccination has practically banished smallpox from the huge German army. Kübler[12] says:

> On only two occasions since the year 1874 (in 1884-85 and in 1889) has a death from smallpox occurred in the Prussian Army, and the first of these was in the person of a reservist who seven years before had been twice unsuccessfully vaccinated.

VACCINATION IN THE PHILIPPINE ISLANDS

Of particular interest is the recent achievement of the United States sanitary authorities in *stamping out* smallpox in the Philippine Islands. In 1905 and 1906 the enormous number of 3,094,635 vaccinations were performed. Dr. Victor G. Heiser, Director of Health of the Islands, in the Report of the Bureau of Health (June 30, 1907), states:

> In the provinces of Cavite, Batangas, Cebu, Bataan, La Union, Rizal and La Laguna, where heretofore there have been more than 6,000 deaths annually from smallpox, it is satisfactory to report, since the completion of vaccination in the aforesaid provinces more than a year ago, not a single death from smallpox has been reported.

IMMUNITY OF VACCINATED PHYSICIANS, NURSES AND ATTENDANTS IN SMALLPOX HOSPITALS

If it can be demonstrated that physicians, nurses and attendants in smallpox hospitals can be perfectly protected by vaccination, then this must be regarded as a crucial test of its protective influence; for if these persons, living in the same atmosphere with scores or hundreds of smallpox patients, breathing their very exhalations, are enabled to escape the infection, it certainly should be possible for others much less exposed to acquire similar immunity.

Experience shows that physicians, nurses and attendants, if recently successfully vaccinated or revaccinated, may live in smallpox hospitals in perfect safety. Dr. Marson, physician to the Smallpox Hospital of London for many years, giving evidence in 1871, stated that during the preceding thirty-five years no nurse or servant at the hospital had been attacked with smallpox. Dr. Marson took the precaution of revaccinating all attendants before permitting them to go on duty. Dr. Collie, whose experience is also large, says: "During the epidemic of 1871, out of one hundred smallpox attendants at Homerton (England) all but two were revaccinated, and these two took smallpox." Dr. T. F. Ricketts, medical superintendent of the smallpox hospital ships on the Thames, states that out of 1,201 persons in attendance on board the smallpox ships, only six contracted the disease, all of them recovering. None of these six persons had been successfully revaccinated before going on duty. According to Dr. Hill, of Birmingham (England), during the epidemic of 1893, over one hundred persons were employed at the City Smallpox Hospital, all of whom had been recently revaccinated; not one of them contracted smallpox.

Dr. William M. Welch, of Philadelphia, states that in the Municipal Hospital of Philadelphia during a period of thirty-four years, in which time almost 10,000 cases of smallpox were treated, there was no instance of a physician, nurse or attendant who had been successfully vaccinated or revaccinated prior to going on duty contracting the disease.

PHYSICIANS AND NURSES NOT PROTECTED AGAINST OTHER CONTAGIOUS DISEASES

Physicians and nurses do not exhibit immunity toward other contagious diseases as they do with respect to smallpox. According to Ernest Hart, in 1893, of 2,484 persons employed in the Metropolitan Fever Hospital of London, 130 became infected and 2 died. Four assistant medical officers, 10 nurses, 43 assistant nurses, and 16 maid servants were attacked by scarlet fever. T[illegible]o assistant medical officers, 6 nurses, and 15 assis[illegible]nt nurses contracted diphtheria.

While the deaths from smallpox of physician[illegible] (who constitute a class particularly well vaccinated) [illegible]e but 13 per million, in England, the deaths of the [illegible]neral population are 73 per million. In scarlet fever, o[illegible] the *other hand*, against which physicians have no
protection, the figures are reversed: 59 me
million die of scarlet fever, as against
the general population.

* This article is here considerably abbreviated. The complete article is one of a series of pamphlets issued by the Council on Defense of Medical Research of the American Medical Association for circulation among the public. Twelve of these pamphlets are now ready, taking up the relations of animal *experimentation* to ethics, diagnosis, cancer, vaccination, the live stock industry, tuberculosis, typhoid, dysentery, rabies, surgery, internal secretions; protozoan tropical diseases, etc.

12. Kübler: Geschichte der Pocken und der Impfung, 1901, p. 383.

lated within recent decades by the proof that a most intimate relationship exists between vaccinia and smallpox. Indeed, it has been demonstrated that the intensely contagious virus of smallpox can be transformed into the benign vaccine virus, the latter having the property of protecting against smallpox when inoculated into the human subject. Moreover, the affection produced by the vaccine virus, unlike that produced in the last century by inoculation of smallpox virus, results in a disorder which is *non-contagious*. This proof of the relation between vaccinia and smallpox has been brought about through animal experimentation carried on through many years by scientific men in France, Switzerland, Germany and Great Britain.

It has taken almost a century of experimentation to prove the truth of the statement made by Jenner in his first publication, that smallpox and cowpox were modifications of the same disease. What a tribute to the intuitive discernment of this great man!

THE VALUE OF THE ABOVE EXPERIMENTS

The demonstration of the proof that vaccine virus may be developed from smallpox virus is of the greatest importance to mankind. Cases of spontaneous cowpox, from which most strains of vaccine lymph were originally derived, are excessively rare. In Württemberg, in 1825, a reward was offered for the discovery of cases of spontaneous cowpox. There is a reassuring sense of security, therefore, in the knowledge that in a case of the

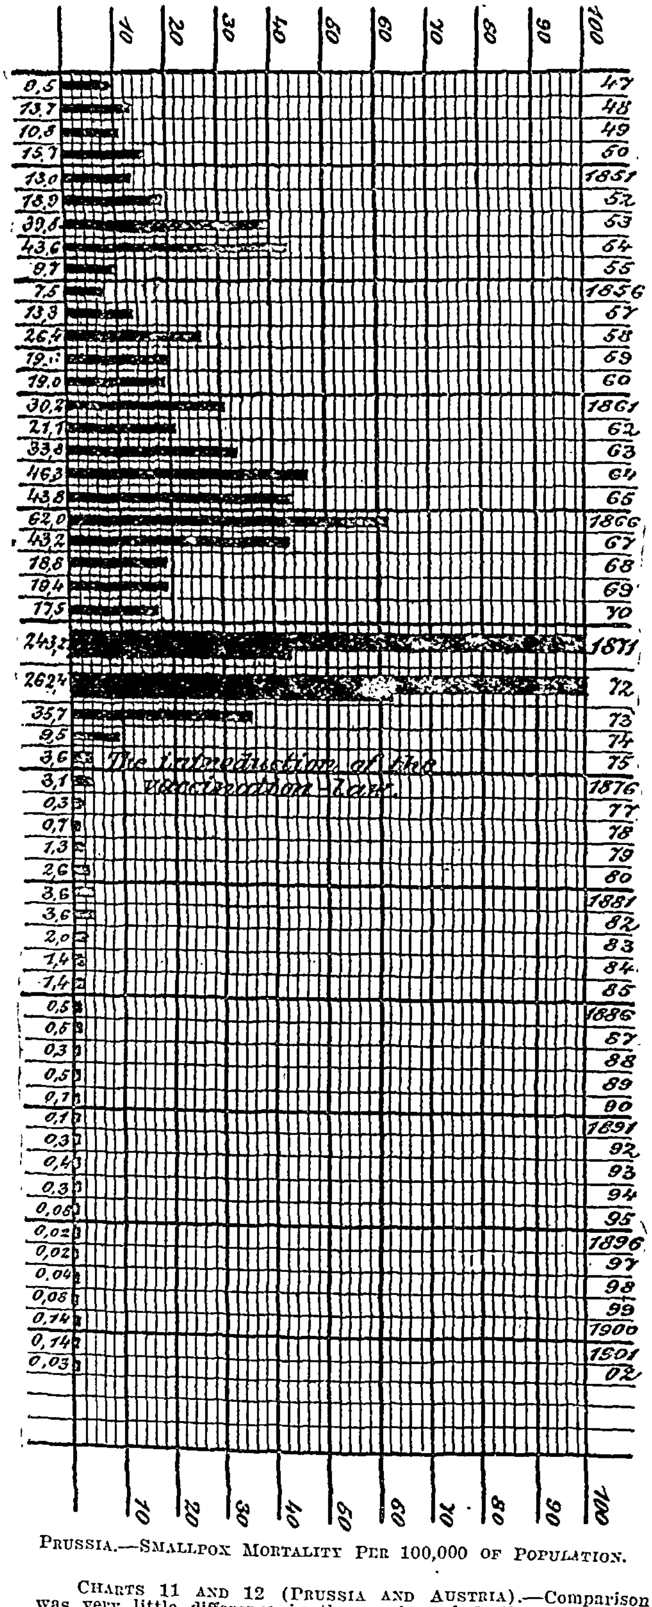
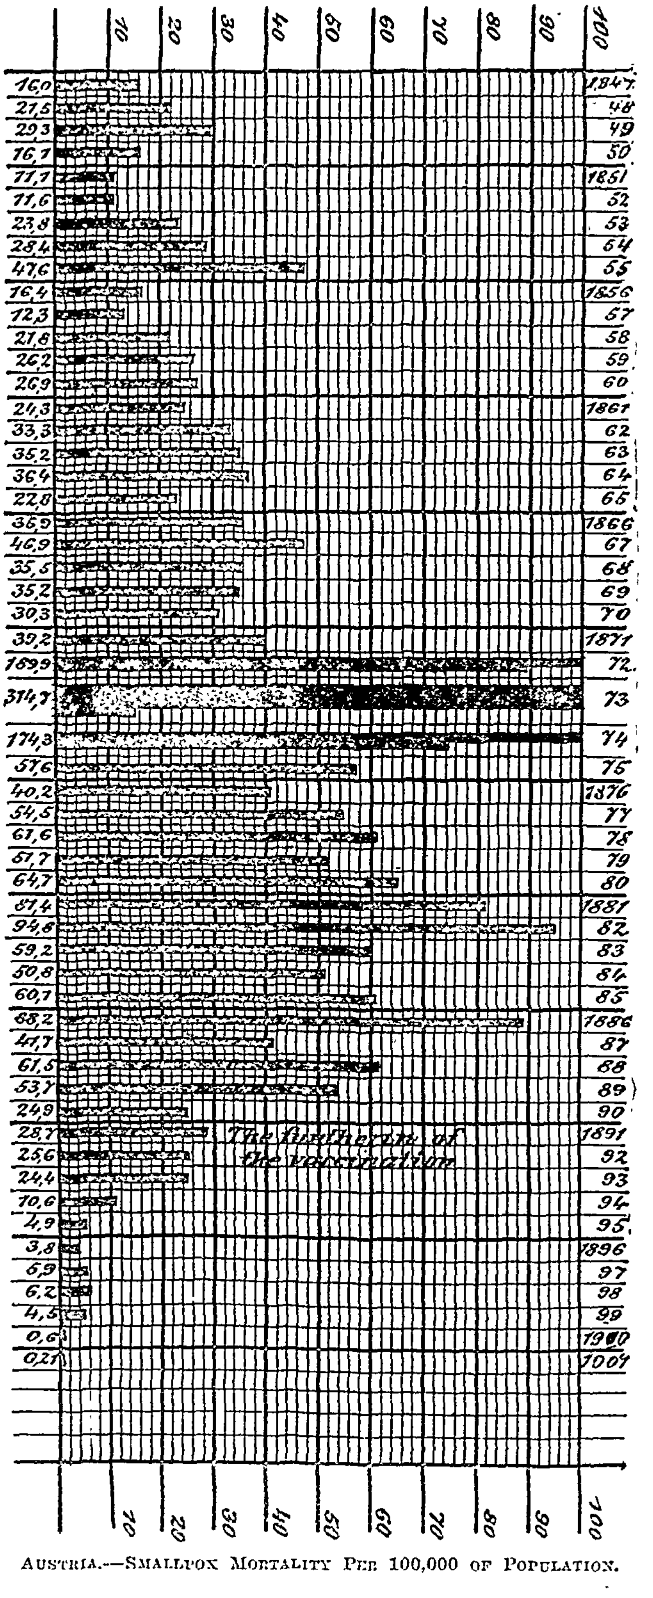
loss or attenuation of existing strains of lymph a fresh source may be obtained by variolation of calves. It has long been known that vaccine lymph may degenerate by too prolonged transmission through the human species. In years gone by the cry was often heard, "Back to the cow."

Again, in the event of a vaccine famine such as occurred in 1871-72, or in an extensive epidemic of smallpox in some inaccessible country where vaccine material could not be secured, the ability to convert the smallpox virus into vaccine virus by inoculation of calves would offer the means of suppressing the epidemic.



Prussia.—Smallpox Mortality Per 100,000 of Population.



Austria.—Smallpox Mortality Per 100,000 of Population.

Charts 11 and 12 (Prussia and Austria).—Comparison of mortality from smallpox during the years 1816-1902. There was very little difference in the number of deaths from the disease in the two countries as long as compulsory vaccination had not been introduced; since the enactment of the German vaccination law in Prussia, however, the mortality there has sunk to a previously unknown figure, whereas it has remained stationary and at the same high rate in Austria for many years. Up to 1889 the mortality from smallpox in the latter country was on an average greater than it was before the epidemic in 1872, and it is only since 1890 that favorable conditions have again prevailed, although the losses from smallpox have remained greater during recent years than in Prussia.

ADVANTAGES OF BOVINE VIRUS OVER HUMANIZED VIRUS

1. About a quarter of a century ago it was the common practice to employ for vaccination the fluid or the dried crust from the vaccine lesion on a child's arm. While such vaccinations gave satisfactory results as regards protection against smallpox, they were attended with certain disadvantages which are obviated by the use of bovine lymph. The use of calf-propagated virus precludes the possibility of transmitting by vaccination diseases peculiar to the human species. One of the most weighty reasons that led to the adoption of animal vaccination and to its preference over arm-to-arm transmission was the recognition of the possibility of inducing syphilis by vaccine inoculation. To be sure, such accidents were so rare that thousands on thousands of physicians vaccinating throughout a lifetime failed to encounter any such unfortunate experience. Nevertheless, no matter how uncommon such a catastrophe might be, the remotest liability of such an occurrence constitutes a serious argument against the use of humanized virus. The opponents of vaccination bitterly attacked the procedure on the grounds just mentioned. The bovine species being totally insusceptible to syphilis, the use of lymph of calf origin is entirely devoid of the danger of transmitting syphilis. The weightiest argument of those who have antagonized vaccination is, therefore, nullified. Erysipelas appears to be a much rarer complication since the general employment of animal virus.

2. The virus of calves offers an almost inexhaustible supply of lymph, inasmuch as a much greater yield can be obtained from the calf than from the human subject, and, furthermore, the number of calves used can be multiplied according to existing needs. During extensive epidemics of smallpox when humanized virus was employed, the community was often placed in a most embarrassing and dangerous predicament owing to an insufficient supply of vaccine lymph. During the great pandemic of smallpox that spread over the entire globe in the early seventies a veritable vaccine famine existed in many countries. All kinds of sources were drawn on for virus, and much worthless lymph derived from spurious and irregular vaccinations was employed, with entirely unsatisfactory results.

3. Animal lymph appears to give a much larger percentage of successful revaccinations than long-humanized virus. Dr. Henry A. Martin says:

> The number of those who in revaccination with old, long-humanized virus (not that of early human removes) experience vaccinal effect may be stated at the outside at 35 per cent. The number of those revaccinated with equal care and repetition with animal virus and virus of very early human removes, I affirm to be a fraction over 80 per cent.—a difference of 45 per cent.; and this 45 per cent. I firmly believe to represent approximately the number of those insensible to the ef[illegible]
> fluence of long-humanized virus, but s[illegible]

virus or virus derived by scientific men in France,
creates a more complete d Great Britain.

It has been alleged by the opponents of vaccination that tuberculosis has been and is transmitted by the use of calf virus. The precautions which are adopted in the propagation of vaccine virus make such an accident almost an impossibility. Even were this not the case, it is very doubtful whether an inoculation of virus contaminated with the tubercle bacillus would produce more than a local skin lesion which could be readily cured. The precautionary measures employed are, as has been said, an all-sufficient safeguard. The virus is obtained from very young calves, and it is pretty well established that calves are but rarely the subjects of tuberculosis. It is stated by Fürst,[19] on the authority of Pfeiffer, that but one case of tuberculosis was found among 34,400 calves under four months of age. The statistics of the abattoirs of Augsburg and Munich corroborate the above figures; only one tuberculous calf was discovered at Augsburg among 22,230 slaughtered, and the percentage was much smaller at Munich.

Furthermore, in all well-regulated establishments for the propagation of vaccine virus, the calves are subjected for a number of days prior to vaccination to the tuberculin test; in the event that tuberculosis is shown to exist in the animal, it is, of course, not employed for vaccination. All calves used for vaccination are autopsied and carefully examined before the virus obtained from them is placed on the market. Finally, even though it were possible, despite these precautions for the tubercle bacillus to contaminate the lymph, it would perish if the virus were glycerinated. Nearly all of the vaccine lymph now employed is subjected to the process of glycerination. Copeman,[20] speaking of glycerinated lymph, says:

> The tubercle bacillus is effectively destroyed even when large quantities of virulent cultures have been purposely added to the lymph.

EXPERIMENTAL RESEARCHES ON MONKEYS

A number of observers, including Zuelzer, Copeman, De Haan, Roger and Weil, Park, Ewing, and Councilman, McGrath and Brinckerhoff, have shown that it is possible to inoculate certain species of monkeys with smallpox, producing in them a mild affection similar to inoculated smallpox formerly induced for protective purposes in man. This inoculation protects the monkey against subsequent successful inoculation and likewise against vaccination. Monkeys are only slightly, if at all, susceptible to smallpox contracted in a natural way through the air. Professor Councilman, of Harvard University, and his associates allege that they have discovered the parasite which causes smallpox, the same
organism [illegible] modified being held to be present in

[illegible] by vaccination and r

2. Vaccination protects against smallpox in the same manner that one attack of the smallpox protects against a second attack. Vaccination has the special advantage in that the immunity which it confers against smallpox may be renewed when it becomes impaired or exhausted.

3. Vaccination in order to confer protection must be genuine: the mere production of a "sore arm" is of itself no proof that the subject has been successfully vaccinated. The vaccination must run a definite course before a protective substance is left in the body.

4. Smallpox may develop in vaccinated persons if they permit years to elapse without revaccination.

5. Vaccination and revaccination universally applied are capable of exterminating smallpox as an epidemic disease. The experience of Germany during the past thirty-five years proves this.

6. In isolated instances individuals in a generally well-vaccinated community may develop smallpox because their protection is imperfect as a result of the use of an inert virus or some other fault of technic. These cases, however, will never appreciably influence the prevalence of the disease in such a community.

7. Smallpox was an ever-present and terrible pestilence in the days before vaccination. In most civilized centers it is to-day a relatively rare disease. This change has been effected almost exclusively by vaccination. Epidemics of smallpox prevail from time to time when the spark of infection is introduced into the community and a sufficient amount of unvaccinated combustible material exists to lead to a general conflagration. In countries where vaccination is neglected, as in Persia, Asiatic Russia, etc., etc., smallpox is still a death-dealing scourge.

8. The foes of vaccination commonly refer to the infrequency of smallpox at the present day and to the remote liability of contracting the disease. They forget that the relative security which we now enjoy is the result of vaccination. This security can be made absolute or it can be largely destroyed according as vaccination and revaccination are generally employed or generally neglected.

9. The dangers connected with vaccination have been greatly exaggerated by the opponents of this measure. Vaccination causes an abrasion of the skin and in rare instances this wound, like other wounds may become infected, especially when neglected or maltreated. With the selection of a proper virus and care of the vaccination site during and after vaccination, the risk in any individual instance is an entirely negligible quantity. The risk connected with vaccination is infinitesimal compared with the peril of remaining unvaccinated.

THE RELATION OF ANIMAL RESEARCH TO OUR KNOWLEDGE OF SMALLPOX AND VACCINATION

1. Numerous experiments on calves have proved that smallpox virus may be converted into vaccine virus by transmission through several generations of the bovine species. This discovery not only establishes vaccination as a thoroughly scientific practice, but also provides for a new source of lymph in the event of the deterioration or loss of existing strains.

2. Experiments on calves have resulted in a method of calf vaccination which permits of the production of any needed quantity of virus. This renders unnecessary the use of humanized virus with the attendant disadvantages elsewhere referred to. The use of calves for the propagation of vaccine lymph constitutes the most important improvement in vaccination since its discovery over a hundred years ago.

AN EXPERIMENTAL STUDY OF CERTAIN PHASES OF CHRONIC BACKACHE

A COMBINED GYNECOLOGIC AND ORTHOPEDIC INVESTIGATION *

EDWARD REYNOLDS, M.D.
AND
ROBERT W. LOVETT, M.D.
BOSTON

DEFINITION OF CLASS OF CASES UNDER INVESTIGATION

For an indefinite time the medical profession has been confronted with a very common and perplexing class of cases, mostly in women, but occasionally in men, in which persistent backache is the chief subjective symptom.

These cases present the following symptomatic picture: The pain, generally dull in character, is as a rule referred to the sacral or lumbar region and is frequently felt in one or both sacro-iliac joints; rarely it is complained of in the dorsal region. It also frequently shoots down one or both legs, in which case it is generally classed as "sciatica" and is aggravated by forward bending or flexion of the thigh with the knee extended. The pain in the back and leg are aggravated by standing, and especially by prolonged standing, such as is involved in the fitting of women's dresses. It is sometimes relieved by the recumbent position, but at times is at its worst when the patient rises in the morning. The pressure of the hand in the small of the back while sitting, or the use of a cushion in the same region in sitting or lying, are instinctive means of relief which every practitioner has seen these patients use. The pain is most often aggravated during menstruation and in general is either unilateral or bilateral, but in the latter case on close questioning is usually found to be worse on one side than on the other. Local tenderness may or may not be present. If the back is exposed and the finger-tips are placed over the erector spinæ muscles, perceptible spasm may be excited in these muscles by voluntary forward or lateral bending at the waist, and perfectly normal spinal mobility is unusual in the more marked cases. Bending is frequently better performed to one side than to the other. The nervous element in these cases may be slight, or so severe as to dominate the whole picture.

The condition sometimes originates from accidents, such as falls; it begins at other times as the result of overuse or strain, as in prolonged piano-playing, after heavy lifting, or after surgical operations. At other times it is found without assignable cause. The affection is exceedingly persistent and seldom very severe, and its most striking characteristic feature is the patient's insistence on a habitual pain for which no adequate cause is apparent. A search for that cause was the purpose of this investigation.

PRESENT TERMINOLOGY

The causes of this condition have been variously assigned by specialists and the general practitioner to the pelvic organs, to the muscles and joints, and to the nervous system. The uncertainty concerning its true

---

* Portions of this paper were read in abstract before the American Gynecological Association in New York April 21, 1909, the American Orthopedic Association in Hartford, June 9, 1909, the Gesellschaft der ehemaligen Hoffa'schen Assistenten in Berlin, Sept. 6, 1909, and the Anglo-American Medical Association in Berlin, Sept. 11, 1909.

nature is expressed by the many names applied to the condition, of which the most common are the following:

Hysterical spine.
Neurasthenic spine.
Weak back.
Uterine backache.
Irritable spine.
Chronic lumbago.
Railroad spine.
Relaxation of the sacroiliac joints.

Among the laity the condition is often attributed to kidney disease.

Without denying the existence of cases in which this symptom is the result of diverse causes, such as actual uterine, spinal or sacro-iliac disease, we are inclined from the observations and experiments to be described to regard the term "static backache" as more truly descriptive of the majority of these cases. By which term we mean pain due to back strain incurred by an undue effort to maintain body balance under the conditions of the individual physiology.

ESTABLISHED TREATMENT

If the patient is a woman and any abnormality of her uterine system can be found, it is usually considered adequate reason for immediate treatment by the gynecologist. If some innocuous uterine peculiarity is operated on in order to cure a backache which is dependent on an overstrain of the back muscles, the results are not likely to be gratifying to the patient or to add much to the reputation of the surgeon who performs the operation. So, too, the orthopedic surgeon who devotes months of effort with apparatus and gymnastics to the relief of back strain caused by the faulty posture originated by inflamed pelvic organs is likely also to fail.

Outside of the gynecologic treatment, patients of either sex are treated by jackets, corsets, plaster strapping, splints, pads, springs, belts, massage, vibration, ymnastics. heat, electricity, etc. The application of h one of these measures is empirical and the method action of each is in general as little understood as the etiology of the condition for which it is used. If, instead of this blind work, a serious attempt is made to *investigate the causes of the condition and to study its* mechanics, it is possible that much confusion and many failures will be saved.

I. EXPERIMENTAL SECTION

REASON FOR PRESENT INQUIRY

The following experimental study, which has occupied us for the past three and one-half years, was undertaken because of the frequency with which one of us in gynecologic and the other in orthopedic practice met such cases of chronic backache, especially in women, and the study was made a joint one because we concluded that a consideration of the subject from our two different points of view would be more likely to be of use than two pieces of work done by each of us separately. No sooner had we started on our joint investigation, however, than we realized that neither of us had any exact comprehension of the causes or mechanism of the condition, matters which were evidently essential to any clear comprehension or study of the subject. We therefore turned to a study of the literature of the mechanics of the erect posture and found at that time little but vague statements, founded mostly on accepted authority rather than on observation of the living individual by reliable scientific methods. We were, therefore, obliged to begin our work by formulating for ourselves methods for the study of the mechanics of the maintenance of the upright position, and at the outset it became evident that any such study must start with a determination of the center of gravity of the body, and its relation to the supporting structures, because all lines of strain and all muscular balance depend obviously on such relations, and we desire here to express our indebtedness to Prof. Ira N. Hollis, of Harvard University, for advice generously given us on the mechanical side of our problem.

Our first two years and a half were, therefore, spent in a purely physiologic research, at the end of which time we had perfected an apparatus for determining the center of gravity in the erect living individual.[1] Up to the time of this, our contribution to physiology, there had existed, so far as could be learned from a study of literature, no reliable method of estimating the position of the center of gravity of the body in the upright position. Various loose statements as to its location are given in literature, and there are a few carefully formulated attempts to determine it by a study of the masses of the body post-mortem and their relation to each other, but scarcely any two writers agree as to what the erect normal posture should be.[2]

The method in previous use had been as follows: A cadaver was dismembered, the center of gravity for each arm and leg, the head and the trunk were separately obtained and, by a formula, the relation of these masses to each other in an ideal erect posture was calculated, and the center of gravity of the whole body in this posture was then located therefrom. From our observations we believe that the position of the center of gravity obtained in this way is misleading and untrustworthy for translation to the living, because the results obtained have failed so markedly to agree with the actual position of the center of gravity in the actual erect posture as obtained by us.

A study of the well-known method of Borelli for determining the center of gravity in the horizontal position suggested to us our method of determining the antero-posterior position of the center of gravity of the body in the standing posture; and the correlation of it to certain bony landmarks was easily added, as will be described.

AUTHORS' METHOD OF DETERMINING THE CENTER OF GRAVITY IN THE ERECT POSITION

On the platform of a dial scale registering up to 100 pounds is placed a sharp edge which supports one end of a flat board (B), the other end of which is supported by a similar sharp edge placed on a rigid block (C). The distance between the edges is 508 mm. (20 inches). A short distance behind the rigid block is placed an upright post (E) with a horizontal sliding arm (D, shown in section only), which furnishes a plane of reference from which the antero-posterior position of each of the important landmarks of the body can be determined by measuring their horizontal distance from this sliding arm.

The determination of the antero-posterior position of the center of gravity in the standing subject is made as follows:

The subject is weighted on an ordinary set of scales. He is then placed on the balance plane (B) at a known point facing the scales. (The exact point is unimportant, but after some experimentation we selected as most convenient that in which the heels are situated at one-fourth the length of the plane from the posterior sharp edge.) A removable ledge (F) against which the heels are placed is provided here.

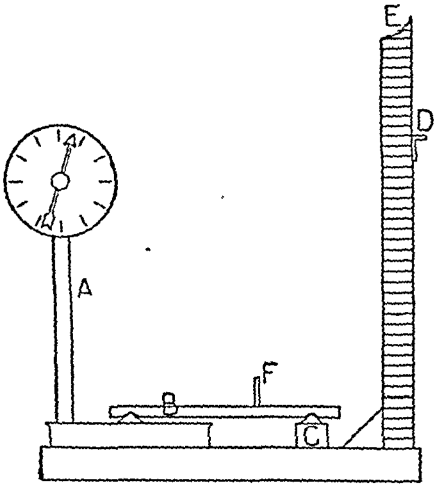

Fig. 1.—Diagram of the apparatus for estimating the center of gravity: A, scale. B, balance plane on which patient stands facing A. C, block supporting triangular edge. D, movable horizontal arm on upright for obtaining horizontal distances. E, vertical upright for standard plane. F, ledge against which heels are placed. (American Journal of Physiology.)

Since the balance plane on which the subject stands acts as a lever, in which the weight is borne between the fulcrum (the posterior sharp edge) and the supporting force (the spring which governs the scales), it is evident that the weight recorded on the dial (the balanced weight) will bear to the total weight the same proportion as that which obtains between the total length of the balance plane and the distance between the perpendicular dropped from the patient's center of gravity and the posterior end of the plane. That is: As the total weight is to the balanced weight, so is the total length of the board to the horizontal distance of the center of gravity of the patient from the posterior sharp edge (the fulcrum), or, to illustrate by a specific instance: The subject's total weight is 140 pounds; when placed on the balance plane his weight is 50 pounds, and the total length of the board is 20 inches.

The formula reads then:

$$\frac{140}{50} = \frac{20}{x}$$

This is then worked out as follows:

140)1000(7.1
980

200

The center of gravity of the subject then lies perpendicularly above a point 7.1 inches forward from the posterior sharp edge.

After the determination of the position of the center of gravity, which should occupy on an average one or two minutes, the position of the following points which have been marked on the skin are measured and recorded.

1. The position of the back edge of the malleolus.[3]
2. The position of the back of the head of the fibula.
3. The position of the middle of the trochanter.
4. The position of the posterior part of the spine of the fifth lumbar vertebra.
5. The position of the posterior part of the spine of the seventh cervical vertebra.

All these points are taken under the usual conventions of somatologic measurements on the living.

The measurements having been recorded, are then easily translated into graphic form by the reproduction of the observed measurements on a sheet of paper, of which the bottom represents the balance plane, and the edge of the paper the posterior plane of measurement.

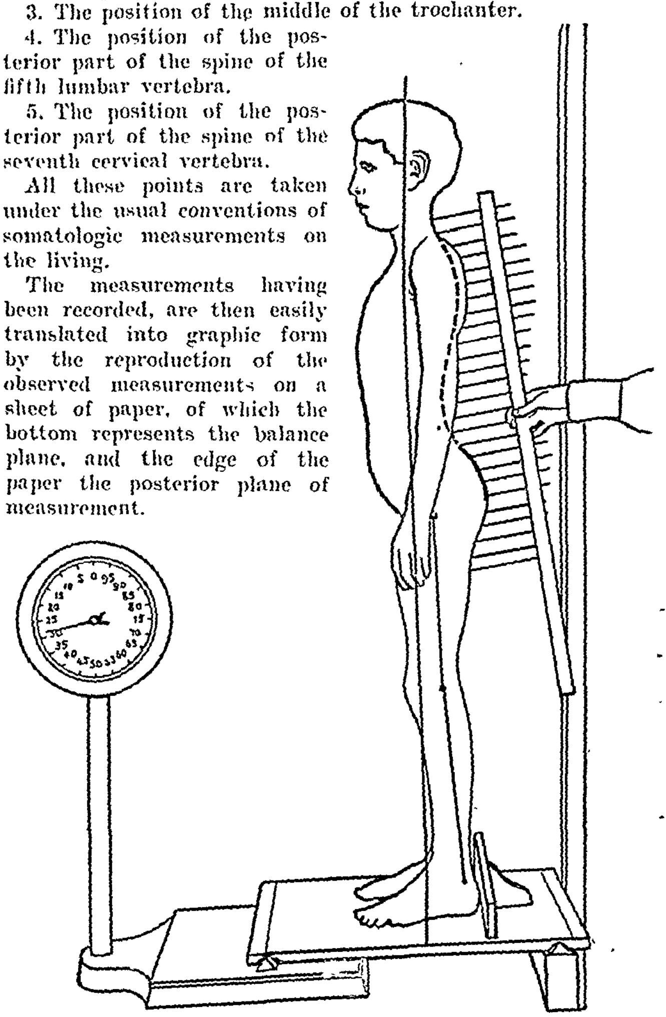

Fig. 2.—Apparatus in use. The lines drawn represent the lines shown in the record tracings. The long line running vertically is the perpendicular of the center of gravity.

These five comprise all the exact measurements which we have taken, but since the value of their graphic representation is considerably enhanced by its combination with some sort of representation of the body profile of the individual, we have completed the examination by the use of a device which obtains this with fair accuracy and which is illustrated in Fig. 2.

A series of horizontal metal arms, tipped with celluloid, slide easily through holes in the vertical wooden arm. These metal arms are shaken out to their full length, and their ends pushed rapidly and lightly against the subject's back in the median line, the point of the uppermost horizontal arm being applied to the seventh cervical vertebra. In the construction of the graphic record (Fig. 4), the position of this profile is known by its relation to the seventh cervical and fifth lumbar vertebræ; that is, these points are marked on the paper from the measurements taken, and the end of the uppermost arm of the profile instrument is laid against the mark which represents the seventh cervical, while a lower point is in contact with the mark representing the fifth lumbar vertebra. The curve is then traced on the paper containing the other measurements from the ends of the pins throughout its length.

The body curve of the ventral surface is obtained in the same way. The uppermost arm of the profile instrument is applied to the anterior surface of the neck at the level of the seventh cervical vertebra. The position of this curve on the chart is ascertained by using as points of reference the horizontal distances between the posterior parts of the seventh cervical and fifth lumbar vertebræ and the points horizontally opposite on the ventral surface, measured on the subject by a pelvimeter or other calipers.

---

[3] In this and the following determinations the horizontal difference is obtained by a footrule, one end of which is placed against the marked point, while the body of the rule is held by the thumb against the upper surface of the sliding arm. Since this surface (and therefore necessarily the rule) is horizontal, the height of the point observed may be read at the same time, from a graduated scale which is marked on the upright post.

It would be very desirable that this graphic record should be completed in every instance by a representation of the inclination of the brim of the pelvis, which would, of course, include its relation to the trochanter, but after much experimentation we have been unable to measure with accuracy the inclination of the pelvic brim in the living subject.

The use of the profile curves in the graphic representation involves the disadvantage that the chart must be drawn life-size, but it can be reduced later by a pantograph to any desired size. The change effected in an individual by treatment or apparatus may be most convincingly displayed by the repro- of its record on the same chart, as in the figures shown e clinical section later.

The sources of error incident to the method have been carefully studied. They are swaying of the subject, errors in measurement from the vertical plane, distortion of attitude during observation, inaccuracy in locating on the skin the bony landmarks selected, varying position of the feet, horizontal rotation of the pelvis and psychical influences. These errors and their prevention are dealt with at some length in the original description of the method, and therefore need not be repeated here.

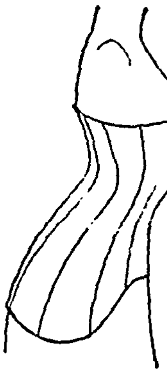

Fig. 3.—Outline drawing of bad corset applied to a model.

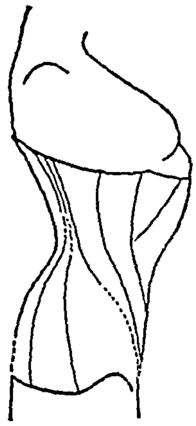

Fig. 6.—Outline drawing of good corset applied to a model

OTHER METHODS OF STUDY USED

At the beginning of our study we experimented with various methods which proved to be worthless for exact use. These were shadowgraphs, observations with plumb lines, study of the model standing on a glass plate by means of a reflected image in a mirror placed underneath and measurements from an upright without knowing the center of gravity. Photographs were largely used, at first without success, but later, by making two exposures on the same plate with the greatest care to prevent jar of the camera, two positions of the model could be recorded with accuracy, but any such composite photograph which showed any duplication of outline of the feet was rejected. Such photographs were mainly used in checking the accuracy of our results from our final apparatus.

Out of several hundred observations made mainly by the apparatus described, we finally selected two hundred as reliable for study, which form the basis of our present communication.

MATERIAL STUDIED

The study was made for the most part on female nude professional artists' models courteously sent to us by the School of the Boston Museum of Fine Arts. In the three and a half years some six of these were under observation, our study of one model at first lasting for months, while, toward the end, two or three were under observation during a fortnight. We selected female rather than male models because they were more easily obtained and more reliable, also because the condition under study occurs much more frequently in women.

Professional models, although clearly the only available material for our purpose, present certain disadvantages which we recognized. They are necessarily of stable types of figures, as otherwise the long-continued assumption of one position necessitated by their occupation would be intolerable, whereas we should have preferred to study women of the unstable types of figure. Another obstacle lay in their desire to help us, and we had carefully to conceal from them the purpose of our inquiry. Another difficulty lay in their ability and readiness to assume fixed unnatural positions, which in posing for artists they are, of course, compelled to do. We therefore supplemented the observations on these by such observations on patients as could be made without undue exposure, and a few such on normal persons, which have also been utilized in formulating our conclusions. These observations were then studied in detail, carefully correlated and analyzed.

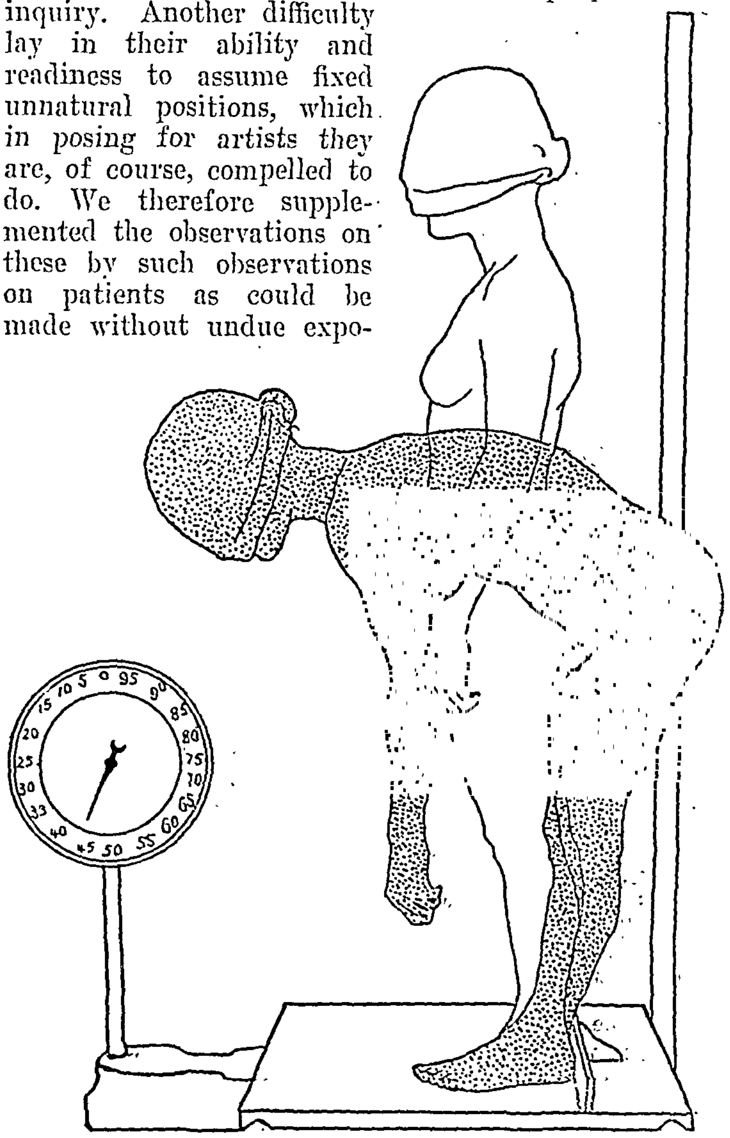

Fig. 8.—Drawing from composite photograph of model in two positions. The center of gravity is not changed in its relation to the feet.

DEFINITION OF FIELD OF EXPERIMENTAL STUDY

A consideration of the results of our physiologic study led us to the conclusion that antero-posterior balance in the upright position is maintained by moderate tonicity of the posterior musculature exerted against a slightly anterior position of the center of gravity. Reasoning from this led us to further experiments and observations, to be presently detailed, which seem to us to show that an important element in all static backache is to be found in back-strain, and that to assume relaxation of the sacro-iliac joints to account for the symptoms found is neither necessary nor wholly satisfactory. As soon, however, as we began to plan a series of observations relating to the question of balance, it became evident that the field was so large that we could hope to cover for the present only some one small phase of the subject, and after a survey of the whole field of inquiry opened by our physiologic research we decided to limit ourselves for this first paper to a study of the very suggestive question of why such backache was in our clinical experience frequently improved or relieved by the use of corsets or high-heeled shoes.

No one realizes more fully than ourselves how very small a portion of the whole field we have here covered, and our present contribution is regarded by us rather as a report of progress, possibly of therapeutic value, than as a final settlement of even the management of static backache. It is our intention to pursue the lines of investigation already undertaken further as opportunity may permit.[4]

Fig. 4.—Position induced by bad corset in dotted outline; normal in solid line. In this instance the shoulders are thrown back of the normal a little, but not so much as the hips. On this and all following records, the solid vertical indicates the original position of the centre of gravity, the dotted vertical the induced position.

Fig. 5.—Position induced by bad corset in dotted outline; normal in solid line. In this instance the shoulders are thrown forward of the normal and the hips back.

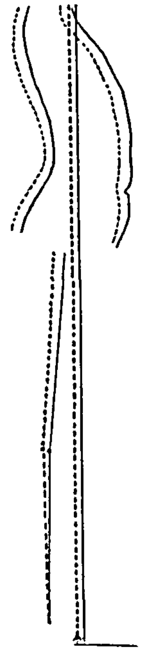
Fig. 7.—Position induced by good corsets in dotted outline. Normal in solid line. The apparent flattening of the lumbar curve in the dotted line is due to the bulging of the soft tissues through the open space at the back of the corset.

PRELIMINARY CONSIDERATION OF PHYSICS RELATING TO BALANCE

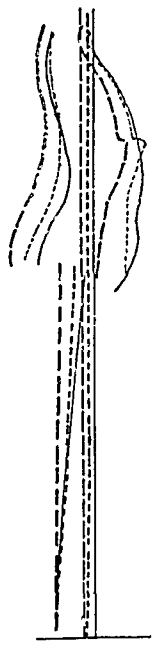
For the proper comprehension of the practical application of our experimental work to clinical conditions, it is necessary at this place to introduce certain elementary points in mechanics which are familiar to every one, for the preliminary problem under consideration resolves itself into an analysis of the mechanism of the standing position.

These points are the following:

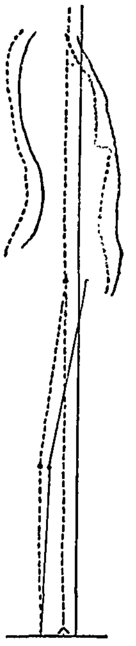
1. The base of support of the upright human figure consists of a trapezoid formed by the outer borders of the feet and lines connecting the back of the heels and the front of the toes.
2. The center of support lies perpendicularly under the center of gravity and must always lie within this trapezoid.
3. For the purpose of studying the mechanism by which any weight is borne by a solid body in unstable equilibrium, the entire weight may be regarded as concentrated in the center of gravity, and the determination of the relation between the center of gravity and the bearing points determines the lines of stress.



9



10



11

Fig. 9.—Record of the normal position and that induced by high-heeled shoes, the normal in solid line, the induced position in dotted line.

Fig. 10.—Record of normal position in solid line, corset position in dotted line and position of shoes and corsets in black line broken at longer intervals.

Fig. 11.—Record of Patient 4, whose backache was relieved by corset and Cook back splint. Original position in solid line; position of relief in dotted line.

Our observations show that in the erect position the center of gravity of the body lies in front of the ankle-joints, which are held from dorsal flexion in this position by the gastrocnemius muscles. The center of gravity lies also in front of the knees, which are similarly held in position by the hamstring and quadriceps extensor muscles. The center of gravity lies also anterior to the sacro-iliac joints and most of the vertebral joints. The position of the acetabula cannot be determined in the erect position in the living individual because we have no means of locating them from any available landmarks. If we were able to determine the position of the acetabula in the antero-posterior plane it would be possible to state definitely, from the relation of the center of gravity to them, whether the trunk in the erect position would tend to fall forward or backward at their level. But from the impossibility of obtaining definite data on this point: we are obliged to resort to another line of observations to determine this matter.

---

[4] 4. Other lines of investigation at once suggest themselves as likely to prove of value, especially from the point of view of the orthopedic surgeon. (a) The establishment of a "normal" for the standing position and the formulation of the normal position of the center of gravity is possible with a sufficient number of observations. (b) The relation of the line of weight to the foot may be of much importance. It is obvious that the further forward this line falls the greater will be the strain on the tissues supporting the arch. It may in the future aid in the diagnosis and treatment of static disorders of the feet. (c) The attitude of round shoulders is a vicious position of the entire body and not of the shoulders alone, and its treatment by gymnastics would be made more exact and efficient if the attitude were analyzed. (d) Some incidental experiments showed that the effect of corrective gymnastics must be studied by some more exact apparatus than the eye if they are to be correctly and efficiently prescribed. (e) The static conditions evidently underlying the ptoses of the various abdominal viscera form a most promising field of study.

It has been shown by many experiments that when the cadaver is stood erect and the legs and ankles are fixed (to prevent the cadaver from collapsing on the ground), the trunk falls forward from the hips. In the erect position then the trunk is held extended on the legs by the combined and continued action of the posterior musculature; the chief factors here being the hamstrings, the glutei and the erector spinæ muscles.

If, however, for any reason the center of gravity becomes displaced forward, the strain on the posterior musculature necessarily becomes increased throughout, because the vertical stress at each level is determined by he horizontal distance of that point from a perpendicular dropped from the center of gravity, and, if this moves forward, the strain increases in proportion to the increased horizontal distances. So, too, other things being equal, the points farthest away from this perpendicular suffer the greatest stress.

Having presented these preliminary considerations in mechanics, we come next to the report of our experimental observations on the disturbances of balance.

THE EFFECTS OF CORSETS ON BALANCE

Throughout our remarks on this subject, we desire that it should be remembered that our experimental studies were concerned only with balance and the modifications produced on balance by corsets and high-heeled shoes, and that the other effects of these are not discussed.

In our experimental work it early became apparent that the assumption of any enforced position for even the short time involved in an observation left behind it an alteration of the normal, or unrestrained position which persisted for a number of minutes; also that mere maintenance of the standing position resulted in the appearance, after a surprisingly short but variable time, f a modification of the normal which we designated as "fatigue position."

For these reasons it was necessary in our corset work to take a fresh observation of the normal attitude before each corset observation, to insist that each corset observation should be followed by at least fifteen minutes' complete muscular relaxation in a recumbent posture, and to limit the number of corset observations in any one sitting to two at most.

In their effects on the antero-posterior position of the body, corsets may be divided into three classes and each class must be studied separately if clear results are to be obtained. After much unsuccessful search for a satisfactory nomenclature for these three classes we have adopted the brief and comprehensible, though somewhat unscientific terms: the neutral, the bad, and the good corset.

A. Neutral Corsets

The indifferent or neutral class includes the great majority of all corsets worn by women, but it must be remembered of this statement that it applies only to the effects of corsets on balance, posture and static backache. Many of the posturally indifferent corsets may be harmful in other ways. Few of them are beneficial. At the present time practically all ready-made corsets belong to the posturally indifferent class. Indeed, we found it necessary to have good and bad corsets specially made for each of the models with whom we experimented. Until we did this, our results were confusing, but after this precaution was taken the results of observations on all forms of corset became uniform, consistent, and sufficiently evident to permit of clear record and definite deductions. Neutral corsets produced no appreciable effect on body balance.

B. Bad Corsets

We use the term "bad corset" to designate that whole class of corsets the use of which we have learned to associate clinically, and to some extent experimentally, with the existence and production of static backache. All corsets of this class have definite common characteristics. All produce the same effect on posture when submitted to exact observation, varying only in the degree of their results. All tend to increase or produce static backache if persistently worn.

The common characteristics of this class of (bad) corsets are as follows: 1. They are long behind (especially at the top) and short in front (especially at the bottom). 2. They are cut to exert their greatest pressure at the waist and at the top and bottom are capable of exerting pressure only against the wearer's back. 3. They have strongly marked sacral curves, but are otherwise straight in the back, and are highly incurved at the waist in front.

Figure 3 is an outline of a representative specimen of the bad corset made from life by a very competent artist. The bad corsets uniformly moved the center of gravity back and effected an important alteration of posture. To the unaided eye this usually appeared as a simple movement of the shoulders forward, but this effect, though very constant, was in fact an illusion. When their action was measured and recorded it proved that they really threw the shoulders slightly backward, but always much less than the hips, which were thrown far behind the normal, thus inclining the line of the back forward and giving the illusion of forward shoulders.[5]

Figure 4 and Figure 5 show the effect of the bad corset.[6]

C. Good Corsets

The forms which we class together as the good corset have equally definite common characteristics and effects on posture. They are all in greater or less degree beneficial to those who suffer from static backache.

The common characteristics of all the forms which we class as good corsets are (1) that they are short behind (especially at the top) and relatively long in front (especially at the bottom); (2) they fit the wearer tightly around the pelvis (especially in the space between the iliac crests and the trochanters) and decrease regularly in pressure to their upper edge where they are very loose (especially behind); (3) they are considerably incurved at the waist line at the back and sides, but show no waist curve in front. Figure 6 is a life sketch of such a corset. The good corsets invariably moved the center of gravity back, and in all our experiments they threw the shoulders back of the normal, but under their effect the hips never moved further backward than did the shoulders and sometimes less. Figure 7 shows the actual effects of the good corsets as recorded.

It will be seen that, though both the bad and good forms of corset move the center of gravity backward in its relation to the base of support (the feet), they affect its relation to the more important bearing points of the body in directly opposite ways, a fact which explains their bad and good effects on back-strain and static backache.

---

[5] In a few instances, the shoulders were unmoved or thrown very slightly forward, but always with strong backward displacement of the hips.

[6] The bad effect of a corset is not necessarily dependent on stiffness and we have seen the posture described as characteristic of bad corsets induced by badly cut "hygienic" waists.

In connection with the effect of the bad corset Figure 8 possesses illustrative interest. This is an accurate outline reproduction of a composite photograph. The model was first told to stand at ease on the balance plane, then to bend forward, and exposures were made of each position on the same plate. The dial of the scale was included in the plate and was found to rest at the same point in both attitudes. The model (who was entirely ignorant of the purpose of the experiment) had instinctively preserved her normal balance, and the relation of the center of gravity to the base of support was unaltered, but its relation to back-strain is seen at a glance to have been utterly different. The stippled position in Figure 8 is, in fact, only an exaggeration of the position induced by bad corsets (compare Fig. 5) as contrasted with the normal, the inclined position of the back subjecting the posterior musculature to increased strain in the dorsal and gluteal regions. No one will doubt that the erect position is one of comparative ease to the posterior musculature, nor that the forward bent position would produce backache if long persisted in.

SELECTION AND MANUFACTURE OF PROPER THERAPEUTIC CORSETS

The recommendation of any specific make of corsets is impossible, even if for no other reason, because there is no make of corsets appropriate to all figures; and there is no make of corsets which remains stable under the changing fashions. There have been times in the past when most of the ready-made corsets belonged distinctly to the bad type. There have been periods in the past when the ready-made corset frequently tended toward the good effect. At the present time, as has been said, most ready-made corsets are inefficient or neutral. A ready-made corset of more or less neutral type can often be so altered by taking up its seams that it produces a fairly good effect, and this can be increased when necessary by the use of a Cook's back splint,[7] but the manufacture of a good corset by a skilful corsetière to fit the individual wearer is preferable when practicable.

In the production of the desired effect which should be produced by a "good" corset three points are important: 1. It is essential that the more important seams run diagonally forward and downward in order to secure the proper lines of strain in the cloth. 2. The bones which serve to keep the corset from wrinkling should run in such directions as not to interfere with these strains. 3. The patient should be taught to apply it properly after it has been properly made. These points seem to us so important that they are presented somewhat in detail.

1. In having corsets made for patients the easiest method of obtaining therapeutic results is to have the corset brought to the office after it has been cut and stitched together, but before it has been boned. It should then be somewhat large for the patient, and, after being placed on her, should be made to fit her by pinching up the seams one by one and securing them with pins. In Figure 6 the seams which are especially likely to need tightening in this way are marked with a broken line. The corset when completed should fit very tightly in the space between the trochanters and the iliac crests. This anchors the corset and in many figures prevents its riding up without the use of the objectionable front garter. It should merely fit the patient over the iliac crests and immediately above them, as tightness at this point is uncomfortable and makes the corset ride up. In the back it should fit the hollow of the waist snugly, being hollowed in at the back, but not at the front, and above the waist it should be left as loose as the patient will wear it. In the front it should be straight, without constriction at the waist.

2. The anterior bones should run from above downward and strongly forward.

3. To be properly applied a corset must be laced in three sections, sacral, lumbar, and dorsal. Before it is put on, all the lacings must be widely loosened. The corset must then be settled into place as low as it can be worn, and clasped. The patient should then pass the hand inside it and lift the abdomen into it, settling the front of the corset as low as possible. The lumbar lacing should be pulled comfortably snug. The sacral lacing should then be made as tight as can be borne, and if the corset is so made as to spare the iliac crests, and properly cut out for the thighs in front, very tight lacing around the solid pelvis is comfortable to the patient. The dorsal lacing should be left as loose as is comfortable.

The clinical tests of the completed corset are that it should be comfortable to the wearer and that it should produce to the eye of the observer the effect illustrated in Figure 6.

THE EFFECT ON BALANCE OF HIGH-HEELED SHOES

The question of body balance as affected by shoes of different kinds has been ably discussed by Cook of Hartford, and our results by measurement correspond closely to those reached clinically by him.[8]

In speaking of high-heeled shoes, it should again be particularly noted that we are speaking only of the effect of such shoes on balance and not of their effect on the foot. Our observations dealt with the effect on balance of shoes with heels varying from 1½ to 2¼ inches in height.

Preliminary experiments with composite photographs and the balance apparatus led us to the belief that raising the heel of the unshod foot by means of a book placed underneath tipped the body forward, and that compressing the front of the bare foot by a bandage without raising the heel tipped the body balance back, and we inferred that the effect of the high-heeled shoe was merely the resultant of these two opposed elements. But with the perfection of our apparatus we found that neither of these two component effects was constant, whereas the effect of the high-heeled shoe was constant. After a long series of experiments it became evident that high-heeled shoes tip the body back as a whole without making any appreciable change in the lumbar curve. Figure 9 is an instance of these records. There was but one exception to this effect in our observations on high-heeled shoes. This was in a rather degenerate type of girl whose center of gravity was naturally abnormally far back, and it is probable that her inability to tip further back without falling, forced her to compensate by forward muscular effort against the shoes. This was, at all events, the only exception among many observations.

One possible source of experimental error must be mentioned, for the sake of possible future observers, in connection with this conclusion that the body is tipped back by high-heeled shoes. In overlaying the tracings for comparison the malleoli must correspond rather than the toes or heels. Without this precaution the mechanical distortion due to the oblique position of the foot in high-heeled shoes would lead to evident error.

---

[7] A leather support reinforced by light steels bent to fit the back and support the lumbar curve where the corset lacings fail to give the support afforded by the rest of the corset.

[8] Cook, Ansel G.: The Question of Balance, Am. Jour. Orthop. Surg., July, 1907, and May, 1909.

THE EFFECT ON BALANCE OF HIGH-HEELED SHOES AND CORSETS COMBINED

Our observations on the combined effect of high-heeled shoes and corsets opened up a very complicated question that we have not yet been able to solve satisfactorily, although it is a more important question clinically than the others, because the combination of high-heeled shoes and corsets is what one meets clinically. In all of our experiments, moreover, we found that models in corsets, and most markedly in bad corsets, were much more comfortable standing in high-heeled shoes than without them—a fact confirmed by clinical experience. In our work on this point each observation was taken of the model without shoes or corsets, then with corsets of one of the various types, and then with both the corsets and shoes. The *three tracings were then overlaid for* study. The mechanical complications involved were so many that at present we are not prepared to make a more definite statement than that the use of high-heeled shoes seems to modify, toward the individual's normal, the position induced by corsets and particularly the position induced by bad corsets, already described. Figure 10 shows a record of this combination.

Finally, in this connection, we would protest against the indiscriminate advice so generally given to patients with backache to avoid high-heeled shoes. In many instances coming under our observation, such a change has been followed by most uncomfortable results.

DEDUCTIONS FROM OBSERVATIONS

Our conclusions from the experimental part of our paper are: that the center of gravity can be determined in the living erect individual; that this center of gravity is so located in relation to the supporting structures that the erect position is maintained by the tonicity of the posterior musculature; that forward displacement of the center of gravity leads to increased demand on the posterior musculature to maintain the erect position.

In the position induced by what we have designated as the good corset, the strain on the posterior musculature is lessened by displacing the center of gravity backward, and more especially by the fact that the shoulders are moved back at least as far as are the hips.

Though the bad corset also displaces the center of gravity backward, the relief to the posterior musculature which would be expected from this is neutralized in the position which they induce, by the fact that the pelvis is moved much further backward than the shoulders, thus inducing an inclined position of the back in which the weight of the trunk, considered by itself, is thrown so far forward as to place undue strain on the posterior musculature of the lumbar and pelvic regions.

In the position induced by the wearing of high-heeled shoes, without any other modifying apparatus, the strain on the posterior musculature is relieved by motion of the center of gravity backward, through movement of the body backward as a whole, *chiefly from the ankle*-joint.

The study of two forms of modifying apparatus applied to the subject at the same time introduces so much complication of conditions that conclusions therefrom must be drawn up with great caution. When high-heeled shoes are observed in conjunction with either form of corset we conclude that the attitude characteristic of either form of corset is modified slightly toward the normal of the individual by the addition of high-heeled shoes, but the analysis of the effect so produced involves so complicated a mechanical study that we are not yet prepared to publish conclusions as to why this effect is produced.

II. CLINICAL SECTION

The clinical section of our paper is best introduced by the presentation of a few personal illustrative cases selected from many similar ones and reported in abstract for economy of space.

ILLUSTRATIVE CASES

Case 1.—Patient, single, 53 years old, was sent to E. R. by a prominent orthopedic surgeon for backache and sense of weight in the abdomen which in spite of evident static faults had been uncorrected by his treatment, and which he was acute enough to believe must be traceable to some pelvic condition. On examination it was evident that her forward posture was due to an unconscious attempt to lessen pressure on a fibroid which *nearly filled the true pelvis, and that the orthopedic* apparatus had been ineffective in correcting the attitude or in relieving symptoms because it had been applied in the face of the determining cause, the fibroid. The patient made a prompt convalescence from a hysterectomy, but on rising from bed was extremely discouraged to find that the backache, which had led her to seek treatment, was, if anything, worse than before; but when she returned to the orthopedic surgeon who had originally treated her he found that the same apparatus which had before been ineffective now gave prompt relief, and after a few months she was able to drop it gradually. When last heard from, some time afterward, she was entirely well without treatment.

In this case orthopedic treatment was unsuccessful till the primary cause was removed. Hysterectomy alone might ultimately have relieved the backache without orthopedic treatment. Backache was, however, immediately and permanently cured by orthopedic treatment following the operation.

Case 2.—Patient of E. R., married, aged 35, had undergone three major operations and prolonged local treatment without relief at the hands of three very prominent gynecologists, the chief symptoms being renal pain and sacral backache. The operations were nephrorrhaphy, anatomic success, with therapeutic failure, and two suspensions, both of them anatomic and therapeutic failures. Prolonged trials of pessaries had been made by two of the gynecologists, always ineffective, and always increasing pain and backache. Evident static faults, too complicated for the gynecologist to treat, were present and the patient was referred to the orthopedic surgeon of her choice after she had positively declined to allow replacement of the uterus and the insertion of a pessary on the ground of her previous experience. After considerable orthopedic treatment she was relieved of all her symptoms except sacral backache, which continued distressing. She then allowed E. R. to insert a pessary, which for the first time in her history she wore not only without pain but with immediate relief of the backache, and after wearing it for several months became able to maintain a forward position of the uterus without the pessary. She is still under orthopedic treatment but is relieved of her symptoms. Orthopedic treatment should have preceded an operation.

The names of the other medical men connected with these cases are omitted for obvious reasons.

Case 3.—Patient, sent to E. R. by Dr. Chandler of Medford in January, 1908, 40 years old, married; no children; dysmenorrhea always; dyspareunia always; indigestion with intestinal gas three years; frequent frontal headache; occasional not very severe neuralgia in left sacrosciatic region, along the distribution of the left sciatic nerve and over the inner surface of the left thigh, always increased by walking and standing, but almost constant before and during catamenia. Pains and aches in all portions of the body. Patient did not seem in very bad condition, but was very self-centered, running from one specialist to another. On examination pelvic organs were normal. Diagnosis, orthopedic disability. Patient was told that she should consult an orthopedic surgeon but that her many specialists should be under the control of a neurologist whom she should see frequently and persistently; referred to Dr. J. J. Putnam with consent of Dr. Chandler with written opinion to this effect; referred by Dr. Putnam to R. W. L.

Examination by R. W. L. showed that the patient stood with a slight left lateral curve and in a general "slumped" attitude. The lumbar region was flat, the dorsal region rounded and the knees were inclined to be held slightly flexed. She complained that she felt as if her back were not hollow enough; and to get relief she assumed a position with more lumbar curve in which the knees straightened. She showed marked tenderness over the left sacroiliac joint and felt some pain in the left leg. A radiograph showed that the sacroiliac joints were normal.

She was provided with properly fitted therapeutic corsets giving marked support in the lumbar region and which were tight around the pelvis, and was started on exercises. She was not markedly improved by this treatment at the end of a month.

Orthopedic treatment having failed to afford relief, Dr. Putnam put the patient under general rest-cure methods in a hospital. His observation there convincing him that the left-sided pain was genuine and persistent, and its catamenial exacerbation pronounced, he requested another examination from E. R. Examination without anesthesia was again negative, but under anesthesia the presence of a slightly enlarged, hard, non-tender left Fallopian tube was demonstrated, and a few days later the abdomen was opened. The left tube proved to be straight and patent, but with much thickened and indurated walls; the corresponding ovary slightly enlarged, sclerotic, and containing a very large number of small tense cysts scattered through it like a charge of birdshot. The left ovary and tube were removed, and abdomen closed. Normal convalescence. Patient declared that all abnormal sensations in left side had disappeared. On getting up there was, however, some left-sided sacroiliac backache, relieved by a therapeutic corset. Patient returned to Dr. Putnam's care. When last heard from, one year after operation, she considered herself well.

In this case the essential factor was at first missed and the case considered orthopedic. After longer observation the detection and cure of the abdominal lesion resulted in spontaneous relief of the apparently static symptoms.

Case 4.—Patient of R. W. L., a healthy and well-developed young woman, a professional teacher of gymnastics, at the end of a very hard year developed severe sacral backache for which advice was sought. She was at the time wearing a small girdle. She was treated by corsets and one of Cook's back splints. The pain disappeared immediately and an observation was made showing that the center of gravity had been moved back 1½ inches. This change was so great that a second observation was taken a week later for purposes of verification with identical results (Fig. 11).

The relief was permanent and the case was evidently one of pure back-strain induced by overexertion and therefore relieved by the change of balance and consequent relief to the posterior musculature without further treatment.

Case 5.—Patient of R. W. L., a married woman, 34 years old, of rather less than average physique, had been fairly well until her confinement a year and a half previous. Shortly after getting about she began to have pain in the back and in one leg, and standing was accompanied by great discomfort. She had lost flesh and was very nervous and apprehensive. Examination indicated that the backache was apparently static. She had been treated by osteopathy without success, and later the diagnosis of a relaxed sacroiliac joint had been made. For this a plaster-of-Paris jacket had been applied and worn without any relief of the pain. When she was seen she wore a steel back-brace and a neutral corset. An attempt was made to throw the center of gravity backward by means of a properly made corset reinforced by a light tempered steel back brace to throw her balance back; this gave immediate comfort, and gentle exercises were begun. In three weeks she was practically free from pain, had gained in flesh and was improving as to her nervous instability.

In this case of evident back-strain the use of the ordinary appliances to splint the back did not give relief, which was obtained by changing the body balance by corsets.

APPLICATION OF EXPERIMENTAL DEDUCTIONS TO CLINICAL CONDITIONS

It becomes evident from the most casual consideration that in this class of cases there exist two elements, the gynecologic and the orthopedic, and an analysis of the probable primary cause of the pain, therefore, becomes necessary.

That forward displacement of the center of gravity induces increased effort of the posterior musculature (back-strain) has been demonstrated in our experimental section. That such excessive or prolonged muscular effort may be translated into pain, spasm and irritability is not only more or less a matter of common information, but may be supported by quotation of certain well-known analogous instances. If the arm is held out horizontally, after two or three minutes the muscular effort is translated into an ache. The spasm and irritability of the ciliary muscle which is overstrained to accommodate for astigmatism is well known. The pain and dragging in pronated and flat feet is generally admitted to be due to muscular and ligamentous strain.

That back-strain sufficiently long continued, induced by an unduly forward position of the center of gravity may be translated into backache seems evident. The unduly forward position of the center of gravity which induces backache we believe to be usually caused by one of three factors:

1. Peculiarities in the form and proportions of the skeleton (not necessarily outside of normal limits) resulting in a type of figure with a center of gravity markedly far forward.
2. General muscular relaxation leading to a "slumped," relaxed attitude.
3. Tenderness of intra-abdominal or intrapelvic organs inducing the patient to assume a stooping or other strained position to relieve intra-abdominal or intrapelvic pressure.

The gynecologic cases described above belong in the latter class and, though it is evident that the field of intra-abdominal or other visceral lesions which may cause such attitudes is wider than that covered by any merely gynecologic cases, yet they are presented as the most frequent representatives of a large class for the purposes of this paper.

It is further evident from the anatomy that in the case of the comparatively unprotected sacro-iliac joints even the painful spasms of the dorsal musculature may, and probably do, fail to prevent painful tension on the connective tissue (ligaments and fasciæ) placed there to regulate extremes of motion. Without denying the occasional existence of abnormally movable sacro-iliac articulations (mostly puerperal) we believe that undue tension on connective tissue from overstrain is sufficient to explain the symptomatology of most cases of apparent functional derangement of the sacro-iliac joints without invoking the possible existence of an abnormal mobility to explain it further.[9]

DIFFERENTIATION OF CASES AND TREATMENT

Our observations would be of little value to ourselves or to others were we not prepared to formulate certain conclusions governing the treatment of these cases. It is evident that a determination whether the original cause of the backache is primarily intra-abdominal or originally static is a necessary preliminary to intelligent or effective treatment. In practice, in the comparatively limited field selected by us for discussion here, the cases would seem to fall schematically into three classes:

---

[9] It has been a matter of common observation that pain in the back, of the character described, may be induced by lateral inequalities of the skeleton producing lateral strain, e. g., a short-leg; and during this series of observations we have been confronted by numerous instances of it. We feel sure that such lateral inequalities predispose to the unilateral (one-sided) localization of pain induced primarily by bilateral strain, but we have thought it necessary in this series of observations to limit ourselves to the one point of antero-posterior strain and have therefore recorded no observations on this issue.

1. The gynecologic, of intrapelvic origin.
2. The orthopedic, of mechanical or static origin.
3. The borderland cases in which both elements are present, or in which the differentiation between the two is at first impossible.

The recognition of a borderland class is necessary on account of the frequency of its appearance in clinical work, but the line between this and the other classes is so indefinite that it can be described only by implication under the other headings.

1. Treatment of Cases of Intrapelvic Origin

Static backache is frequently a prominent symptom of the intrapelvic neoplasms. It is then due to an alteration of attitude caused either by an instinctive effort to lessen pathologic pressure within the pelvis, or by disturbance of balance from the actual weight of the larger growths. In these cases no improvement in the static condition can be expected until after the removal of the neoplasm, and here an immediate operative removal should be promptly followed by proper orthopedic treatment if necessary.

On the other hand, many of the ptoses are merely secondary results of static abnormalities. In these cases especially, gynecologists should be careful not to adopt treatment without first making a study of the static causes which so often have produced, or are perpetuating them, since some previously unmanageable retroverted uteri, prolapsed ovaries, etc., can be promptly relieved by minor intrapelvic treatment after the static faults which caused them have been corrected. Ptoses of the kidneys and other upper abdominal viscera are equally important and should be considered. Under these conditions, also, those cases which still demand major measures will more surely become symptomatic as well as anatomic successes, and many anatomic failures will be avoided.

In the inflammatory affections of the pelvic organs the instinctive efforts of the patient to protect the tender structures from the pressures and jars which are always incident to locomotion in the erect posture, lead usually to so persistent a maintenance of a constrained attitude that the prominence of static backache in these cases is easily understood in the light of what has been said in our experimental section.

The relative value of static or intrapelvic treatment as an initial step in the management of these cases depends largely on the stage of acuteness at the time at which treatment is undertaken. It is generally conceded that during the presence of an acute symptomatology the inflammatory affections of the pelvic organs should have depletive and soothing rather than radical treatment. In the more acute cases the muscles of the back are almost invariably in a state of irritation and spasm, and no part of the initial palliatory treatment is more important or more promptly grateful to the patient than rest in bed, support to the irritated muscles, hot packs, the local electric light bath, etc., for their relief. On the other hand, even in the chronic cases, too early attempts at mechanical correction of the faulty posture are apt to do harm rather than good so long as the pelvic tendernesses are unrelieved, since if successful they again expose the tender organs to the pressures from which the faulty attitude has partially relieved them.

The complication of ptoses with inflammatory conditions demands evidently the weighing of relative indications in the individual case.

It is manifestly impossible to cover within the length of such a paper as this, even in outline, the whole field of gynecologic practice in its relation to static backache (even without the equally important lesions of general abdominal surgery), but we hope that what has been here said may serve to illustrate the principles involved.

The gynecologist may, of course, readily examine the backs of his patients and may with practice acquire some facility in the differential diagnosis of back-strains into those of primarily intra-abdominal or primarily static origin, but he should never forget that in the static cases the abnormality which is the original cause of the symptom may often be found in a distant part of the skeleton (e. g., the feet), and that its detection may require special knowledge.

Throughout the field of gynecologic practice the estimation of static conditions is of importance whenever backache is a symptom.

2. Treatment of Cases of Mechanical or Static Origin

The orthopedic surgeon will be wise to refer to the gynecologist for a preliminary examination and opinion by which to guide treatment, those cases in which the history, or the replies to the usual questions, are suggestive of uterine disease. This is especially important when the symptoms suggest the possible presence of inflammatory disease of the intrapelvic organs, since in these cases, as has been said above, alteration of attitude, such as would be indicated by the back-strain alone, may be distinctly harmful.

The accepted orthopedic treatment of back-strain as it exists to-day has been already spoken of in the beginning of the paper. It is a matter of common information that it is on the whole unsatisfactory. The treatment which from our point of view should be in theory the most satisfactory, and which in practice in our hands has proved the most successful, is as follows:

A defect of balance exists which in the end must be cured by remedying that defect of balance, a matter only to be brought about by substituting a correct for an incorrect attitude. Massage and gymnastic exercises to induce this correct attitude would seem to be the obvious method to follow. But practically this alone at the outset is generally unsatisfactory for the following reasons: One is dealing in most instances not with athletes with well-developed muscles, but with men, or more often women of less than average physique as a whole, whose back muscles in particular are overstrained, weak and irritated. These patients are recumbent not over ten out of the twenty-four hours as a rule, and for the rest of the time are generally sitting, standing, or walking. To begin by gymnastics on muscular development under these conditions is to exercise still further for perhaps half an hour daily, muscles already overused, and for the remaining fourteen hours of the twenty-four the irritation induced by the malposition goes on, for a correct position cannot at once be substituted for an incorrect position. It is a frequent experience to find the backache made immediately worse by such treatment, even when given by skilled persons. It is as if the oculist ordered his patients suffering from eye-strain due to astigmatism to use the eyes a little more each day to strengthen them before he corrected the visual error. The best results in back-strain are to be obtained, not by attempting to strengthen irritated muscles at the outset by further use, but by temporarily putting them at rest by relieving the strain of the posterior musculature.

A properly fitting corset with a tight pelvic hold not only improves balance, but incidentally serves as a splint and support. The blacksmith who is to do heavy work with his arm puts a leather strap around his wrist to enable his muscles to work to better advantage. He gains thereby an extra annular ligament.

Proper corsets, then, accomplish three things in the relief of this condition:

1. They tend to correct vicious balance by carrying the center of gravity backward, thus relieving muscular strain.
2. They partially splint the lower back.
3. They furnish an artificial annular ligament to the glutei muscles.

High-heeled shoes are also to be recommended temporarily, when comfortable to the patient, because experimental observation has shown that they carry back the center of gravity, and clinical experience is generally confirmatory of their good effect.

If lateral deviation of the spine exists, it is to be improved by an extra lift on the shoe of the side to which the body leans.

In the more severe cases the active day should be a short one and recumbency for some hours during the day should be insisted on. It is only necessary to allude to the fact that the general condition of the patient must, of course, be attended to from the outset. After a week or two of such treatment, aimed at resting tired and irritated muscles, the patient is generally ready for the second stage of the treatment, muscular development as a means to the attainment of a permanently correct attitude. In irritable cases the exercises should be given at first in the recumbent position and later only in the erect position. The whole tendency of most medical gymnasts is to overdo both the massage and exercise at first. It must be remembered that the maximum muscular stimulation from massage is reached at the end of five minutes[10] and that, after that, deterioration of muscular strength follows. Increase of backache following the exercises is a sign of too active exercises or too long a period of them. They are best taken once a day, the length of the period being gradually increased.

It must be admitted that, irrational as it is, many cases of backache are relieved by the use of corsets and high-heeled shoes alone. In a larger number this is a most useful preliminary to further attempts at radical cure, and we must remember that we shall be really curing such patients only when we have found and removed the condition which caused the disturbance of balance inducing the back-strain.

CONCLUSIONS

We believe that static backache is essentially a mechanical disorder; that is, that it is the result of a loss of balance producing local strain on the tissues in the lumbosacral region and elsewhere in the posterior musculature. We further believe, and regard it as our most essential point, that whatever the local mechanism which produces the symptoms may be, such backache is in a large proportion of all cases not a disease in itself (as suggested by such terms as "hysterical spine," "relaxation of the sacro-iliac joints," etc.), but is a mere symptom-complex due to an abnormal attitude induced by peculiarities of the skeleton, lack of proper muscular balance, or abnormal conditions in the abdomen or elsewhere. We believe that in diagnosis the local condition should be regarded as primary only after every cause elsewhere has been excluded.

THE EFFECT OF ETHER ON CERTAIN PROCESSES OF IMMUNITY.[*]

EVARTS A. GRAHAM, M.D.
Nicholas Senn Fellow in Surgery in Rush Medical College
CHICAGO

The following study was undertaken as a part of a more general problem on postoperative lung complications suggested to me by Dr. Arthur Dean Bevan. An attempt was made to investigate the effect of ether on the phenomena of bacteriolysis, agglutination and phagocytosis. The clinical cases studied have been chosen from the surgical services of the Presbyterian Hospital. Squibb's anesthetic ether was used.

Because of the ease with which marked fluctuations of the bactericidal and agglutinating powers of a serum may be determined with the use of the typhoid bacillus, the work to be described concerning the effect of ether on bacteriolysis and agglutination was carried out with this organism. In each case experiments were conducted *in vitro* by adding ether in varying amounts to both normal and immune typhoid serums and also *in vivo* by observing the effect of ether anesthesia on these properties of the serums of practically normal human individuals, normal rabbits, and rabbits which were immune to the typhoid bacillus. The experiments on bacteriolysis were conducted in the usual manner by counting the number of colonies on agar plates after incubating the mixtures of serum and bacteria for variable periods. Sterile corks were used in the tubes instead of cotton plugs in order to minimize the evaporation of the ether while in the incubator. Varying amounts of ether up to 1 per cent. were used in different experiments. In none of the work was there observed any appreciable effect of the drug on bacteriolysis. The observations of the effect of the drug on agglutination were made with both the macroscopic and microscopic methods. Here also no alteration of the phenomenon was produced when ether was present in any amount from 0.1 per cent. to 2 per cent., or after an ordinary ether anesthesia.

In the work on phagocytosis it was found that ether, when added to both normal human and rabbit serum *in vitro* in varying amounts of from 1 per cent. to 2.5 per cent., reduces markedly the phagocytosis of streptococci. Similarly a reduction of phagocytosis was observed to occur after an ordinary ether anesthesia both in the human and rabbit. This reduction *in vivo* was demonstrated with *Streptococcus, Pneumococcus, Staphylococcus aureus, B. coli* and *B. typhosus.* For the study of the effects of the anesthesia on human individuals, cases were taken which involved fairly simple operative procedures on comparatively healthy young adults. Precautions were used to rule out factors which might complicate the results, such as infection, hemorrhage, shock, etc. The experiments on normal rabbits were carried out by subjecting them only to an ether anesthesia without operative measures of any kind. In this work the usual opsonic technic was employed. The reduction of the phagocytic power of blood after an ordinary ether anesthesia continued in different experiments over periods of two days' to several weeks' duration. This depression apparently was due to a direct effect of the ether on both leucocytes and serum, not to any effect on the bacteria themselves. The effect on the leucocytes was determined (1) by noting a greater decrease in phagocytosis when the patient's leucocytes were used in the experiments than when normal leucocytes were mployed, and (2) by observing on a warm stage a minished amount of ameboid motion and less phagocytosis of carmine particles by leucocytes subjected to the action of ether. The direct effect on serum was made evident by experiments to determine the comparative opsonic sensitizing power of normal serum and of a mixture of normal serum and ether. Streptococci were added to both the normal serum and the mixture containing ether, and after thirty minutes' incubation the bacteria were washed free from the serum by centrifuging in three changes of 0.85 sodium chlorid solution. They were then added to normal leucocytes. Much greater phagocytosis occurred when normal serum had been used for sensitizing than when the serum and ether mixture had been employed.

[10] McKenzie: Exercise in Education and Medicine, Philadelphia, 1909, p. 47.

[*] This work was carried out in the Surgical Service of the Presbyterian Hospital and in the Memorial Institute for Infectious Diseases. A report of the work was given before the Section on Pathology and Physiology of the American Medical Association, at Atlantic City, June, 1909.

In seeking for an explanation of these phenomena the interesting hypotheses of Meyer[1] and Overton,[2] that the anesthetic action of the fat-solvent drugs depends on their "mechanical affinity" for the fat-like substances of the body, seemed to afford a possible means of making clearer the mechanism by which ether reduces the phagocytic power of blood. Particularly did this theory seem to furnish at least a working hypothesis in the light of esults, very similar to those described here, which have een obtained by other workers with the use of alcohol and chloroform, drugs which have a pharmacologic action very similar to that of ether and are also fat-solvents.

Of particular interest in this connection is the work of Rubin,[3] who showed that hypodermic injections of alcohol, ether and chloroform render rabbits much more susceptible to systemic infections with streptococci and pneumococci, and that *in vitro* alcohol and chloroform diminish phagocytosis of pneumococci, streptococci and staphylococci.

Stewart[4] has shown that in normal human beings the ingestion of only a small amount of alcohol markedly lowers the opsonic index to the streptococcus and tubercle bacillus. Other observers have obtained results which to some extent agree with these just mentioned by showing that animals to which alcohol and ether have been given succumb much more readily to experimental infections than controls; particularly is this the case with those infections of which the immunity is chiefly phagocytic. Moreover, the clinical fact has long been recognized that alcoholism predisposes to such diseases as pneumonia, erysipelas, etc., in which phagocytosis plays a part.

Accordingly experiments were conducted to determine whether or not the fat-solvent power of the ether is the property by means of which it is capable of inhibiting phagocytosis. The problem was attacked by noting (1) the effect *in vitro* of the addition of a fat to blood, the phagocytic power of which had been reduced by the admixture of ether; (2) the effect *in vitro* of the addition to normal blood of ether previously saturated with a fat; and (3) the effect *in vivo* of injecting a fat into an animal subjected to an ether anesthesia. At first, lecithin was used because it is a fat-like substance which is almost universally present in the body. It was found that when lecithin was added in small amounts to the blood which had been subjected to the action of ether a prompt restoration of phagocytosis occurred. When ether was previously saturated with lecithin and then added to normal blood no diminution of phagocytosis was evident. Finally, when 0.1 gm. of lecithin was injected subcutaneously into etherized rabbits the phagocytic power of the animals' blood was restored to its preanesthetic condition in a few hours, whereas control rabbits which received a similar amount of physiologic salt solution showed a depression of phagocytosis which extended over a period of many hours. With the idea in mind that these results were not necessarily specific for lecithin, and that they might be obtained by the use of other ether-soluble substances, similar experiments were performed with olive-oil, a fat of widely different nature. Similar results were obtained, but it was found that in general more of the olive-oil was required to produce the effect. Moreover, it was observed that the injection of suitable amounts of the oil into the rectum was followed after three to six hours by a restoration of phagocytic powers, while, on the contrary, the injection of the same amount of physiologic salt solution had no appreciable effect in shortening the period of phagocytic depression. In the human experiments 5 ounces (160 c.c.) of warm olive-oil were passed slowly into the rectum through a tube immediately after the patient had returned from the operating-room.

The question has been raised why the injection of so small an amount of lecithin as 0.1 gm. should have an effect in restoring phagocytic power. A rabbit of 1,300 gm. weight may be assumed to have 100 gm. of blood, of which the plasma amounts to 52 gm. Hoppe-Seyler's analyses show that for 1,000 parts of plasma there are but 1.2 parts of fat. Therefore, in 50 gm. of plasma there would be 0.06 gm. of fat. Accordingly I have injected into each of my rabbits an amount of lecithin practically equal to twice the total amount of fat in his plasma. Of course, by a subcutaneous injection I do not get this amount into the circulation immediately, because fats are absorbed slowly from subcutaneous injections. However, I place something in the animal to which the circulating blood comes, and it is reasonable to assume that fat, when thus added in an amount equal to twice that normally in the plasma, may be capable of extracting from the blood a considerable amount of ether. I think the action of olive-oil per rectum may be explained in a manner similar to this, although since by the work of H. J. Hamburger and Edsall and Miller it has been shown that the large intestine can absorb a considerable amount of fat within a few hours, we might assume that at least a certain amount of the oil which we inject actually enters the blood-stream.

Another factor which concerns us here is that in all probability a certain amount of ether is present in the intestinal tract which may be held by the fat and thus prevented from becoming reabsorbed. Bongers has shown that chloroform is excreted into the stomach, and other workers have shown that it may be found in the alimentary tract after anesthesia. Although I am unaware that any investigation on this point has been carried out as regards ether, nevertheless, it seems reasonable to suppose that ether, too, gains access to the alimentary tract.

[4] Stewart: The Influence of Alcohol on the Opsonic Power of the Blood, Jour. Inebr., 1907, xxiv, 197.

These results cannot be interpreted as proving beyond a doubt that ether inhibits phagocytosis by means of its fat-solvent power, but they are extremely suggestive that such is the case. The important rôle of fat-like substances in the phenomena of one of the other immune reactions, viz., hemolysis, has been shown by many investigators, and when it is considered that a disturbance of the lipoids of the cell may involve marked changes in its surface tension it seems not unreasonable to assume that such may be the explanation of the action of the fat-solvent drugs on the phagocytic system, at least as regards the leucocytes. The question then arises: Is the serum element of the system dependent on or identical with the lipoid content of the plasma? Is either opsonin itself, or opsonic complement, a fat-like body? This seems to be answered in the negative by two series of experiments which show (1) that when lecithin is added to a mixture of salt solution, washed corpuscles and bacteria, no more phagocytosis occurs than without lecithin: and (2) that the addition of lecithin fails to reactivate serum, the complement of which has been destroyed by heating at 56 C.

To what extent these results may have a practical bearing on the explanation and prophylaxis of postoperative infections it is impossible to say with certainty at this time. It is realized that from a limited number of observations no far-reaching conclusions bearing on a practical application can be made.

A CYSTO-URETHROSCOPE *

LEO BUERGER, M.D.
NEW YORK

The great impetus given to the study of the posterior urethra by the invention of the Goldschmidt irrigation urethroscope has aroused hopes that still further improvements in the method of seeing the neck of the bladder and the posterior urethra could be expected. About one year and a half ago I attempted to overcome some of the shortcomings of the Goldschmidt and of other instruments by the employment of the Nitze type of indirect or right-angled telescope. By the adoption of an appropriate optical system and a new type of illumination I succeeded recently in constructing an instrument which gives a practically "normal" view of the trigone, neck of the bladder and posterior urethra. The shortcomings of the Goldschmidt instrument are well known. They are, briefly, a partial field, a distorted image and a large fenestra with its tendency to cause traumatism.

These have all been overcome in the new instrument, which consists of a sheath, obturator and telescope. The sheath is provided with a detachable beak, a small fenestra and two irrigating-cocks. The source of illumination in the original models was a lamp fitting into a globe which partly occluded the distal end of the window. In the new model (Figs. 1 and 2) an illuminating prism is employed. It is the same type of prism (Wappler) used in the telescope, but it is much larger. Its roof is backed like a mirror, and it doubly reflects the rays from the lamp, transplanting the source of illumination to the roof of the sheath, and bringing it in juxtaposition with the "eye" of the telescope. The telescope is furnished with the same type of prism which, however, is a "lens prism," one end being ground into a convex lens. The roof and the greater part of its floor, with the exception of the entrance pupil at the apex, are mirror surfaces. Figure 3, A and B, illustrates the difference in action of the Nitze-Otis and the new prism. In the latter we obtain upright images. The telescope is fitted eccentrically in the sheath and hugs the roof so as to carry the entrance pupil far away from the fenestra and, therefore, from the parts to be seen. With this telescope it is possible to reduce the size of approaching objects to such an extent that a perfect view of near objects can be obtained.

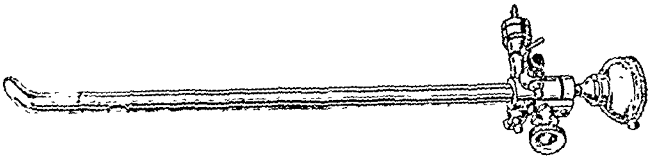

Fig. 1.—Sheath and telescope of cysto-urethroscope.

TECHNIC

The sheath with the obturator *in situ* is introduced into the bladder. Irrigation through the sheath, if the contents are cloudy, is next in order and then the telescope is inserted. *The introduction of fluid from now* on is carried on through one of the lateral cocks either with a Janet syringe or an irrigator. If the trigone and ureters are to be inspected I inject about 200 c.c. of boric acid. If the examination is limited to the neck of the bladder and posterior urethra, about 50 c.c. will suffice. The instrument is withdrawn and rotated, so as to gain a view of the whole of the sphincter. Then the floor of the posterior urethra can be seen, rotation of the instrument permitting observation of the lateral walls. By distending the urethra the images become smaller and magnification is produced at will by allowing the walls of the urethra to collapse. The roof and lateral walls are then brought into view by the same maneuver, the fenestra having been pushed into the bladder and turned upward. Throughout this process no traumatism is inflicted because of the small size of the fenestra. Practically every structure in the posterior urethra can be recognized; the colliculus, prostatic ducts and orifice of the utriculus can be seen in all cases. *After a little practice the ejaculatory ducts can be recognized.*

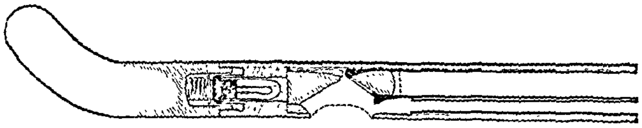

Fig. 2.—Diagram of sheath with telescope inserted.

Further uses of the instrument are the following:

1. The substitution of a long beak will permit of the examination of a very long posterior urethra, and the replacement of the curved beak by a blunt tip will allow its use for the anterior urethra.

2. Supplied with a short beak, or even as it is, the instrument could be used for inspecting the trigone and

---

* Presented at the Section of Genito-Urinary Diseases, New York Academy of Medicine.

ureters of bladders that hold but very small amounts of fluid, 30 to 60 c.c.

3. Topical applications can be made after removing the telescope and drying out the sheath.
4. Double ureteral catheterization can be easily done, and a delicate filiform bougie can be passed into the utriculus or ejaculatory ducts under the direct control of the eye.
5. Treatment can be also carried out under direct control of the eye; a fine forceps or a galvano-cautery electrode be passed through the space below the telescope.

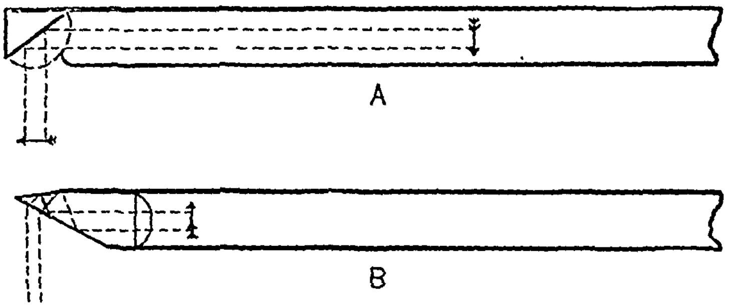

Fig. 3.—Action of Nitze-Otis (A) and new prism (B).

The advantages of the instrument are the following:

1. A perfectly normal view of the ureters, trigone, neck of bladder and posterior urethra can be obtained.
2. The amount of irrigation is reduced to a minimum; constant irrigation is unnecessary; intermittent injection of a little fluid suffices.
3. The small window makes rotation of the instrument possible and injury of the urethra is avoided.
4. By means of a new type of prism perfect illumination is provided and upright images are produced.

63 East Nineteenth Street.

EAR, NOSE AND THROAT SYMPTOMS IN DIABETES *

OTTO J. STEIN, M.D.
CHICAGO

In discussing ear, nose and throat symptoms in diabetes, it is assumed that all physicians are sufficiently conversant with a knowledge of the general pathology and symptomatology of the disease to render unnecessary any further reference to them. Furthermore, it is understood that what follows relative to this subject appertains to that variety of diabetes commonly understood as diabetes mellitus, and, although cognizant of other varieties of diabetes, erroneously designated as such, but which, in fact, are transitory glycosurias, produced by a multiplicity of causes, they have no special interest in this connection and at this time. In order to epitomize the subject, I will restrict this article to a discussion of the symptomatology of the ear, nose and throat.

Of the many manifestations of diabetes mellitus, it is a matter of surprise that the changes occurring in the mucous cavities of the head and neck should pass unrecognized, or, at least, without suspicion. This may be attributed to their seemingly trivial or unimportant character, but at the same time the fact that the cavities of the nose, throat and ear are easily accessible to examination furnishes sufficient reason for a more thorough interpretation of the changes that occur there, for by this means we may be led to early recognition of the disease. The participation of these cavities in this disease is by no means uncommon, although it is difficult to trace an unassailable array of signs and symptoms characteristic of the disorder. Nevertheless, one can catalogue a list of symptoms built on a knowledge of the general pathology, as we now understand it, that are of practical value.

In the mouth, evidences of perverted nutrition are frequently found about the teeth. Pyorrhea alveolaris and delayed healing after extraction are often associates of diabetes mellitus. The secretions of the mouth become distinctly acid in reaction, so that they act on the necks of the teeth, exposing the deeper and more sensitive parts to the ever-present infection within the mouth. The saliva itself, according to a number of observers, contains no sugar, but the sugar in the blood tends to increase the local infection, so that excessive deposits of lime salts, spongy and bleeding gums and carious teeth, causing aching teeth, are symptoms of importance in diabetes. These facts are now recognized by progressive dentists to the extent that the presence of diabetes in many cases can be diagnosed by them.

Aphthous stomatitis, thrush, a large red tongue, at times covered along the center by a black fur, hyperemia of the mucous membrane of the mouth, which at the same time looks glazed and feels dry, are frequent symptoms. When acetone is present in quantities, a distinct characteristic odor is imparted to the breath, which has the scent of acetic ether. The patient may even be aware of a sweetish taste. In a few cases sialorrhea, or excessive saliva, in place of the usual dry mouth, has been noted present in pancreatic disease, and hence may be suggestive of diabetes. A blunted sense of smell and taste have, in some instances, been recorded in this connection, and this is altogether possible as a sequence of the perverted metabolism.

In the throat, we are frequently confronted with the symptom of dryness, and when this is of a persistent nature it constitutes the leading symptom of this disease in this locality. This pharyngitis sicca is not to be interpreted as analogous to pharyngitis atrophica, for in the former the dryness is most likely "due to a modification of the chemical constituents of the glandular secretions," as Kyle says, and not to a true atrophy of the mucous glands and interstitial contractures, as in the latter. In the dry pharyngitis of diabetes the mucous membrane usually appears red and the secretions, in place of flowing, adhere, giving the surface a glazed appearance, like varnish. So important is this symptom to some observers that Moritz Schmidt says that in his experience a pharyngitis sicca, associated with such symptoms as mental hebetude, lassitude, furunculosis and cramps in the calves of the legs, is positive of the diagnosis of diabetes mellitus.

Although in a large number of cases it seems as if few structural changes take place in the tissues of the throat, exceptionally ulcers develop which bear a resemblance to those of tuberculosis. It is not an uncommon observation to find pulmonary tuberculosis complicating a diabetes mellitus, but few references are made to such an association in the throat. Hence it may be that when ulcers are present, especially with pharyngitis sicca, they may be tuberculous in character, although, to theorize, one might suggest that the altered secretion that dries may abrade the membrane, and thus precipitate infection, which is favored by the saccharine character of the

---

* Read in a symposium on Diabetes before the Chicago Medical Society, Jan. 19, 1910

fluid of the tissues. These ulcers, according to Freudenthal, may occur on tonsils, pillars and the posterior wall of the pharynx. They are painful, but heal readily, and for this reason he concludes that they cannot be tuberculous.

Of external signs about the nose, it is of interest to note that von Neusser says, in reference to cyanosis in diabetes: "There are some cases of chronic diabetes with a slight cyanotic reddening of the ears and nose, resembling an alcoholic with a weak heart."

As to intranasal symptoms, nothing characteristic has been noted. Most writers on rhinology make scant mention of the subject. It is my belief that there are a number of cases presenting symptoms of intranasal irritation, such as hyperemia, hypersecretion, itching, sneezing and paresthesias, that, if carefully worked out, would show a relationship to diabetes mellitus. Kyle refers to two cases of diabetes mellitus in which there was acute coryza, which diminished as the amount of sugar lessened, and returned with its increase. An interesting case of nasal hydrorrhea in a case of glycosuria has recently been related to me by Dr. Brawley, which lends color to the possibility of such symptoms in diabetes. Kyle refers to ulcerations of the nasal mucous membrane occurring in diabetes, especially around the nasal orifice, where the itching causes rubbing and picking, the amount of sugar seeming to influence their growth.

The manifold variety of ear symptoms in the presence of diabetes often comes as a surprise to the casual observer. A manifestation often shown about the external ear is the presence within the canal of one or more furuncles. Here, as in furunculosis of different association, the essential cause is the *Staphylococcus pyogenes aureus*. In diabetics the sugar in the body tissues is peculiarly favorable to the growth of the micro-organisms, and, as the meatus of the ear is a constant habitat of the staphylococcus, the pruritus present in this disease gives occasion to frequent abrasion, with consequent infection. In cases presenting the history of recurrent furunculosis, it is well to investigate the composition of the urine.

Otitis externa diffusa chronica may be present, particularly the desquamative variety. Eczema auris is not an uncommon ear complication, and when present is prone to be very extensive; besides involving the auditory meatus, it may present itself in the various fossæ on the anterior aspect of the auricle; on the posterior surface of the auricle, particularly in the deep fold where it is attached to the head, and at times on the adjacent skin of the neck and scalp.

In all cases of extensive eczema auris other than those traceable to middle-ear discharges, I routinely subject the patient to an examination for diabetes, and thus frequently find the causative factor. Gangrene of the auricle occurs on rare occasions, and may be due to a peripheral neuritis, as taught by Auché.

Suppurative ear disease in the presence of diabetes is always a serious complication, but not necessarily an alarming one. The question as to a pathologic entity ascribed to diabetic otitis media and mastoiditis is still debatable. Kuhn, Kerner and MacCuen Smith are of the opinion that primary mastoiditis in diabetes is a fact, while Eulenstein, in an analysis of almost seventy cases, fails to find sufficient corroborative evidence to warrant the foundation of a special pathology in these cases. No doubt the mucous surfaces of the ears, like those of the nose and throat, are subjected to the likelihood of congestion by the elimination of toxins, and their secretions may also become perverted and easily infected. The mucous membrane of the Eustachian tube, tympanic cavity, mastoid antrum and cells, when affected by this congestion, secretes an excess of mucus that is highly susceptible to bacterial contamination, which consequently means a mucopurulent and sanguinolent product. Besides the congestion, there is a tendency to hemorrhage and extravasation in the submucosa and deeper tissues. Serous effusions and hemorrhage in the drum membrane may occur similar to that seen in Bright's disease. In such cases the pain is of short duration, but the acuity of hearing, being blunted, is the symptom complained of. A bleb of varying size, usually that of a millet seed, and of a dusky purple hue can be seen on the surface of the drum membrane. If it is ruptured, it may be mistaken for a perforated drum membrane of acute middle-ear origin. An otitis media that appears suddenly without apparent cause should lead to an investigation for diabetes. It has been my observation that in such cases little or no pain precedes a spontaneous rupture of the drum membrane, followed by a profuse discharge. The mastoid seems to be almost invariably involved. Kuhn, one of the earliest writers on this disease, speaks of the frequent occurrence of middle-ear suppuration in diabetes, and says that the discharge is profusely purulent, with a tendency to a sanguinolent character, and that the mastoid becomes extensively involved, as well as rapid involvement of the labyrinth. Bönninghaus says that in diabetics, in a very short time, extensive disintegration of the mastoid process takes place; often the first blow of the chisel through a brownish discolored cortex exposes a large granulating cavity, involving the entire process from tip to antrum, and even to the inner table. Both ears may become simultaneously involved, and extensive involvement of neighboring parts may occur.

Numerous instances are cited wherein, owing to the liability of bone caries and necrosis in these cases, the suppurative process creates a meningitis, phlebitis, thrombosis and brain abscess. Suppuration of the labyrinth is usually secondary to a suppurative process in the middle ear, and is not uncommon in the presence of diabetes. Friedrich, in his monograph, *"Die Eiterung des Ohrlabyrinths,"* concludes that about one suppurative labyrinthitis results in about every hundred cases of suppurative otitis media, and Bezold places diabetes mellitus as second in the list of chronic systemic causes of suppurative labyrinthitis. The cardinal symptoms of labyrinthine disease, namely, profound deafness, tinnitus and disturbances of equilibrium, both static and dynamic, may furnish the clew to some variety of labyrinthine involvement in diabetes, be this involvement due to hyperemia, hemorrhage or suppuration.

To reiterate, suppurative otitis media and suppurative labyrinthitis are commonly associated in diabetes, and hence we should be alert in all diabetics with otitic involvement for symptoms of panotitis.

In closing, I wish to refer to the neuritis of the acusticus in diabetes. Of the many well-known causes of neuritis causing deafness, such as loud noises, drugs, toxemias, rheumatism and constitutional diseases, among which may be mentioned diabetes, syphilis, malaria and typhoid fever, the former, namely, diabetes mellitus, is mentioned by Bönninghaus as the most frequent of all causes of such neuritis.

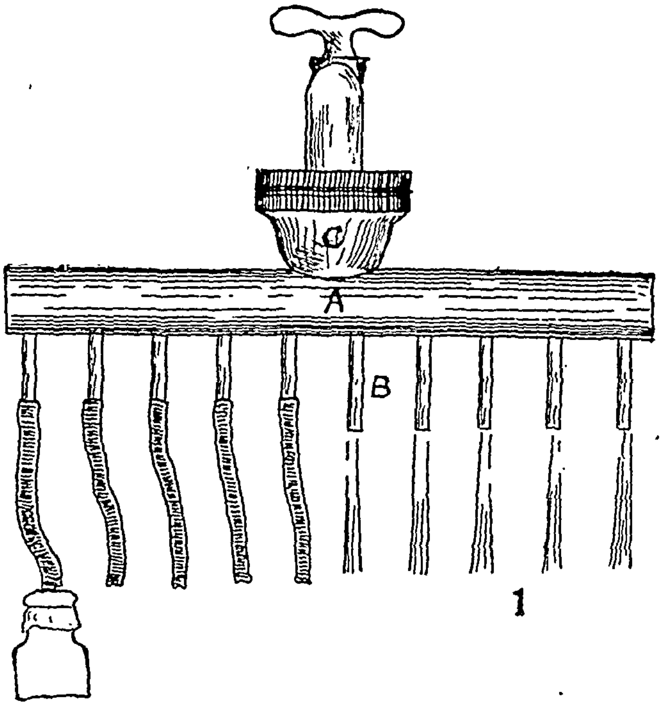
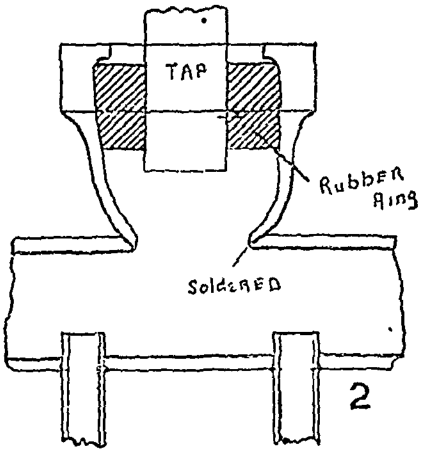
SEVERAL USEFUL LABORATORY DEVICES

MARTIN E. REHFUSS, M.D.
PHILADELPHIA

Rapidity in laboratory technic depends to a great extent on the simplicity and efficiency of the apparatus; a minimum of time and inconvenience being always an important factor in any method. The following two pieces of apparatus are exceedingly simple and are recommended for their comparative inexpensiveness as well as their general efficiency. They were devised to fill a need in certain work, and were so satisfactory that I have taken the liberty to report them.

The first is a method for multiplying the water connection in order that a large number of tissues may be washed from a single tap. For instance, in a laboratory where only a few taps are available, unless some multiplying device is employed, it becomes almost impossible to wash a series of tissues satisfactorily at one time. The result is overfixation with all its attendant evils, a circumstance occurring only too frequently in microscopic work. In carrying tissues through a large number of fixatives the need for such a device is equally apparent. The device (Fig. 1) fulfills all indications. It consists of ¾ inch bore brass tube about 12 inches long, closed at each end by brass plugs finished flush with the surface. Below on the tube, holes were drilled 1¼ inches apart. Into these holes brass tubing of 3/16 inch bore and 1¼ inches in length are inserted and firmly soldered in place. Directly opposite and in the center of tube A the connection C is attached. It consists of an outer brass collar (see section, Fig. 2) with an inner rubber ring or washer by which the multiplier can be attached to the tap. It is essentially the same as the connection found on filters, except that the filter connection is cut in half and the upper portion soldered to the tube into which a hole of corresponding size is drilled. The device may then be nickel plated and makes an excellent piece of apparatus. Dr. Allen J. Smith suggested that the ends of the small tubes B be made bulbous, so that rubber tubing may be firmly tied on and then closed with a clamp when not in use, or instead of that, the use of stop cocks in place of tubes B.





Figs. 1 and 2.—Device for multiplying water connection and longitudinal section of same.

A more convenient and elaborate modification of the above may be made as in Figure 3. In this form both A and C are cast in one piece, and the tube A is closed at the ends by milled screws, which can be removed to facilitate cleaning of the instrument. Through the holes drilled in tube A a number of brass stop cocks can be screwed—each cock possessing a flange below for the purpose of holding the rubber tubing as mentioned above. This apparatus gives perfect control over the distribution of the water supply.

Either form of device is merely inserted on the tap and may be removed or applied instantly. Bottles covered with gauze can be connected directly with tubes B, or rubber tubes may be attached to the latter to lead anywhere. With even slight pressure no difficulty is experienced in making the water emerge from all the tubes at once. An apparatus of this kind has been used in the histologic laboratory of the University of Pennsylvania and has given entire satisfaction.

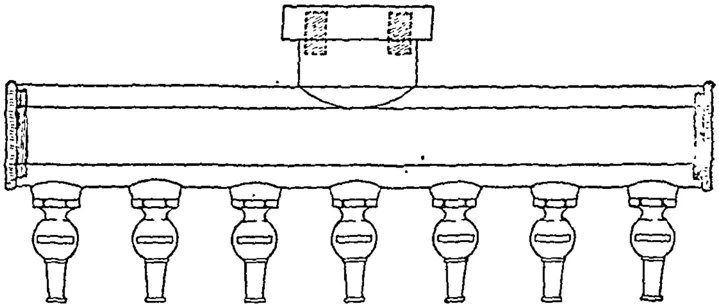


Fig. 3.—Another form of above device.

The next apparatus is a simple device for staining a large number of cover glasses at one time. Any one who has stained a series of one hundred or two hundred cover glasses knows how time-consuming such a procedure is. Having tried wire holders, perforated plates, etc., I have found none so convenient or so easily handled as the following (Figs. 4, 5 and 6): two metal (bronze or brass) strips (B) ⅝x2½x⅛ inches, connected by the middle bar (C) ¾ inch in length, are soldered together. Each metal strip has a number of parallel grooves 1/16 inch wide and 1/16 inch deep. Twenty such grooves are made in this instrument so that twenty cover glasses can be accommodated singly or forty back to back. Along the edge of each strip an extra strip of brass is soldered to act as a ledge (D). Then in the center of the connecting strip C a brass handle is screwed.

The above are the dimensions for an instrument which will take ⅞ inch or 22 mm. cover slips; of course, these can be modified to fit any sized cover glasses. In this way films, smears, or even sections may be carried through various solutions. Its advantages are:

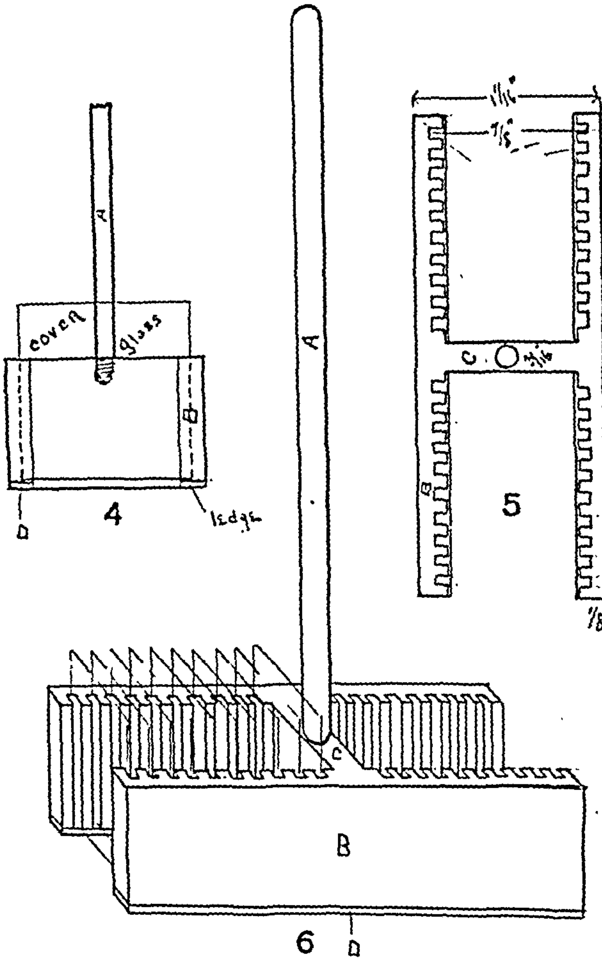
1. A uniform and complete covering of the cover glass is insured.

2. The metal strips B are ⅝ inch in height, allowing the ⅞ inch cover glasses to project ¼ inch, thus per-

mitting them to be more easily handled and manipulated.

3. Being 2½ inches long, it is easily introduced into a 3 inch reagent dish.

4. On the principle of the above any number of compartments can be made. By widening grooves and increasing the length of cross bar (C) the same instrument can be used to carry slides. Recently I have stained sections on cover glasses and find that the use of the above apparatus leaves nothing to be desired.



Figs. 4, 5 and 6.—Apparatus to be used in staining a number of sections at one time.

In using stains such as blood stains, it is well to determine beforehand the exact time necessary to stain and differentiate with a few single specimens in order that the entire series may be correct.

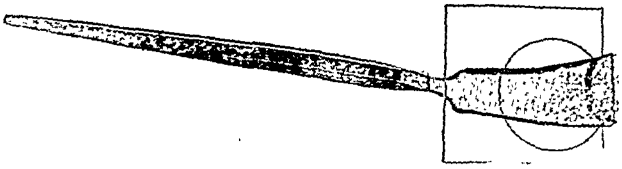


Fig. 7.—Section lifter bent in the form of a spring clamp for handling single specimens on cover slips.

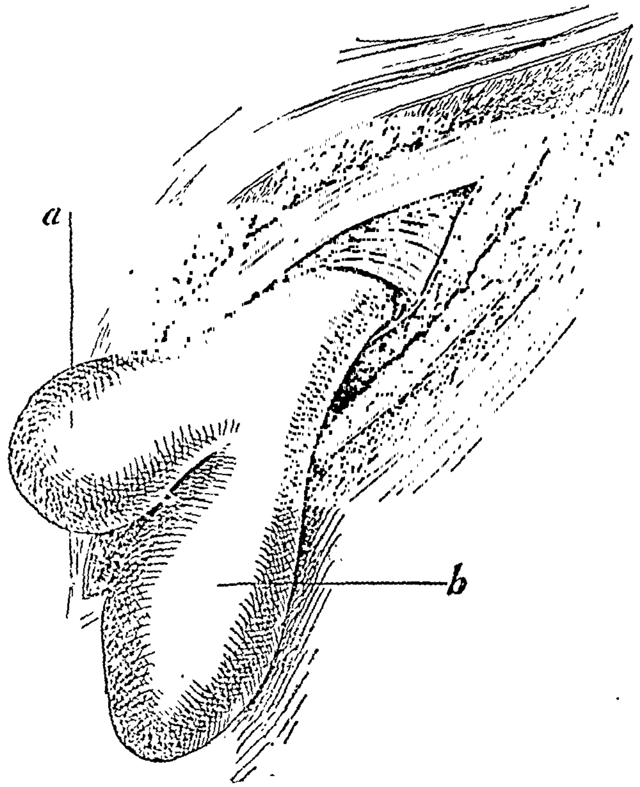
In manipulating single specimens on cover slips in various stains, etc., especially in small flat staining dishes where it is impossible to introduce the ordinary cover glass forceps, it is frequently of considerable service to turn up the edge of the section lifter (Fig. 7) so as to form a spring clamp, in which the cover glass may be inserted. This gives good control over the specimen and will serve many useful purposes.

1417 South Broad Street.

RARE VARIETY OF HERNIAL SAC

DANIEL N. EISENDRATH, M.D.
CHICAGO

The accompanying illustration shows a variety of hernial sac, the existence of which is but little known, and which does not seem to be referred to in the textbooks and other literature. I have encountered this form of double or "pantaloon" sac four times in my last one hundred cases of inguinal hernia. It is a bifid sac, the two limbs having a common sac where they unite, close to the internal ring. In some cases, the two sacs (a and b) are of almost equal length, resembling a man's trousers, so the name "pantaloon" seems to describe the anatomic condition accurately. I do not know by whom the term "pantaloon sac" was first employed to designate this double sac. In other cases the second sac is a mere diverticulum which leaves the main sac close to its neck and is usually so covered with fat as to be mistaken for a subserous lipoma. No doubt many recurrences following inguinal herniotomy are due to the fact that a diverticulum or second sac has been overlooked. My present practice is to separate the sac from the spermatic cord as high up as possible and to insert the finger into the sac to determine the presence or absence of diverticular sacs before proceeding to ligate the neck of the hernial sac, close to the internal ring.



Pantaloon or double hernial sac; a, secondary sac often covered by fat; b, main sac.

103 State Street.

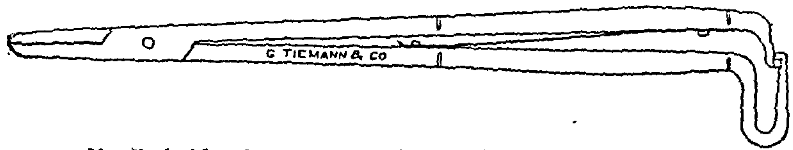
Diagnosis of Chronic Pancreatitis.—No single symptom can alone be relied on as diagnostic of chronic pancreatitis, but on considering all the available evidence there is not usually much difficulty in forming an opinion. Special stress can be laid on the progressive wasting, the usual presence of jaundice, the dyspeptic disturbances, the pancreatic reaction in the urine, and the results of the chemical examination of the urine and feces.—A. W. Mayo Robson, in *Annals of Medical Practice*.

AN IMPROVED NEEDLE-HOLDER

B. F. JENNESS, M.D.
Passed Assistant Surgeon, U. S. Navy, Assigned to the U. S. Naval Hospital
PUGET SOUND, WASH.

This instrument was devised to facilitate the suture operation for hemorrhoids, and to accompany the hemorrhoidal clamp, a description of which was published in 1909.*

The object of the design is to do away with the width of handle seen in other holders, which obstructs the view when working in deep or small cavities. The instrument illustrated measures 13/16 of an inch at the widest point on the handle. With the drop ratchet, which is below the level of the shank, forming a pistol grip, the instrument can be grasped in such a manner as to leave an unobstructed view of the needle along the upper surface of the handle and shank. The instrument is particularly adapted to rectal, vaginal and deep abdominal work. The length over all is 8½ inches. The rachet, which is dropped at right angles to the handle, measures 1¾ inches.



Needle-holder for rectal, vaginal and deep abdominal work.

NOTE ON STROPHANTHIN

ROBERT A. HATCHER, M.D.
Professor of Pharmacology in Cornell University Medical School;
Member of the Council on Pharmacy and Chemistry
of the American Medical Association
NEW YORK

It has been my intention for some time past to discuss the literature of strophanthin exhaustively. I have not yet been able to perform this task, but certain conditions have arisen which, unless counteracted by a word of warning, will entail accidents, thereby bringing this drug into disrepute at the very time when it gives the greatest promise of usefulness.

I have stated[1] that the tincture of strophanthus generally sold in the United States is of fairly uniform potency, and that the strophanthin of Merck and that of Boehringer and Sons are of practically the same activity, being about half as active as the crystalline ouabain, or so-called crystalline strophanthin of Thoms made by Merck.[2]

We have examined many specimens of strophanthus seed and tincture of strophanthus in the laboratory of the Department of Pharmacology and Materia Medica of Cornell University Medical College during the past three years, and have found them to be practically uniform in potency; but the government now excludes *Strophanthus hispidus*, admitting only the *Strophanthus kombé*, and we have found a specimen of the *Strophanthus kombé* just half as active as the *Strophanthus hispidus*. Recently we obtained a specimen of tincture of strophanthus from Bellevue Hospital which was also just half as active as those tinctures previously examined. This tincture was being used in the hospital without the slightest suspicion that it was not of exactly the same potency as that which had been used previously and which we had found to be twice as active as the later specimen.

The intravenous, as well as the intramuscular, use of strophanthin is based largely on the experience of Fraenkel,[3] who stated expressly that he used the amorphous strophanthin of Boehringer and Sons, the activity of this amorphous strophanthin being given as 15 frog units for each milligram of strophanthin. The frog unit conveys little idea to the mind of the average clinician, even if it were not true that various standards have been proposed for the frog unit, and if it were not also true that the therapeutic dose of strophanthus is not the same in frog units for strophanthus that it is for digitalis.

In this connection I wish to call attention again to the very simple and accurate standard which I have proposed for strophanthus preparations, viz., the cat unit, or that amount of strophanthin, or strophanthus, which is just fatal to 1 kg. of cat when it is slowly injected in about an hour and a half into the femoral vein.

Working with solutions of unknown strength we have repeatedly found that the limits of error do not exceed 5 per cent., and often they fall within 2 per cent.

Edmunds and Hale[4] have objected to this method on the ground that the action on the central nervous system cannot be excluded, but I have good reason for believing that this test is a far better index of the cardiac action on man than the frog test is.

Boehringer and Sons have put strophanthin on the market labeled "Strophanthin Boehringer for intravenous injections based on the investigations of Dr. Albert Fraenkel, Badenweiler. Twelve tubes, each containing 1 c.c. of sterilized 1/00 solution of strophanthin Boehringer."

The clinician might suppose that each tube actually contained just 1 c.c. of the solution, but several of these tubes were examined and found to contain 1.4, 1.2, and 1.4 c.c., respectively.

Hatcher and Bailey[5] reported that amorphous strophanthin was about half as active as the crystalline, and that the strophanthins of Merck and of Boehringer and Sons (amorphous) were of about equal potency.

This statement was based on a much larger number of experiments than had been performed by any other experimenter, so far as I am aware. Owing to the nature of the work, some of the tests had to be limited to a few animals, and with the greater precision of our present method we have found a slightly different ratio in some cases, and a greater difference in others. By subcutaneous injection, the amorphous strophanthin is, as stated, about half as active as the crystalline, but by intravenous injection some specimens at least approach the crystalline in toxicity for cats as will be seen by the accompanying table.

We have recently confirmed the statement made by Hatcher and Bailey[5] that the crystalline is twice as toxic as the amorphous for dogs by the vein.

It must be borne in mind that the amorphous strophanthin varies somewhat in activity, but so far we have found no variation in the activity of the crystalline.

[1] Hatcher, R. A.: Tincture of Strophanthus, THE JOURNAL A. M. A., 1907, xlviii, 1177.

[2] This crystalline strophanthin is not sold when Merck's strophanthin, or even Merck's crystalline strophanthin, is called for, since the official strophanthin is sometimes described as crystalline though it is really amorphous. The so-called crystalline strophanthin Thoms should be called crystalline ouabain.

[3] Fraenkel and Schwartz: Arch. exper. Path. u. Pharmakol., 1907, lvii, 79.

[4] Edmunds and Hale: Bull. 48, Hyg. Lab., U. S. P. H. and M.-H. S., 1908.

[5] Hatcher, R. A., and Bailey, H. C., Tincture of Strophanthus and Strophanthin, THE JOURNAL A. M. A., Jan. 2, 1909, lii, 5.

There is no apparent reason why this disadvantage of the amorphous, as well as of the tincture, may not be obviated by the use of a simple standard on which alone the therapeutic dose should be based.

Several accidents have been reported to me orally, following the subcutaneous injection of the tincture, and with the increasing use of strophanthin by the intramuscular and intravenous methods other accidents are very likely to occur unless care is taken to use only standardized preparations and to know the value of the standard employed.

The therapeutic dose of strophanthin by the vein should be approximately equal to five cat units; the daily dose by the mouth is probably about fifty cat units, though, as I have stated,[6] the use of strophanthus by the mouth is irrational in the present state of our knowledge concerning its absorption from the alimentary canal and its excretion and destruction in the body.

It has been stated that the oil contained in strophanthus seed is the cause of nausea, but we have found enormous doses of this oil to be without effect on cats; the emesis, on the other hand, results from the action of strophanthin on the medullary centers.

From the table it will be seen that the average therapeutic dose would be about 0.5 mg. (1/130 grain) of crystalline or amorphous strophanthin, or a little more of the latter, by vein; the intramuscular dose of the more active tincture should not exceed two minims daily.

It is a curious fact that, while the fatal dose of crystalline strophanthin by subcutaneous injection is only about 20 per cent. larger than the fatal intravenous dose for the cat, in the case of the amorphous more than twice as much is required by subcutaneous injection as by intravenous. Whether man shows the same difference or not we are unable to say. Intramuscular injections usually approach the intravenous in effectiveness.

Exophthalmic Goiter and Acute Articular Rheumatism.—Souques reports a case in which acute articular rheumatism was followed almost at once by development of symptoms of exophthalmic goiter. There was no history of alcoholism in the family. In two other cases acute articular rheumatism preceded the exophthalmic goiter in one case and in the other the mother and brother had had acute articular rheumatism. It is not long since Vincent found enlargement of the thyroid in two-thirds of all his cases of acute rheumatism, but it generally disappeared with it, leaving no traces. In other cases hyperfunctioning of the thyroid was evident in the tachycardia and nervous symptoms, and in 4 out of 6 such cases the exophthalmic goiter followed without transition; 3 similar cases have been reported by others. In a later series of 14 cases Vincent found a history of one or more attacks of acute articular rheumatism preceding the exophthalmic goiter. Souques' article was published in the *Bull. de la Soc. méd. des Hôp.*, 1910, xxvii, 26.

SCOPOLAMIN AND MORPHIN AS A PRELIMINARY TO GENERAL ANESTHESIA

A REPORT BASED ON AN EXPERIENCE OF ELEVEN HUNDRED CASES *

CLIFFORD U. COLLINS, M.D.
Surgeon to St. Francis Hospital
PEORIA, ILL.

To one who studies medical literature, the large number of articles on anesthesia seem to indicate that the ideal anesthetic has not been discovered or the ideal method of administration has not been invented. When anesthesia was first discovered, the only demand was that it relieve the patient of the knowledge of all pain during an operation. Additional demands have been made from time to time, however, until now the patient asks that he not only be relieved from the knowledge of pain, but that the anesthesia will be free from danger and discomfort to him. The surgeon insists that the anesthesia shall be free from danger and that the patient shall be quiet and passive, with the muscles relaxed, during the entire time of the operation.

Practically all the dangers can be avoided by an expert anesthetist in the judicious choice of the anesthetic and a skilful method of administration. This is evidenced by the reports of a large number of anesthesias given without a fatality in different parts of the country.[1, 2] Very much of the discomfort experienced by the patient while "going under" may be avoided by expertness on the part of the anesthetist, and a first-class anesthetist will give a smooth, uniform anesthesia that will keep the patient asleep and relaxed throughout the operation in response to the surgeon's requirements. These demands on the anesthetist are fast making the administration of anesthetics a special line of work, and the day seems not far distant when patients will insist that the anesthetist be trained and experienced in that particular part of the operative procedure.

With all the improvements in the choice of anesthetics and the method of their administration, there still remains with the patient a strong disinclination toward being put to sleep and passing through unknown dangers while utterly powerless to help himself in any way. This decided antipathy to being made unconscious amounts at times to a positive terror, and has been advanced as a cause of some of the sudden deaths reported under anesthesia. It was a desire to overcome this unpleasant feature that led me to use the combination of scopolamin and morphin as a preliminary to general anesthesia on myself at one time when I changed places and became, for the time being, patient instead of surgeon. The action of the preliminary was so satisfactory that I adopted its use in my work, and the following report, based on 1,120 cases in which it was used, is made so that the truth concerning this much abused combination may be ascertained.

My attention was first called to the use of the combination of 1/100 grain of scopolamin and 1/6 grain of morphin as a preliminary to a general anesthetic by an article by Dr. M. G. Seelig.[3] Since then, the combination has occupied a prominent place in the literature on anesthesia and much has been written for and against its use. My experience seems to prove that some of the things written are erroneous. Much of the misinformation has come from a failure to differentiate the use of the combination as a general anesthetic, in which a large dose is given, from its use as a preliminary to some other general anesthetic, in which the dose is comparatively small. The experience related in this article is based on its use as a preliminary. As many things have been written that are contrary to my experience, a brief reference to some of them may not be out of place.

---

[6] Hatcher, R. A., Am. Jour. Physiol., 1909, xxiii, 304.

* Read before the Western Surgical and Gynecological Association at Omaha, Dec. 21, 1909.

1. Magaw, Alice: A Review of Over Fourteen Thousand Surgical Anesthesias. Surg., Gynec. and Obst., December, 1906, p. 795.

2. Teter, C. K.: Thirteen Thousand Administrations of Nitrous Oxide and Oxygen as an Anesthetic, THE JOURNAL A. M. A., Aug. 7, 1909, p. 448.

3. Seelig, M. G.: Scopolamin-Morphin as an Adjuvant in the Administration of General Anesthesia, Ann. Surg., August, 1905, p. 185.

In 1905 Dr. Felix Terrier,[4] of Paris, wrote in relation to the scopolamin and morphin combination: "It should be noted that when we wish or are obliged to employ another anesthetic, as well, we must never use ether, but always chloroform." In another place he says again: "We call attention once more to the fact that scopolamin should never be combined with ether, whose dangers it increases." In a large majority of the patients here referred to, the scopolamin-morphin combination was given as a preliminary to ether anesthesia, and no harmful effects were noticed.

In December, 1908, Dr. J. C. Bloodgood,[5] in abstracting a German article on the scopolamin and morphin combination, says: "It is contraindicated in exophthalmic goiter." I use more of the combination in exophthalmic goiter cases, because, in the effort to "steal the gland," as Crile recommends, I give a dose the night before in addition to the dose given preliminary to the general anesthetic. I have seen no harmful results in the exophthalmic goiter cases. In the same abstract Dr. Bloodgood says: "It is difficult, however, in an active clinic to know in all cases when the hour before the operation will be." This is true, but it can be managed. I have frequently had a series of eight and ten cases on an operating morning, and each patient had the preliminary dose of scopolamin and morphin at approximately the proper time.

It has been urged that the scopolamin and morphin combination produces a contraction of the abdominal muscles that makes operating more difficult. I have not found this to be true. I have noticed, however, that it is difficult sometimes for the anesthetist to tell just when the patient is properly under the general anesthetic. He lies so quietly under the influence of the scopolamin and morphin that the anesthetist is apt to think that he is ready and properly relaxed when he is not. In those cases some contraction of the abdominal muscles will be noticed. A little more of the general anesthetic quickly remedies it.

In reply to the question of a correspondent The Journal of the American Medical Association[6] says: "It [referring to scopolamin] is used for local anesthesia in connection with morphin." I have never seen any local anesthetic effects produced by the combination and have not heard of it being used in that way. Dr. H. C. Wood, Jr.,[7] of Philadelphia, condemns the use of the combination strongly as a preliminary, although giving no personal experience on which to base his disapproval of its use.

The foregoing extracts are quoted to show what a large amount of misinformation has crept into the literature. On the other hand, since Dr. Seelig's report of sixty-five cases in 1905, other reports are coming in telling of the beneficent effects of this combination when used as a preliminary to general anesthesia, and these reports are based on a large experience. Dr. C. M. Nicholson[8] reported to this association, at its last meeting, 650 cases in which the combination had been used with no unfavorable results. He also reported the results of experiments on animals which seemed to contradict the conclusions of Whitacre,[9] who claimed that the scopolamin-morphin combination produced fatty degeneration of the kidneys and liver when injected into animals.

It looks very much as if the prophecy made by Dr. James Taylor Gwathmey[10] was coming true. He said: "But the administration of grain 1/100 scopolamin and grain 1/6 morphin one-half hour before the operation and supplementing this by as much of any general pulmonary anesthetic as may be necessary is theoretically correct and clinically safe. . . . The combination of scopolamin and morphin or chloretone or cocain locally, plus a small amount of some pulmonary anesthetic, will undoubtedly be the anesthetic of the future." My experience corroborates fully the experience of Dr. Gwathmey as related in the article from which the above was quoted.

TECHNIC OF ADMINISTRATION

Tablets are obtained containing a combination of scopolamin, 1/100 grain, and morphin, 1/6 grain, and the solution is made just before it is administered hypodermically, which is done one and one-half hours before the operation is begun. Relatives or friends are not allowed to see the patient after the hypodermic has been given. Sometimes an exception is made in the case of a husband and wife, but imperative instructions are given that the patient is not to be talked to and roused.

All necessary manipulations and handling of the patient in the preparation are completed before the hypodermic is administered. The room is darkened and everything kept quiet, and he falls into a tranquil slumber. About twenty minutes before the operation a layer of damp cotton is placed over the eyes and the patient is taken to the operating room and placed on the operating table. The preliminary cleansing of the skin over the site of the operation is gently done while the general anesthetic is being administered. The preparation and the anesthetization are usually completed about the same time and the operation proceeds.

The preliminary hypodermic injection of the combination is given to all patients from eight years of age up. If an elderly patient is considered strong enough to undergo an operation, he is considered strong enough to have the beneficial effects of the combination and it has not been withheld from any elderly patient on account of his age. Children are more apt to be nervous and apprehensive immediately prior to the operation than adults; therefore the preliminary is given to all children who are eight years old and older. There is a strong nervous factor in exophthalmic goiter cases, and it has been claimed that nervous excitement increases the secretion of the gland which is already overactive. For this reason I give the preliminary the night before the operation in these cases and again one and one-half hours before.

I have not found any contraindication to the combination. If a patient's condition is sufficiently good to make an operation justifiable it is sufficiently good to permit the use of the preliminary injection of scopolamin and morphin. Very ill patients do better when very little general anesthetic is given them, and the preliminary of scopolamin and morphin permits the minimum amount of the general anesthetic to produce the desired amount of anesthesia.

When I first began to use the combination I used some chloroform as a general anesthetic, but I quit using chloroform after a time and began using ether almost exclusively. In the majority of the cases embodied in this report the combination was used as a preliminary to ether as a general anesthetic. Lately I have been using nitrous-oxid gas to a considerable extent and find that the scopolamin and morphin combination acts equally well as a preliminary to that general anesthetic. There is a great deal less of the convulsive movement of the muscles as the patient is going under the influence of the gas when the preliminary is used.

I used the much advertised hyoscin-morphin-cactin combination in about seventy cases, but could see no advantage in its use and went back to the scopolamin and morphin. I used the morphin and atropin combination in a few cases, but could see no reason for continuing its use when the scopolamin and morphin combination will do all that the morphin and atropin combination will do and give, in addition, the added hypnotic influence of the scopolamin.

There have been no deaths that could be in any way attributed to the preliminary use of scopolamin and morphin. There were unpleasant symptoms in only one case. In 1907, among the early cases reported in this series, one patient had some symptoms which seemed dangerous at the time. The patient was a woman, aged 23, and the following is the record of the case:

> She was given the usual dose of scopolamin and morphin at 2:30 p. m. and the operation was started at 4 p. m. She came into the operating room drowsy and in the usual condition after the preliminary injection of scopolamin and morphin. The appendix was removed and the uterus suspended. The length of the operation was twenty-four minutes. She was put to bed and normal salt solution given by rectum with the foot of the bed elevated. At 5:45 p. m. the nurse found her face blue and that she was breathing very slowly. It looked to the sister in charge as if the respirations had almost stopped. The sister pulled out the tongue with forceps, performed artificial respiration, and dilated the rectum. I saw the patient at 6:15 p. m. Her face was then a reddish blue, the pupils partially contracted and insensible to light, respirations 8 to the minute and a full pulse 96 to the minute. I ordered an enema of hot coffee which was given. In fifteen minutes the woman began to improve and at 7:15 p. m. she was breathing naturally, her face was a normal color, and she was talking and complaining of feeling thirsty. The general condition and symptoms seemed to be that of morphin poisoning. It was surprising that the bad symptoms came on so late, more than three hours after the preliminary injection. Her further recovery was uneventful.

Either the patient had an idiosyncrasy for one of the drugs, or the tablets did not contain a uniform dosage and the tablet given her contained more than the usual dose. I am inclined to the latter explanation because I have seen no bad effects since. For the past year the anesthetizers have noticed a more uniform effect of the combination on the patients and we are inclined to attribute it to a better tablet with a correct dose.

About thirty minutes after receiving the hypodermic the patient becomes drowsy and is an eligible candidate for the "Don't Worry Club." All apprehension and fear regarding the operation is gone. He can be easily aroused, but should not be disturbed. He is partially asleep when taken to the operating room and in a tranquil condition of mind. The transition from a partial sleep to complete anesthesia is not so sudden as from complete wakefulness to complete anesthesia and is easily accomplished. A much less quantity of the general anesthetic is required to keep him completely anesthetized. After the operation he usually sleeps from three to five hours, and may partially awake and go to sleep again two or three times before becoming completely awake. The sleep after the operation saves him from the smarting pain of the recently incised skin and injured tissues.

There is much less postoperative vomiting, about nine patients out of ten having practically none at all. The secretion of mucus in the throat is markedly checked and in most of the cases is completely stopped. This prevents the danger of aspirating mucus into the respiratory passages and makes a quiet anesthesia.

The above experience based on eleven hundred cases seems to show that scopolamin and morphin as a preliminary to general anesthesia is a rational procedure, adding greatly to the comfort of the patient by relieving him of all nervous apprehension prior to the administration of the general anesthetic, by permitting him to sleep some hours after the operation is completed, and by greatly decreasing the postoperative vomiting, and mitigating the dangers of the general anesthetic by lessening the amount necessary to produce the desired effect and by checking the secretion of mucus in the throat.

A CASE OF SYPHILIS OF THE LIVER, PROBABLY LATE CONGENITAL SYPHILIS *

WILLIAM FITCH CHENEY, M.D.
Professor of Principles and Practice of Medicine, Cooper Medical College; Physician to Lane Hospital
SAN FRANCISCO

The art of diagnosis has not yet become so easy that it has altogether lost its charm, and now and then we meet a problem that, like the plot of a well-constructed novel, baffles solution until the last chapter. Such a diagnostic problem was the one about to be recorded, and, though its solution seems to have been satisfactorily reached, the fact remains that the last chapter has not yet been read and a degree of uncertainty must, therefore, still exist.

Patient.—There came to the clinic of Cooper Medical College last September (1909) a young man aged 18 who complained of a swollen abdomen. Cursory examination showed that he had an ascites and he was therefore sent to the ward in Lane Hospital for further investigation. As his case proved to be an unusual one, where every scrap of available evidence was essential, his history will be given in detail, so far as we were able to obtain it.

Family History.—The father had been drowned at sea some years before; he had no disease at the time so far as known. The mother was living and in fair health; she had had but one miscarriage; and this subsequent to the birth of this patient; she said her hair had fallen out at the time of the birth of this child and subsequently; she had had no ulcers or soreness of the nipples while nursing him; recently she had had some slight pulmonary symptoms—cough and expectoration. There were three sisters living and well, no children dead. There had never been any disease in the family similar to his own.

---

* Read before the Cooper College Science Club, Jan. 10, 1910.

Past History.—The boy had whooping cough and mumps in childhood, but no measles, scarlet fever or diphtheria. At 8 years of age he had a prolonged cough, but with no blood in the sputum. He never had typhoid, pneumonia or malaria. He never had gonorrhea or a venereal sore, and denied all exposure. There had been no skin eruption at any time, and no sore throat. He took a couple of glasses of beer each evening but no other alcoholic drink. He did not use tobacco in any form. He worked as a boiler maker and his habits of life were regular.

Recent History.—Six months previous to coming to the clinic he had been operated on for inguinal hernia. Following that operation he developed pleurisy on both sides, with considerable pain but not enough fluid to require aspiration. He apparently recovered from that entirely and remained well and at work for several months afterward.

Present Illness.—About three weeks before presenting himself at the clinic he noticed that his abdomen began to swell. At that time he had been eating freely of fruit and drinking large quantities of water, to which he attributed the swelling. He had no pain at all in the abdomen when the swelling began, and only slight pain at times since then. His bowels had been constipated rather than loose. There had been no vomiting or disturbance of digestion. He had no cough and no pain in the chest; but felt that he had fever each afternoon, and every night recently he had a sweat. He did not think he had lost in weight, but felt weak and unable to work.

Physical Examination.—The patient was poorly developed, moderately emaciated, pale and slightly icteric. Ears appeared normal; eyes showed no corneal scars, pupils reacted equally; nose was normal in contour; mouth showed teeth in good condition, tongue slightly coated on dorsum and bright red along sides. Throat showed no ulcerations, plaques, unusual redness, nor tonsil hypertrophy. Cervical glands were not enlarged.

Chest.—Clavicles were prominent, musculature poor, ribs all plainly visible; expansion limited. On percussion, with patient lying on the back, on the right side dulness began at the fourth rib, and traced downward was continuous over the base of the lung with that of the liver below; on the left side dulness began at the level of the nipple and was continuous downward for 19 cm. in the anterior axillary line. Examining the back with patient erect, dulness was found over the right base as high as the fifth dorsal spine and over the left as high as the seventh. Below the line of dulness vocal fremitus was everywhere absent. The breath sounds over both upper lobes, front and back, were loud and free from râles but harsh and bronchovesicular; below the line of dulness they gradually diminished and then disappeared entirely.

Heart.—The cardiac impulse lay high in the chest, visible in the second, third and fourth left intercostal spaces, with the maximum in the fourth space 4 cm. internal to the nipple line. The area of cardiac dulness merged with that over the lungs. The heart sounds were all clear except for a soft systolic murmur over the pulmonic area.

Abdomen.—On inspection this was symmetrically distended; over its surface and that of the lower thorax many dilated veins were visible; in the left inguinal region was the scar of the old hernia operation. Palpation gave a distinct fluctuation wave across the abdomen; in the upper abdomen, on the right side a hard, smooth, rounded mass could be felt on deep inspiration, resembling the lower border of the liver; on the left side on deep inspiration, the edge of the spleen could easily be made out below the costal margin; but no other masses could be palpated elsewhere in the abdomen, and there were no enlarged inguinal glands. On percussion the liver dulness extended 6 cm. below the costal margin in the nipple line; dulness was found in each flank and in the lower abdomen with the patient on the back, rising 4 cm. higher toward the navel, as the patient sat erect; over the rest of the abdomen the percussion note was tympanitic.

Genitalia.—The penis showed no scar; there was no edema of the scrotum; no palpable masses were found in the testicles.

Lower Extremities.—These were poorly developed and emaciated, but showed no scars nor irregularities along the tibiæ; there was no swelling of the ankles or feet; the patellar and plantar reflexes were intact and there was no disturbance of sensation.

I. EVIDENCE FOR TUBERCULOSIS

With such a history and status the first thought was of tuberculosis as a cause. The evidence in favor of this explanation was as follows:

1. *The History of Onset.*—A young man previously in good health had a fibrinous pleurisy involving both sides of his chest; this subsided, but a few months later he developed insidiously and without pain an enlargement of his abdomen; such a story certainly created a strong suspicion of tubercular pleura and peritoneum.

2. *The Physical Findings.*—The patient had an ascites; there was no disease of heart or kidneys to account for it; there was no dropsy elsewhere except in both pleural cavities; and coincident fluid in abdomen and pleura has long been looked on as a clinical combination suggesting tuberculosis. Speaking of ascites in the diagnosis of tuberculous peritonitis, Osler says: "A most important point is the simultaneous presence of a pleurisy." The dilated veins in the abdominal wall were interpreted to mean portal obstruction; and this was explained by the supposition of enlarged tubercular glands compressing the vein at the portal fissure. Cirrhosis of the liver as a cause of the ascites and of the portal obstruction was improbable in the light of the previous history and did not explain the coincident pleuritic effusion.

3. *The Temperature.*—The patient was found to have a remittent type of fever, normal each morning, 101 or 101.5 each evening; characteristic of chronic tuberculosis of serous membranes.

II. EVIDENCE AGAINST TUBERCULOSIS

But in spite of these clinical data speaking for tuberculosis, there were other findings that did not fit such an explanation of the case. These were as follows:

1. *The Absence of Tuberculin Reactions.*—The first of these to be tried was the Calmette ocular tuberculin test; it was entirely negative. Later the Moro cutaneous test was employed, likewise without the slightest reaction. The von Pirquet test was not used, because it was realized that even if a reaction was obtained it might be due to sensitization caused by the previous tests. Tuberculin subcutaneously was contraindicated by the patient's daily evening temperature.

2. *The Character of the Ascitic Fluid.*—This was found to be clear, amber yellow, alkaline, specific gravity 1010, with a moderate amount of coagulum on heating; and the centrifugalized sediment showing microscopically a few red blood corpuscles, but no polymorphonuclear leucocytes, no lymphocytes, no cellular masses and no tubercle bacilli. Such a finding was not the one expected in tubercular peritonitis, corresponding rather to a transudate from portal obstruction than to an exudate from chronic inflammation.

3. *The Character of the Pleuritic Fluid.*—This was likewise a clear amber fluid; it showed microscopically many red blood corpuscles, numerous leucocytes with relatively many lymphocytes, a moderate number of endothelial cells, but no tubercle bacilli and no other micro-organisms. A guinea-pig injected intraperitoneally with this fluid and killed after one month showed no lesions of tuberculosis.

4. *The Blood Examination.*—This showed the hemoglobin, 58 per cent.; red corpuscles, 5,064,000; white corpuscles, 13,400; polymorphonuclears 80 per cent.,

large lymphocytes 11 per cent., small lymphocytes 8 per cent., eosinophiles 1 per cent. The normal number of red cells found was attributed to the concentration of the blood caused by the withdrawal of water into the pleural and abdominal cavities; for such a result is common with any large exudate or transudate. The low hemoglobin percentage showed, however, that in reality a considerable anemia was present. The leucocytosis found, though moderate, was the point particularly against tuberculous peritonitis: for in the latter condition the white count is usually either normal or subnormal; and tuberculosis in general does not cause leucocytosis, excepting when a secondary infection has occurred.

5. *The Findings at Exploratory Operation.*—Dock[1] makes a plea for laparotomy rather than paracentesis in ascites. When the cause of the ascites is obscure and other means of diagnosis have failed to determine it, there is no doubt that the plan urged by Dock is a wise one. I have employed it a number of times since Dock's article appeared and always with satisfaction. In this particular case exploratory laparotomy was done by Dr. Stanley Stillman and gave the clue to ultimate diagnosis. It showed no miliary tubercles scattered over parietal or visceral peritoneum, such as one expects to find in tuberculous peritonitis; and no enlarged glands in the mesentery or in the portal fissure; in other words, the findings were not those of tuberculosis. What was found spoke rather for syphilis of the liver as a cause of the ascites—a diagnosis that previously had no evidence whatever to make it worthy of consideration.

III. EVIDENCE FOR SYPHILIS

1. *The Findings at Exploratory Operation.*—The liver was found enlarged, its capsule thickened, its tissue hardened; and scattered through all parts of its substance were numerous nodules varying in size from a pea to a walnut, such as one sees in syphilitic gumma or in malignant disease of the liver. The spleen was visibly and palpably enlarged, its capsule thickened, its substance firmer and harder than normal. No other abnormality of abdominal organs was found on gross inspection.

2. *The Findings on Tissue Examination.*—At the time of operation a portion of the liver substance extending from the superior surface down through a nodule was excised for microscopic examination. The following report was rendered by the pathologist, Dr. William Ophuls, to whom the specimen was submitted:

> Sections show very marked increase in the periportal connective tissue, in some places being so marked as to practically obliterate the liver lobules; there is marked cellular infiltration; one section shows a large caseous area, surrounded by dense fibrous tissue; there are some epithelioid cells but no giant cells; no definite tubercles made out; no tubercle bacilli found. Diagnosis: Syphiloma of liver with marked cirrhosis of liver.

3. *Positive Wassermann Reaction.*—Subsequent to the findings at operation, the Wassermann test was made by Dr. H. R. Oliver. A positive reaction was obtained with blood drawn from the arm, and later was again obtained with the ascitic fluid.

4. *Effects of Treatment.*—As soon as the diagnosis of syphilis seemed fairly established the patient was at once placed on specific treatment, which has been continued ever since. He slowly but gradually improved and is now in better health than he has been for months previous. His pleuritic fluid has entirely disappeared from both sides; and his ascites is so small in amount that it gives him no annoyance and is steadily growing less.

IV. EVIDENCE AGAINST SYPHILIS

1. *Absence of History.*—While but little reliance can be placed on a patient's statements regarding venereal disease, nevertheless the testimony on this point cannot be entirely ignored. This boy not only denied ever having had a sore on his penis, but also ever having had sexual intercourse. Furthermore, carefully questioned, he had no history of the symptoms of early syphilis: no skin eruptions, no sore throat or mouth, no enlarged glands.

2. *Absence of Other Lesions.*—Syphilis of the liver is a late manifestation; before it occurs others have preceded and many of these leave their marks behind them. Over this boy's body there were no enlarged glands found; none of the round, depressed scars over the skin of the legs, so characteristic of destructive syphilitic skin lesions; no irregularities along the crests of the tibiæ; no deformity of the palate or fauces or tongue or nose; and, finally, no scar on the penis.

3. *The Improbability of Syphilis of the Liver.*—In the first place, tertiary syphilis of the liver is comparatively rare and, therefore, not to be accepted as a diagnosis without abundant proof. Keyes[2] quotes Fournier as saying that he found liver syphilis only 9 times among 4,400 tertiary lesions. Rolleston[3] says that in 11,629 autopsies at St. George's Hospital during a period of forty-two years only 37 cases of hepatic gumma were found and 27 cases of hepatic cicatrices. Flexner,[4] in reviewing 5,088 autopsies at the Philadelphia Hospital during thirty-five years, found that hepatic gumma were present in only 23 cases, hepatic cicatrices in 38, and in all there were only 88 cases of hepatic syphilis. In the second place, syphilis of the liver is a late manifestation, one of the so-called tertiary lesions. This means that the primary infection must have occurred at least five years, and more likely ten or even twenty years, before the hepatic manifestation. As this patient was only 18 when he came under observation, the improbability of liver syphilis was manifest and led in the early investigation to the rejection of such a diagnosis.

Nevertheless, in spite of the absence of history, of marks of the disease and of the improbability of syphilis, the findings at the exploratory operation and at the tissue examination, taken in connection with the positive Wassermann reaction, compelled a revision of diagnosis. All of the clinical evidence was against acquired syphilis, yet the pathologist and the laboratory worker found conclusive evidence that syphilis was present; the only possible explanation remaining was that the case was one of late congenital syphilis. A review of the evidence for and against this diagnosis was therefore made.

V. EVIDENCE FOR LATE CONGENITAL SYPHILIS

1. *Frequency of Hepatic Lesions in Congenital Syphilis.*—The liver is found to be affected in a high proportion of cases of congenital syphilis, according to all authorities, contrasting strongly with acquired syphilis, where hepatic lesions are so rare. This is true not only

[4] New York Med. Jour., 1902, p. 101.

in infants dying of the disease, but in the cases of late congenital syphilis, occurring anywhere in the first, second or third decades of life. In 1902 Forbes[5] collected 132 cases showing the lesions of late congenital syphilis in one form or another, and in 34 per cent. of these the liver was affected.

2. *The Clinical Findings.*—The clinical features described as occurring in late congenital syphilis of the liver are those found in this case—enlargement of liver and spleen, with ascites as a very common manifestation.

3. *The Mother's Condition.*—After a diagnosis of late congenital syphilis had been reached, it seemed wise to investigate the surviving parent for proof as to whether the disease existed there. A test of the mother's blood by means of the Wassermann technic was, therefore, made for us by Dr. H. R. Oliver and the blood showed a positive reaction.

VI. EVIDENCE AGAINST LATE CONGENITAL SYPHILIS

In the face of all the facts so far presented the diagnosis seems fairly certain; and yet there are missing links in the chain of evidence, whose absence cannot be overlooked.

1. *Absence of Stigmata.*—These are the so-called stigmata of congenital syphilis, such as the Hutchinson's teeth; interstitial keratitis or its scars; deafness; bone deformities, such as asymmetry of the skull, saddle nose, saber tibia; and constitutional marks, such as physical and mental backwardness of development, amounting to infantilism or even idiocy. Not one of these stigmata could be found present in this case. The absence of these is at least very unusual and cannot fail to cast doubt on the situation.

There is, however, one remaining possibility not yet mentioned—an early acquired syphilis—acquired by some other than the venereal route. On this point of stigmata Rolleston says:

> In order to be sure that the case is one of delayed congenital syphilis there must be some other evidence of congenital syphilis, such as interstitial keratitis, otherwise the disease might have been acquired in early life; for example, from a wet nurse.

And again in another place he says:

> The diagnosis rests on the evidence of congenital syphilis, as shown by interstitial keratitis, Hutchinson's teeth, deafness and infantilism, together with hepatic enlargement. If evidence of syphilis common to the congenital and the acquired forms, such as gummata are present and none of the stigmata of the congenital variety are obvious, the infection may have been acquired in early life.

Finally, no explanation of this case so far offered accounts for the double pleuritic effusion, which is not a common feature either of late congenital syphilis or of tertiary acquired syphilis. The only supposition possible seems to be that of a coincident gummatous condition existing in both pulmonary bases as well as in the liver, perhaps having gained access by extension through the diaphragm. But this must remain a theory until such time as the last chapter in our fascinating problem lies open before us—a chapter which as clinicians we are bound to postpone as long as we possibly can.

FATAL LEAD POISONING FROM THE USE OF BUROW'S SOLUTION

WILLIAM S. GOTTHEIL, M.D.
NEW YORK

Several years ago the following case of lead poisoning with fatal termination occurred in one of my hospital services. For obvious reasons its publication has been delayed.

History.—A young man was admitted to hospital suffering from an electric burn received a month before. A cold chisel had fallen out of his hand onto the third rail of the electric railway where he was working, and the resulting flash had burned both hands and his face, neck and the upper chest (it being summer his shirt was open), but had not set his clothing on fire. There was moderately extensive burn of the face, neck and chest, much of it eroded and with some necrotic areas. His left hand showed on the dorsum merely a large raw area; but the right, in addition to the second degree burn that covered most of the surface, showed beginning necrosis of the last phalanx of the thumb and of the tips of the middle and index fingers; and the extensor ossis metacarpi pollicis was exposed, as also was one tendon on the anterior surface of the forearm. In spite of his severe lesions, the patient's general condition was not bad; the temperature rose only a degree in the evening, the kidney functions were perfect, the gastrointestinal tract was in good condition and the appetite was good. The chest and abdomen were negative. The erythema of the more lightly burned areas was passing off; granulation was beginning; but there were still some necrotic masses. He had been under medical care, but it was impossible to ascertain what had been used, save that it was a moist dressing.

Treatment of the Burns.—Of general treatment the patient required hardly anything; the local treatment given was wet dressings of Burow's solution of the usual formula (a mixture of aluminum acetate and lead sulphate), 1 to 8 parts of distilled water. The lesions did exceedingly well; the sloughs were cast off, granulation progressed, the exposed tendons began to be covered, and a line of demarcation appeared and deepened behind the necrosed finger tips.

Result.—The man's general condition, however, became unsatisfactory. After being some three weeks in the hospital constipation set in; the record shows almost daily administration of calomel, rhubarb and soda, etc. In the fourth week he began to complain of pain in the stomach, and examination revealed a point of epigastric tenderness; he vomited once or twice, voiding stomach contents only; his tongue was coated and his breath was foul. A gastric ulcer was suspected; but examination by the internist on duty revealed no positive evidence of it. One week later, the epigastric pain and vomiting having continued, and moderate emaciation having set in, the presence of slight tremor of the hands and a faint but appreciable blue line on the gums enabled the diagnosis of lead poisoning to be made.

Treatment of the Lead Poisoning.—The use of the Burow's solution was immediately stopped and replaced by 10 per cent. balsam of Peru in oil. Steady improvement in the local conditions continued; but the lead intoxication increased, in spite of all that could be done. Purgatives, magnesium sulphate, potassic iodid, and varied measures to promote the elimination of the poisonous metal and to sustain the patient's resistance did indeed relieve the epigastric pain and the vomiting, but the man's condition in general became steadily worse. Weakness became more marked; wrist drop appeared; and the patient became delirious at intervals. In the seventh week after his admission to the hospital he was continuously delirious, being so violent that he had to be restrained; ecchymoses appeared on backs of the hands and arms, and on the legs, and the tremors of the limbs, tongue, etc., became very marked. He died at the beginning of the eighth week.

Undoubtedly systemic lead poisoning occurred from absorption by the granulating wound surfaces. Though wet compresses of the dilute Burow's solution were used on the face, none were used around the mouth, as the lips had not been burnt; and, the hands being in an impervious (rubber tissue) outer dressing, the patient was fed, and there was little chance of any direct introduction of the metal as a contamination of the food. Besides, the intensity and severity of the intoxication is proof that the metal must have been introduced and absorbed in comparatively large quantities in a short time.

The entire time of application of the lead solution was five weeks. Symptoms of plumbism appeared at three weeks; they were severe by the fifth week; and the patient succumbed in the eighth week. It is not reasonable to suppose that the accidental absorption through the gastrointestinal tract of small quantities of the lead solution could be responsible for so acute and profound intoxication.

Examination of the ward solution used for the dressings when suspicion was directed to it showed a fairly abundant snow white deposit on the bottom of the jar, with a clear supernatant fluid. It was applied, according to the druggist's directions, after being well shaken. Investigation of the various formulas for the preparation of Burow's solution showed that they differed regarding the filtration of the mixture. Some direct this to be done, only the clear filtrate being used; while others omit it, saying the mixture is to be well shaken before application.

Lead salts in solution or suspension are generally recommended in many dermatoses, the supposition being that absorption does not occur, at all events when the epidermis is intact. Lewin[1] found that even the frequent, persistent and extensive use of a 10 per cent. lead acetate spray could not force the metal through the skin; though he did note absorption when there was inflammation or destruction of the corneous layer. Practically all authorities, from Cazenave and Schedel, in 1862, to Audry, Durand, and Nicolas, in 1909, recommend lead salts in solution, ointment, or plaster for various dermatoses, including inflammations and infections, and without any mention of danger of absorption. Nor is its use confined to affections in which the corneous layer is preserved. Crocker[2] uses subacetate of lead lotions in excoriations, and Paschkis[3] recommends lead water for erosions and ulcerations of all kinds, stating that when the epidermis has been destroyed the lead combines with the exudation and forms a protecting cover.

Furthermore, lead applications are advised in burns by many surgical and dermatologic authorities, and usually without any special reference to danger. Gross[4] and Wyeth[5] recommend ordinary white lead paint; Wood[6] uses carbonate of lead in linseed oil or as an ointment; Veiel[7] and Bum[8] employ lead lotions, and von Notthaft[9] and Theimenn[10] use lead water. Witherstine,[11] Ringer[12] and Wood,[6] while recommending the treatment, do refer to the possibilities of absorption if employed on large surfaces.

Liquor aluminii acetici crudus or Burow's solution, diluted, is so universally employed, especially in Germany, for the treatment of burn that quotation of authorities is unnecessary. There is, however, a radical difference in the formulas recommended, so that the preparation may be a clear solution of aluminum acetate or a turbid fluid containing an abundant precipitate of sulphate of lead.

Liquor aluminii acetici crudus, Burow's solution,[13] is made as follows: 95 parts of potassic alum are dissolved in 700 parts of distilled water, to which, when cooled, is added 151 parts of powdered "raw" lead acetate. This is filtered; 100 parts of the clear fluid contain 5 parts of *aluminium acetate, with a little potassic acetate.* No lead or other heavy metal is in the filtrate, as shown by the absence of precipitation on passing sulphuretted hydrogen through the fluid.[14] This is the formula of a number of authors; and von Notthaft[15] refers to liquor alumini acetici as a clear, colorless fluid containing from 7.5 to 8 per cent. of basic aluminum acetate without either precipitated lead sulphate or any excess of soluble lead acetate.

Nevertheless this same writer,[15] in giving the formula of Burow's solution, directs that 5 parts of crude alum and 25 parts of basic acetate of lead are to be dissolved in 500 parts of water, and then, saying nothing of filtration or decantation, adds the direction, "to be well shaken before using." This is proof positive that the precipitate is to be used. In this he is followed by a number of authorities, of whom I need mention only two as typical. Lang[16] expressly prefers von Notthaft's formula, using the freshly prepared solution as a wet dressing. Luithlen[17] rejects the new, i. e., filtration, methods for the preparation of Burow's solution, and states explicitly, "and the preparation is best used unfiltered, being well shaken before it is employed." Inquiry as to the practice in the medical institutions of this city reveals a similar difference. In some of them Burow's solution is always decanted or filtered or both before use; in others, including some of the largest, the sediment is carefully preserved as part of the lotion. The sediment, of course, is practically pure sulphate of lead.

In spite of the extensive use of lead in various forms as an external application, serious plumbism from this source seems to be very rare; hardly any cases reported. I have been able to find but two. J. O'Carroll[18] reports a fatal case from the use of a hair dye containing lead. Pässler[19] saw the use of diachylon ointment in an eczematous infant cause a violent attack of lead poisoning, with a hemorrhagic nephritis, but ending in recovery. Idiosyncrasy is evidently a factor of prime importance in these cases; and very probably milder and unreported cases of lead poisoning through the integument are not so rare. Since the occurrence of the case here reported I no longer use Burow's solution, filtered or unfiltered, for cases of burn. The results in the cases suited for wet dressings are just as good with boric acid solution.

THE TREATMENT OF EMPYEMA, PLEURITIC EFFUSION AND HYDROCELE WITH SODIUM BIBORATE SOLUTION

J. P. ESCH, M.D.
DAYTONA BEACH, FLA.

So much has been said recently about the treatment of empyema and pleurisy with effusion that I venture to give a method which I first employed in 1883 and have since used, whenever opportunity offered, with complete success in pleuritic effusion, empyema and hydrocele.

History.—The first case in which I used the treatment was that of C. S., a boy about 10 years old, who became ill with pleurisy, followed by an effusion filling the right side of the chest. I deferred withdrawing the fluid as long as I could and empyema followed. I then aspirated, withdrawing about a pint and a half of creamy pus, but the chest soon filled up again, and again I aspirated, withdrawing nearly the same amount of pus. This was repeated seven times and the amount of pus withdrawn was about the same each time. I had been experimenting with a solution of biborate of soda in patients with hydrocele, and as that had checked the effusion in each instance I concluded to try it in this patient. After withdrawing the pus I injected about a pint of a 2 per cent. solution of biborate of soda at a temperature of 100, allowing the solution to remain in the cavity for about ten minutes, moving the patient gently so as to bring the solution in contact with every part of the cavity. I then withdrew all the solution, and that was the end of the empyema, for the patient made a rapid recovery.

My next patient had simple pleurisy with effusion. I aspirated but did not wash the cavity out with the biborate solution, as these patients often recover after aspiration; but the chest soon filled up again and I aspirated again, this time washing out the cavity with the biborate solution. This ended the trouble.

My next patient was a man of about 70 with hydrocele. The effusion had been aspirated three times, and the sac had refilled each time. I aspirated, and washed out the sac with the biborate solution, left it in about fifteen minutes, then withdrew it, strapped the scrotum, and sent the patient home. Although he lived for ten years after that he never had a recurrence.

Since that time I have used the biborate solution in nearly every case, and always with success. One great point in its favor is the fact that it is quite painless, and any one who has seen a patient writhe under an injection of iodin or carbolic acid will appreciate this.

Therapeutics

WHOOPING COUGH

Although whooping cough, or pertussis, has long been recognized as one of the most conspicuous examples of an infectious disease, and that it is also directly contagious, still, the agent of the infection has not been definitely determined. Some have believed that it was a protozoon, to which class belong the plasmodium, the infecting agent of the malarial diseases. Others have found a bacillus resembling the bacillus of influenza, which they believe is the cause of whooping cough. At present the opinion of the majority of those who have personally investigated the subject seems to be in favor of accepting this bacillus as the cause of the infection.

As the disease is exceedingly contagious, and its complications and sequelæ (pneumonia, phthisis, heart strain, cerebral hemorrhage, ocular hemorrhage) are often exceedingly dangerous, it is not at all necessary to present any argument in favor of the isolation of those who are suffering with it. This isolation should be put into effect as soon as the disease is recognized. But it commences so insidiously, its early symptoms are usually so closely identical with those of an ordinary "cold" commencing "in the head" or nose, and affecting later the bronchi, and causing a cough, and the characteristic whoop is so late in appearing, that two or three weeks often elapse before a positive diagnosis is made. Here the scientific precision of the laboratory comes most usefully to the aid of the physician, for it has been found that in whooping cough, even early in the disease, there is a pronounced leucocytosis. If, when the symptoms seem to point to the possible presence of whooping cough, a pronounced leucocytosis is found, it is strong confirmatory evidence that that disease is actually present. But if, on the other hand, there is no leucocytosis, it is probable that it is not the early stage of that disease.

The necessity of giving children with the disease abundance of fresh air is now generally recognized. This rule, however, has not always been carried into effect with as much common sense as is desirable. By many persons the direction by the physician to give the patient plenty of fresh air is interpreted as a command to expose him to out-of-door air without regard to its temperature or the direction and force of the wind. It is hardly necessary to present any argument to the practitioner of experience that the exposure of any individual to air of extremely low temperature or to cold winds and drafts is exceedingly likely to be followed by inflammatory affections of the respiratory organs. Much more are such unfortunate results likely to follow, and their incidence likely to be more severe, when the victim of the exposure is already suffering from whooping cough. If the patient comes under treatment in the summer he may be kept out of doors most of the time, if he is not severely affected by the disease. This does not mean that he should be allowed to play hard and become overheated or exhausted. In mild spring and autumn weather, quiet enjoyment of outdoor air is advisable, but in winter when the temperature is low, and especially if damp, and when there are cold winds, it should be emphasized that exposure during whooping cough is dangerous. But not all patients can be allowed to go out of doors. If there is fever, or if the paroxysms are severe or frequent, rest in bed is essential, or in warm weather rest on a veranda. If in the intervals between the paroxysms the child shows signs of being sick, his temperature should be accurately taken, and if it is 100 F. or over he should be kept in bed until it returns to normal.

Food should be of an easily digestible character and given at regular intervals. If vomiting is of frequent occurrence, the food should be given in small quantities, and at more frequent intervals, which should usually be three hours.

Concerning medicinal treatment, opinion and practice vary greatly. Most of the drugs which have been extensively used may be classed as antiseptics or antispasmodics, and either of these classes is favored in proportion as the individual practitioner is inclined to consider the infection or the spasmodic element as furnishing in the first case a more rational, or in the second case a more imperative indication for treatment.

Forty years ago Binz claimed that sulphate of quinin was a specific in whooping cough if given in solution so as to come in contact with the mucous membrane of the mouth and throat, believing that in this way it destroyed the micro-organisms which caused the disease.

The antispasmodics which have been used with the idea that the neurotic element of the disease was the most important, and could be most satisfactorily influenced by treatment, are too numerous to permit even of their enumeration.

Many years ago French clinicians advised the administration of belladonna, but it has never come into very general use. Its best effects are seen only when it is pushed until its physiologic effects are apparent, and these are so disagreeable, not to say terrifying, that most persons would rather endure, or have their children endure, the paroxysms of the disease than the dryness of the throat, the hyperemia of the skin, the impairment of vision, and the cerebral disturbances which are likely to follow the use of large doses of belladonna.

The bromids have been recommended, but rarely are the phenomena of whooping cough of so purely reflex character that these salts alone prove of much avail, although they may be useful in quieting the general restlessness and nervousness sometimes seen in these patients.

Antipyrin has been highly praised and extensively used, and assists greatly in palliating the paroxysms, but many hesitate to use, in a disease which lasts usually for several weeks, a drug which has been reputed to have very deleterious effects on the blood and the heart. If properly used, however, antipyrin is one of the most successful treatments in whooping cough. It should be given in 0.05 gram (5/6 of a grain) doses for every year and a half of age of the child, i. e., 0.05 gram for a child up to one and one-half years of age; 0.10 gram for one and one-half to three years of age; 0.15 gram from three to four and one-half years; 0.20 gram (3 grains) from four and one-half to six years of age, and so on, and this dose administered three or four times in twenty-four hours. The little patient should be given coincidently one drop of the tincture of digitalis three times a day for every one and one-half years of age. The antipyrin may be prescribed as follows:

℞.	gm. or c.c.		
Antipyrini	3		gr. xv
Syrupi	50	or	fl.℥iss
Aquæ menthæ piperitæ, ad	100		ad, fl.℥iii

M. et Sig.: A teaspoonful, in water, three or four times a day.

[This would be the dose of antipyrin for a child from three to four and one-half years of age.]

The digitalis should be ordered separately, so that its dose may be increased or diminished according to the rate of the pulse. The digitalis not only prevents the antipyrin from having any weakening action on the heart, but also helps the heart to withstand the strain on it from the cough.

Whatever the treatment may be, its success may be determined by the frequency of the paroxysms of coughing, and the mother or nurse should keep a careful record of these day by day, so that the record of yesterday may be compared with that of to-day, and the medicine increased, diminished or continued according to the results.

If there is much bronchitis, it may be necessary to give an ammonium chlorid expectorant mixture, with or without opium in some form. Also, if the child is very weak, it may be necessary to reduce the intensity and frequency of the paroxysms by some form of opium. With the rest and antipyrin treatment, however, it is rarely necessary. The best form in which to administer opium to a young child is small doses of codein sulphate or the tincture of deodorated opium. The latter should be ordered separately, and a drop administered to a child two years old or more, every two, three or four hours, depending on its action. If the child is drowsy, the mother or nurse should be told to stop its administration.

After the paroxysms have practically ceased, some form of tonic is needed, and perhaps nothing is better than an *eisenzucker* (saccharated oxid of iron), three-grain tablet, three times a day, or syrup of hypophosphites may be ordered, or cod-liver oil in small doses may be administered, or some emulsion of fats or cod-liver oil. Be the tonic treatment what it may, it should be persisted in, with plenty of outdoor air and perhaps change of climate, until the child has ceased to cough, has regained its weight, and has recovered or attained a normal healthy color; in other words, until its general condition and blood condition are all that could be desired. Until the child has reached this condition of health there is danger of tuberculosis becoming a sequel of the whooping cough.

Some practitioners think that the cough is less intense, the vomiting less frequent, and the general condition of the patient improved by either an elastic band worn about the abdomen, or adhesive straps, or a firmly applied abdominal bandage. Such mechanical measures can certainly do no harm, and may often do good.

The administration of chloroform to do necessary operations on children who have had whooping cough has in many instances seemed to abort the disease. It has, therefore, been suggested that chloroform be administered once or twice early in the disease to see if it would kill or prevent the growth of the whooping cough germ. Not sufficient statistics have yet been offered to show its value, however, and its use for this purpose is, therefore, purely experimental.

The old treatment of taking children with whooping cough to the gasometers for the purpose of subjecting them to the inhalation of coal gas fumes is now probably rarely tried. If the inhalation of this kind of coal gas was valuable in killing the disease, the toxic gases occurring in the new methods of making illuminating gas would seem to render the subjection of a child to these gases very inadvisable.

The various antiseptic sprays recommended do not seem to reach the seat of the disease or to do very much good, and probably boric acid sprays and boric acid gargles are as antiseptic and as safe and cleansing as any local treatment that could be safely advised.

The treatment of whooping cough may be summed up as:

1. Rest.
2. Fresh air.
3. Food every three hours in not too large quantities. (If a meal is lost by a paroxysm and vomiting, the child should be given another meal immediately, as it is likely another paroxysm will not quickly occur.)
4. Warm baths.
5. Boric acid mouth wash and gargle.
6. The bowels should be moved daily with cascara, if needed.
7. Iron in some pleasant form.
8. Antipyrin, if the paroxysms are at all severe, in the dose above described, and with the coincident administration of tincture digitalis.
9. If antipyrin is inadvisable or not successful, codein or tincture of deodorated opium should be given.
10. Later tonics, food, and hygiene best suited to each individual patient.

THE AMERICAN MEDICAL ASSOCIATION—ITS POLICIES AND ITS WORK

IV. THE REORGANIZATION OF THE STATE AND COUNTY SOCIETIES

BEFORE REORGANIZATION

Two weeks ago we called attention to the necessities and results of organization, so far as the American Medical Association was concerned. Much that was said then will also apply to the state societies. Previous to 1901 they were practically isolated organizations, with little actual connection between them and the local societies. In some instances their relation to the American Medical Association was not even nominal, and in no case was it close and vital. They were entitled to send delegates to the American Medical Association, but the smallest local body had the same right. There was no uniformity as to plan of organization or requirements for membership.

The state society was in no sense representative, and it usually comprised but a minor fraction of the physicians of the state. The annual meetings were merely voluntary gatherings of men for scientific and social purposes; and anything outside of scientific work was seldom attempted. Little time was given to the discussion of business or to constructive work, unless the passing of resolutions might be so regarded. Little, if any, effort was made to build up local societies, and so far as accomplishing anything during the interval between the annual meetings was concerned, for all practical purposes there might as well have been no state society. In other words, the state societies before reorganization, with four or five exceptions,[1] were simply independent bodies, with no close or uniform relationship to each other,[2] meeting annually for scientific purposes, and in no way so constituted as to represent the profession of the whole state, or to do constructive work.

The conditions regarding local societies were as bad, if not worse. Previous to reorganization, there were few, if any, strictly "county" societies, except in a few states.[1] Local organizations were to be found only in the larger towns. District societies had no definite territory and were voluntary organizations, usually meeting but once a year. The membership of the local bodies generally comprised an extremely small fraction of the physicians in the locality, and often was limited to friends of certain individuals, to the staffs of certain hospitals, or to members of the faculty of a certain college; often rival societies were organized by rival cliques and circles in the same town; in a few instances these were actually detrimental—breeders of jealousy and strife, and tending more to disorganization than to organization.[3] They were, in short, isolated units with nothing in common, and had slight connection with the state society.

Most important of all was the fact that the existing local societies did not afford opportunity for membership to physicians in small towns or rural districts. Consequently, such men were practically barred from attendance at medical societies, except at great sacrifice of time and money, such as the majority were neither able nor willing to make. The results of these conditions were that thousands of physicians were beyond the reach of medical societies, while many thousands more did not hold membership because the existing societies did not appeal to them.

Such, in brief, were the general conditions prevailing, previous to 1901. These unsatisfactory conditions had long been realized by progressive members of the profession and, as shown by the annual transactions of many state societies, had been frequently discussed and numerous suggestions made for their betterment. Thus when—in 1901—the American Medical Association proposed a definite and uniform plan of organization, the time was ripe for action, and the opportunity was immediately grasped. Several of the state societies did not even wait for the adoption of the report by the American Medical Association, but actually modified their organic laws to conform to the proposed plan, while it was still a tentative one. Following the adoption of the report, a large number of state societies undertook the work of reorganization. So eagerly was the plan taken up, that in 1902 requests were made that a model constitution for state organizations be prepared so that all could conform to a uniform plan. The next year a similar request was made for a model constitution for county societies, and this also was ordered prepared.

---

[1] The statements made in this editorial must be regarded as a general summary of the conditions of the country as a whole. Exceptions must be made as to certain states. For instance, Massachusetts had for a long time been organized on a very effective and practical "district" plan. Alabama, in the early seventies, adopted an excellent scheme of organization which, in fact, was the ideal before the committee in working up the proposed plan. The Medical Society of the State of New York and the New York State Medical Association each had a county society system, but the existence of these two rival bodies largely counteracted the good results which might have been secured. Besides these, Connecticut, Indiana, New Jersey and Pennsylvania were organized on some variation of the county plan.

[2] Said the Committee on Reorganization in their report in 1901: "It is not necessary to use arguments to prove that there is at present no close relationship among the state societies; that each is acting as an independent body, recognizing no other; that no concert of action among them regarding measures that are of mutual importance is possible under present circumstances, and that a federation of the state societies is desirable and absolutely necessary for the accomplishment of their full measure of usefulness."

[3] "One of the great obstacles to systematic organization is the large number of existing medical societies. Of these there are between 1,300 and 1,400, although with new ones continually starting and with many in that condition of innocuous desuetude which makes it hard to decide whether they are alive or dead, it is impossible to even pretend to any correctness as to the number. For the reason that most of these are organized without any common plan and without relationship one to the other, they are a source of weakness and an obstacle to systematic organization." From the Report of the Committee on Reorganization, 1901.

REORGANIZATION

And what, after all, were the changes which have produced such marvelous results in so short a time? Like those made in the American Medical Association, they were apparently very slight and yet so fundamental as practically to revolutionize existing conditions and to make possible a systematic, practical organization of the profession.

The first and basic principle of reorganization was the recognition of the importance of the local or county society. It was realized that only through it could the individual physician be reached. "Such societies would furnish to every physician the opportunity of membership with the professional, social and material stimulus and betterment incident thereto." So the local society was made the unit or foundation of the whole superstructure. This unit also was made to cover a definite area—a county. The county society was made the "portal of entry" to all above it. To be a member of, or to retain membership in, the state or national associations, one must be a member of this unit—his county society. Before the reorganization, a physician might be a member of either the state or the national body, and yet not be a member of any subordinate society.

The second principle relates to representation. A state legislative or business body was created—the House of Delegates—in which are federated the county societies and to which each county society is entitled to send delegates, in proportion to its membership. These delegates are the representatives of their society; before reorganization, those who attended the state society represented themselves only. As was shown in the preceding editorial, the reorganization restricted to the state societies the right to send delegates to the American Medical Association; here that right of representation in the national body is restored.

Thus the reorganization means that the individual physicians of a county form the county society; that the county societies, through a delegate system, are federated in and form the House of Delegates of the state association; that the state associations, through a delegate system, are federated in and form the House of Delegates of the American Medical Association.

The third principle is that membership in the county society carries with it membership in the state society. This means the right to attend the annual meetings and to take part in the scientific work and in the social functions; it does not mean the right to vote or to take part in the legislative or business affairs. This right belongs to those selected for that purpose by the county societies—the delegates.

The above, in brief, are the general principles of the plan of organization of the profession adopted in 1901—the plan which now exists in every state and territory except one. Let it be emphasized that this plan was not originated in 1901; it had been suggested and discussed long before that time.[4]

RESULTS

What are the results? The first and most noticeable has been the increase in membership. The prediction that the change would result in enormous increase in membership in county, state and national bodies has been realized. It is impossible to show by actual figures the increase in membership, since, in 1901, there was no way of ascertaining even the names of existing societies, much less the membership. The same applies, to a certain extent, to the increase in membership in state societies. Some idea can be obtained, however, from the report of the general secretary made to the House of Delegates in 1901, in which the increase for ten years is shown. In 1899, for instance, the Illinois State Medical Society had a total nominal membership of a little over 500, but, according to the *Transactions,* only approximately 300 members paid dues for that year. At present, this society has an actual membership of about 5,300. The State Medical Association of Texas in 1899 had a membership of 297; to-day it has over 3,100. Previous to reorganization, there were estimated to be between 1,100 and 1,200 local societies, largely confined to the more populous areas, uncorrelated, disorganized, overlapping in territory, and often conflicting in purpose and object. Now there are 2,287 county societies, uniform in organization, each having jurisdiction over its own allotted territory, united for mutual improvement and helpfulness and gaining each year in strength and influence. The total membership of these societies is a little over 70,000. To-day a medical society is within the reach of practically every physician in the country.

---

[4] The following from the report of the Committee on Organization, of which Dr. N. S. Davis was chairman, is interesting in this connection: "By making membership in a local [county] society a necessary qualification for membership in the state and national societies, the strongest possible inducement is presented for organizing and maintaining these primary and essential bodies by all intelligent members of the profession. By providing for delegates from the local and state societies on a uniform ratio of representation, and placing the whole business management of the Association in the hands of such delegates by restricting to them the right of voting, the most reliable check is put upon the tendency to centralization or local control, or any form of class supremacy, while the door to permanent membership is opened to all who are willing to support the interests of the profession in their own districts." (See THE JOURNAL A. M. A., June 25, 1887.)

The establishment of the councilor system, providing for a board of trustees or directors, and the appointment of numerous standing and special committees, have made the state society an organization in continuous existence, ready at any time to take up matters of interest to the profession and to the public, instead of being simply an annual mass-meeting, practically non-existent during the interval. The work now being done by committees of state associations, such as those on medical legislation, public health, medical and public education, and on other important matters, would have been utterly impossible under the old conditions. The affiliation of all county societies with the state society has made possible the appointment of committees containing representatives from each county society, thus giving the county societies a part in the work of state associations, and an opportunity to cooperate with each other.

Some one has observed that every proposition is ultimately one of finance. Medical organization is no exception. The enlarged membership has made for financial strength. Under the old order the state society dues varied from $2.00 to $5.00, but a comparatively few contributed, the dues being paid chiefly by those who were able to attend the annual meetings. Now each contributes a smaller amount, but from the many this makes a larger total income—and the enlarged possibilities for work and usefulness due to increased income are obvious.

Under the old plan, state societies published "transactions," which usually appeared many months after the meeting, and the publication of which in many states practically absorbed the annual income. Ten years ago not a single state society owned and published a journal; to-day there are twenty-two state society journals, representing twenty-four state societies.

Twelve states have adopted the mutual defense plan in malpractice cases, and are able, at a purely nominal cost, to protect their members against malpractice suits. Many other states are considering the question, and it is probable that ultimately most of the state associations will have added this feature to their membership privileges.

The best result of all, however, is the newer, better feeling now prevailing among physicians themselves, brought about by meeting and knowing each other. There is now a more fraternal feeling than formerly, and as a result less of the old-time jealousy and bickering—long the curse of the profession. There has developed a spirit of true fraternal professional cooperation and mutual helpfulness, which has in many places practically revolutionized conditions in the profession, and wonderfully increased its influence. It was formerly impossible to unite physicians of a state on questions of public policy or to present a united front. To-day it is entirely different. Like the bundle of sticks in the old fable, the profession is now bound together in a compact and coherent body which cannot be affected from without and can be broken only by disunion from within.

The value of a harmonious and united profession earnestly striving for the uplifting of its own standards, is evident; untold good has already resulted, both to the public and to physicians themselves; and yet we are only just beginning to realize the power and possibilities for usefulness of a united profession.

In a future issue we shall discuss in more detail certain other phases of organization.

THE ANTIVIVISECTION AGITATION IN NEW YORK

Again this year an antivivisection bill has been introduced into the New York legislature, and, after a hearing, the committee of the assembly has again refused a favorable report. Eager to obtain some sort of advantage, however, the agitators for legislation have just succeeded in presenting a second bill, providing for a commission to investigate "into the practice of vivisection or experimentation on living animals and the amount of suffering involved therein." The bill authorizes the commission to send for persons or papers, to administer oaths, and to examine witnesses and papers regarding the subject. The proposed commission would consist of seven persons, two physicians or scientific men, two active members of "an organization for the prevention of cruelty in vivisection," two practicing lawyers, and a seventh member appointed at large. A sum of $5,000 is provided for expenses.

The agitation in New York is mainly due to the activity of one newspaper. The New York *Herald*, stung by the success of the county medical society in forcing from its columns advertising matter subversive of public health and morality, retaliated by taking sides with the opponents of medical research. In an apparently malicious spirit the paper has published day after day most misleading accounts of laboratory procedures, topped by large headlines referring to the "tortures," the "torments," the "prolonged agonies," suffered by experimental animals. The falsity of these statements and inferences has been repeatedly made clear in public letters, but the appeal to prejudice and suspicion has not been checked. As a result a state of extreme feeling has been aroused in some worthy persons, a condition remarkably like that in Great Britain in 1875, when the first Royal Commission on Vivisection was appointed.

That commission thoroughly investigated the conditions in the laboratories, found no material abuses, and on reporting made certain recommendations. As a writer in *Nature* put it at the time, "The evidence on the strength of which legislation was recommended went beyond the facts, the report went beyond the evidence, the recommendations beyond the report, and the bill can hardly be said to have gone beyond the recommendations, but rather to have contradicted them." It was a drastic bill passed in the heat of the agitation. For thirty-four years this law has been enforced, seriously interfering with medical research in Great Britain. What has been the effect? Antivivisection societies have multiplied—fifteen societies in Great Britain are energetically striving for the absolute abolition of animal experimentation. In 1906 these societies obtained the appointment of another commission; the voluminous testimony before it proved overwhelmingly how baseless were the insinuations of the agitators!

The Council on Defense of Medical Research has made a careful investigation of all American medical schools and laboratories in which animal experimentation is carried on, and has obtained detailed reports. The investigation has shown that every care is taken to avoid the infliction of pain. Practically all of the laboratories engaged in active research have voluntarily adopted regulations which state the conditions and express the spirit in which animals are used for experimentation. The responsibility to public interest in the importance of the problems studied and in the propriety of the methods used in studying them is placed by these regulations definitely on the person most concerned and most trustworthy, the person most likely to know at all times what is being done—the director of the laboratory. Any procedure involving greater distress than that accompanying anesthetization can be used only with the director's sanction. In several instances such regulations have been enforced for many years.

As the British experience indicates, the discovery of satisfactory conditions in the medical laboratories will have no effect in allaying the antivivisection agitation, for, quite apart from the fanatical element in the movement, there is money, which, bequeathed to antivivisection societies, must be used. In response to the present excitement, New York may, indeed, spend $5,000 of public funds for an investigation. That investigation, however, has already been made by a Council of this Association, and reliable safeguards against the careless use of animals are already in existence. The immediate situation, therefore, is one which, if the bill passes, the medical profession may face with equanimity.

Cause for anxiety, however, may later arise, if, as in Great Britain, clamor forces legislation hostile to the laboratories. For the sake of public health the medical profession should urge that medical research be controlled within professional lines, and not by hampering and entangling conditions expressed in short-sighted legislation.

THE EFFECTS OF ALCOHOL AND CHANGES IN TEMPERATURE ON ANTIBODY FORMATION

When it was shown experimentally that the natural resistance of animals to infection with various bacteria may be influenced by hunger, thirst, overexertion, abnormal heat and cold, poisons and a number of other factors, the question quickly arose as to just how modifications of resistance are produced. At first this question was approached from different and for a time mutually exclusive points of view, namely, that provided by the phagocytic and that provided by the humoral theories of antibacterial immunity. At first the advantage seemed to be with the phagocytic theory because it dealt with dynamic reactions, whereas the humoral theory was concerned with substances that then were looked on as altogether preformed and more or less stationary. However, when it became apparent that the antibodies of the humoral theory were subject not only to fluctuation, but also to new formation under the stimulus of infecting agents and in consequence of cellular reactions, the question whether means that modify resistance have any influence on the course of formation of antibodies soon suggested itself. A number of investigations have been carried out with this thought in mind to determine the effect of various factors on antibody formation.

According to Trommsdorff,[1] severe physical exhaustion, prolonged hunger, and great chilling of the body, as well as certain other factors that are known to lower resistance, all lessen the production of antibodies in immunized animals. With respect to the effects of alcohol in rabbits, the results of Müller,[2] Wirgin[3] and others indicate that alcohol in mildly intoxicating quantities for several days after the injection of the antigen restrains the formation of antibodies. Wirgin found about 5,300. The State Medical Association of Texas in 1899 had a membership of 297; to-day it has over 3,100. Previous to reorganization, there were estimated to be between 1,100 and 1,200 local societies, largely confined to the more populous areas, uncorrelated, disorganized, overlapping in territory, and often conflicting in purpose and object. Now there are 2,287 county societies, uniform in organization, each having jurisdiction over its own allotted territory, united for mutual improvement and helpfulness and gaining each year in strength and influence. The total membership of these societies is a little over 70,000. To-day a medical society is within the reach of practically every physician in the country.

There has developed a spirit of true fraternal professional cooperation and mutual helpfulness, which has in many places practically revolutionized conditions in the profession, and wonderfully increased its influence. It was formerly impossible to unite physicians of a state on questions of public policy or to present a united front. To-day it is entirely different. Like the bundle of sticks in the old fable, the profession is now bound together in a compact and coherent body which cannot be affected from without and can be broken only by disunion from within.

The value of a harmonious and united profession earnestly striving for the uplifting of its own standards, is evident; untold good has already resulted, both to the public and to physicians themselves; and yet we are only just beginning to realize the power and possibilities for usefulness of a united profession.

In a future issue we shall discuss in more detail certain other phases of organization.

THE ANTIVIVISECTION AGITATION IN NEW YORK

Again this year an antivivisection bill has been introduced into the New York legislature, and, after a hearing, the committee of the assembly has again refused a favorable report. Eager to obtain some sort of advantage, however, the agitators for legislation have just succeeded in presenting a second bill, providing for a commission to investigate "into the practice of vivisection or experimentation on living animals and the amount of suffering involved therein." The bill authorizes the commission to send for persons or papers, to administer oaths, and to examine witnesses and papers regarding the subject. The proposed commission would consist of seven persons, two physicians or scientific men, two active members of "an organization for the prevention of cruelty in vivisection," two practicing lawyers, and a seventh member appointed at large. A sum of $5,000 is provided for expenses.

for nearly a year, reports great improvement.——Dr. William A. Crooks, for eleven years assistant superintendent at Watertown State Hospital, was appointed superintendent by the State Board of Administration, March 21, vice Dr. Warren E. Taylor, resigned.

Chicago

Relief of Consumptives.—The Young Woman's Auxiliary of the Jewish Consumptive Relief Society netted $3,000 for the work in an entertainment given at Mount Sinai Temple, March 13.

Red Cross Endowment Committee.—The president has made the following Chicago appointments to the membership of the endowment committee of the American Red Cross: Cyrus Hall McCormick, John V. Farwell, Edward B. Butler, W. G. Shedd, Charles G. Dawes and John J. Mitchell.

Children's Isolation Hospital.—Dr. Anna Dwyer proposes to erect a hospital for the treatment of contagious diseases of children, to be paid for by the money donated by school children of the city, and suggests the erection of the building on land adjoining the Mary Thompson Hospital.

Unlicensed Practitioners Fined.—Municipal Judge Scovill imposed fines of $100 and costs on each of six individuals who had been found guilty of practicing medicine without a license, had pleaded guilty and agreed to accept the maximum fine. The prosecutions were undertaken by the State Board of Health.

Hospital Day Association.—The Chicago Hospital Day Association, chartered in February to promote organized and systematic charity giving for the support of hospitals in Cook county working under church patronage, will hold its first collections on May 1 and 2. The hospitals of the Methodist, Roman Catholic, Baptist and Presbyterian denominations have taken out active membership.

Personal.—Dr. Strother J. Beeson has returned from a trip around the world.——Dr. and Mrs. Mathias J. Seifert left March 15 for the Gulf Coast and Mexico.——Dr. and Mrs. E. Fletcher Ingals have returned from the South.——Mr. Elbert Clark, associate in anatomy in the University of Chicago and Rush Medical College, who has been appointed assistant professor of anatomy in the University of Manila, the Philippine Medical School, left Chicago March 19 to take up the duties of his new position.——Dr. Daniel W. Rogers has been appointed chief sanitary officer and medical inspector The Division, Illinois National Guard, with the rank of major.

IOWA

Antitoxin to be Sold at Cost.—The State Board of Health announces that it will supply antitoxin for diphtheria for the people of the state at cost.

New Building for Hospital.—A contract for the erection of the new Drake University Medical School Hospital, Des Moines, has been awarded. A three-story residence is to be remodeled and a three-story addition built.

Supreme Court Sustains State Board.—The Supreme Court, on February 10, decided that practitioners of "vital science" must be licensed by the State Board of Medical Examiners, and sustained the conviction of L. M. Adkins, Grinnell, convicted of practicing medicine without a license.

Practically Acquitted.—The Supreme Court has handed down a decision in the case of Dr. Franklin W. Sells, Osceola, who was found guilty of an attempt at criminal assault. The opinion granting him a new trial, suggests that unless the state is able to offer additional and further proof in support of the indictment, it will be advisable for the prosecution to enter dismissal.

Crofford Pardoned.—Dr. J. W. Crofford, Lamoni, sentenced to twelve years' imprisonment in the penitentiary on the ground that he had performed a criminal operation which resulted in the death of a young girl, was pardoned by the governor on the recommendation of the pardon board, February 26. The pardon is based on the affidavit of Dr. Artemas Brown of Des Moines, formerly of Leon, who testified that the girl came to him stating that she had had a criminal operation performed on her before she consulted Dr. Crofford.

Society Meetings.—The sixth annual meeting of the Southwestern Iowa Medical Association was held in Albia, February 17. Dr. Samuel L. Hauck, Ottumwa, was elected president; Dr. Frank E. Sampson, Creston, vice-president; Dr. Enos Mitchell, Osceola, secretary-treasurer. The next meeting of the society will be held in Creston.——At the annual meeting of the Waterloo Medical Association, March 2, Dr. DeWitt C. Huntoon was elected president; Dr. John O. A. Scroggy, vice-president, and Dr. Wayne M. Shirley, secretary.

Campaign Against Quacks.—The legislative committee of Page county and the county attorney have been untiring in their efforts to rid that part of the state of fraudulent and unlicensed healers. H. B. Yates, a so-called "magnetic healer," is said to have been recently convicted and fined a second time for illegal practice. The case was taken to the Supreme Court and remanded for new trial, and the defendant was again convicted. Another indictment is still pending, covering the period of practice since the first indictment.——A cancer cure specialist, with headquarters at St. Joseph, Mo., is said to have been convicted of illegal practice and a $300 fine imposed.

Personal.—Dr. Joseph J. Flannery, Des Moines, who has been seriously ill, was discharged from Mercy Hospital, March 4, recovered.——Dr. William R. Wall, Folsom, celebrated his eighty-eighth birthday anniversary, February 28.——Dr. Lee Weber, Davenport, lost the middle finger of his right hand on account of septicemia, due to a needle wound.——Dr. Fred P. Bellinger, Council Bluffs, has returned from Europe.——Dr. Harry Francis Rubel, Waverly, is in a hospital in Waterloo, on account of septicemia due to an operation wound.——Dr. Mathew A. Tinley has recovered from his recent attack of appendicitis and resumed practice.——Dr. Mary M. Nelson, Marshalltown, sustained severe injury in a runaway accident recently.——Dr. Mark E. Brown, Clinton, who has been seriously ill with heart disease, is slightly improved.——Dr. Samuel W. Moorehead has been reappointed postmaster of Keokuk.——Dr. Forest G. Weber, Cherokee, has been seriously ill with typhoid fever.——The office of Dr. Ervin W. Warner, Delhi, was destroyed by fire, February 9.——Several hundred dollars damage was done by fire to the residence of Dr. Ira D. Kauffman, State Center, February 9.——Dr. George W. Greaves, Spencer, who has been critically ill with cerebral hemorrhage, is reported to be improving.——Dr. Elijah W. Jay, Marshalltown, coroner of Marshall county, while going to a train in an ambulance to meet the wounded from the train wreck which occurred near Green Mountain, March 21, was thrown to the pavement and sustained severe injuries to the spine.

KENTUCKY

Personal.—Dr. Bernard McEuen, St. Charles, has been appointed house physician for the State Insane Hospital, Chattahoochee, Fla.

Bring Pressure to Bear on Governor.—The council of the Kentucky State Medical Association met in Frankfort, March 12, to urge the governor to approve the appropriation bill granting $30,000 to the Kentucky State Board of Health, the vital statistics bill, and the anti-abortion bill. The governor is said to have made no promises, but is reported to have signed the appropriation bill for the State Board of Health, March 16.

New Medical Association Formed.—The Louisville Society of Medicine was organized March 15 without capital stock, for the purpose of medical research and to promote good will and fellowship. The membership is limited to thirty and each year one honorary member is to be chosen. The following physicians are the incorporators: Drs. Waller O. Green, Richard T. Yoe, Thomas K. Van Zandt, John D. Trawick, Alphons R. Bizot, Claude G. Hoffman, Curran Pope, William J. Young, R. Alexander Bate, Edward C. Redmon, Vernon Robins, Thomas A. Hays, Herbert M. McConathy and John D. Hamilton.

Follow-Up System in School Inspection.—A follow-up system has been inaugurated between school inspectors of the Louisville Health Department and the Associated Charities. The school inspection has resulted in great good, but much work has gone for naught either through neglect or ignorance. Slips are given children found abnormal, defective or diseased, describing the defect, and these slips are meant to be taken to the parents by the children, but in many instances no attention is paid to them. By the cooperation inaugurated, workers from the Associated Charities, follow-up those cases in which operation or special treatment has been advised and see that this is carried out. If it should prove to be the case that the family has no regular physician the child is looked after at clinics and if anemia and evidence of malnutrition are present, the home life and surroundings are investigated and any defects remedied.

The Babies' Milk Fund.—The Jefferson County Fiscal Court, on March 15, appropriated $500 to the Louisville Babies' Milk Fund Association for its work during the coming summer. The general council appropriated $1,500 in February for this purpose and the balance of the $5,000 said to be needed for the work is to be raised by voluntary contributions of citizens.

It is proposed to reopen on May 1 the six milk distributing stations which were opened last year, with a trained nurse and station physician in each, and later to open additional stations in other thickly populated parts of the city. One station is to be located in a room of the new shelter house erected on one of the interior squares, especially provided for the commission by the park board. This is said to be the first time that a private philanthropy has been officially recognized in this way. The death rate in Louisville among the infant population for the last five years was 23 per cent., while that of the milk station babies, many of whom were very ill when application was made for milk, was only 6 per cent. The work of the association is a most important factor in lowering the death rate of children under 5 years of age.

MARYLAND

County Commissioners as Board of Health.—A bill has been introduced in the legislature, making the board of county commissioners of Howard county, the board of health of the county.

Physical Education for Women.—The Woman's Physical Education Association has been organized at Baltimore with Dr. Lillian Welsh as president, with the object of awakening a wider and more intelligent interest in physical education for women, and of laboring for the improvement and extension of gymnastic games and athletics among women and girls.

Maryland Alumni Meet.—At the annual reunion of the Maryland Alumni of the University of Pennsylvania, held in Baltimore, March 17, the following officers were elected: President, Dr. Joseph C. Bloodgood, Baltimore; vice-presidents, Drs. Howard A. Kelly, Baltimore, Clotworthy Birnie, Taneytown, J. McPherson Scott, Hagerstown, and Charles M. Ellis, Elkton; secretary, Dr. Daniel Z. Dunott, Baltimore, and treasurer, Dr. Wilbur M. Pearce, Baltimore.

Pleas for Hospital.—Dr. George W. Todd, Salisbury, and others, came before the Senate Finance Committee, March 10, and asked state aid to the extent of $3,000 for the Pine Bluff Sanatorium for Tuberculosis, near Salisbury.——Mercy Hospital, Baltimore, through two of the sisters of the institution, explained to the Committee on Ways and Means of the legislature, the work, the plans and hopes of the institution. They ask $15,000 a year for maintenance of the hospital, and $50,000 for new buildings.

County Society Endorses State Care of Insane.—The Baltimore County Medical Association, on the recommendation of Dr. Edward N. Brush of the Shepherd and Enoch Pratt Hospital, has formally endorsed the bills at present before the legislature for the state care of the insane, especially insisting on the right of the Commission in Lunacy of unimpeded inspection of all institutions for the insane or mentally defective at any time, and the power of inquiring into the method of commitment, the authority for detention of such persons, and inquiry, furthermore, into any and all allegations of improper commitment or detention or unjust or harsh treatment, and putting into operation the legal means for correction thereof. The resolution of endorsement further asserts that powers of inquiry into dietary, methods of restraint, kind of treatment, and all other questions relating to the care, detention and treatment of the insane or mentally defective, are universally recognized as proper functions of state commissions in lunacy, and that possession of such powers, clearly defined and specified by law, has in the past, in other communities, resulted in material improvement in the care of the insane, and in an increased and increasing confidence on the part of the public in the institutions for the care of the insane in these communities.

MINNESOTA

Typhoid Inoculation.—Lieut. Col. William D. Bannister, chief surgeon at Fort Snelling, Minn., is to inoculate with typhoid serum sixty-five soldiers at Fort Snelling, who have volunteered for the purpose.

Illegal Practitioner Sentenced.—William Schieman, who holds what purports to be a diploma from the New York Institute of Science, giving him the right to practice medicine, charged with practicing medicine without a license in St. Paul, is said to have been found guilty, March 10, and sentenced to imprisonment for fifteen days in the workhouse.

New Hospital for Minneapolis.—Hill Crest Surgical Hospital was opened recently in Minneapolis. It is a private hospital, with accommodation for 35 patients, and is intended to give special service in surgery, gynecology and diseases of the eye, ear, nose and throat. The constitution forbids payment of dividends, all earnings being employed for betterment of the service. The staff is composed of Drs. J. Warren Little and Archa E. Wilcox, surgery; Dr. Charles G. Weston, gynecology, and Dr. Frank C. Todd, eye, ear, nose and throat.

The New University Hospital.—Ground will be broken for the first permanent building of the University Hospital as soon as the weather permits. The building will be completed about January 1 next, and will have accommodation for about 130 patients. The University Hospital service is being conducted for the time being in temporary hospital buildings having 42 beds and accommodations for the hospital nurses and helpers. The board of regents has authorized the employment of a medical superintendent for the hospital for the fiscal year, beginning August 1. The Committee on Hospital is open to receive applications from available candidates. Communications may be addressed to the secretary of the Committee on Hospital, University of Minnesota, Minneapolis.

MISSOURI

Medical Societies Merge.—At the March 8 meeting of the St. Joseph-Buchanan County Medical Society, held in St. Joseph, the Andrew County Medical Society was merged with the local and county organization.

Arrangements for State Association Meeting.—Marion County Medical Association has appointed a committee composed of Drs. Robert H. Goodier, Edward T. Hornback, Clifton R. Dudley, Isaac E. Hill and William H. Hays, all of Hannibal, to comple[illegible] for the convention of the Missouri State [illegible] at Hannibal, May 3-5.

Personal.—Dr. R. R. Price, Slater, has been elected assistant physician of State Hospital No. 3, Nevada, vice Dr. Enoch C. Haile, Carterville, resigned.——Dr. C. D. Hefflin, at one time a practitioner of Bolckow, and sentenced to the penitentiary in 1904 under a sentence of fifty years' imprisonment for assault, has been pardoned by the governor.——Dr. A. C. Pettijohn, Brookfield, was elected superintendent of the State Hospital for the Insane, No. 2, St. Joseph, March 14.——Dr. Charles A. Hinson, Revere, fell while attempting to board a freight train at Madison, March 15, and was seriously injured.——Dr. George N. Newman, Mount Vernon, was injured in a Rock Island train wreck near Green Mountain, Iowa, March 21.

St. Louis

Personal.—Dr. John B. Logan is reported to be seriously ill with cerebral hemorrhage.——Dr. Richard L. Barrington has been appointed a member of the local pension board.

Donation to Hospital.—A donation of $20,000 has been made to St. Louis University Medical School by Ambassador Richard C. Kerens, to be used as an endowment fund for beds for charity patients in the Rebekah Hospital.

New Hospital Bills.—The hospital bills at present before the legislature to reorganize the hospital system of St. Louis, provide for a hospital commission to be appointed by the mayor, a hospital commissioner similar to the present health commissioner, to be appointed by the hospital board, a resident staff and a supplementary visiting staff.

Site for Sanatorium Bought.—Will H. Young has transferred to the St. Louis Society for the Relief and Prevention of Tuberculosis ten acres of land about five miles from Kirkwood, near the Meramec River, on which the society expects to establish a sanatorium and day-camp for the use of patients. There is a six-room house on the property, which will be remodeled, and several tents have been donated to the society.

NEW YORK

Change at Cornell.—The trustees of Cornell University have decided to limit the work in the medical department at Ithaca to one year in the future instead of two as has been the custom hitherto. The remainder of the course may be taken in New York City. Since a four years' course was provided in New York City the registration at Ithaca has been lighter.

Tuberculosis Conference.—About 500 delegates attended the opening session of the tuberculosis conference at Albany, March 18. Dr. George W. Goler, health officer of Rochester, declared that tuberculosis was a school problem. More than 70 per cent. of school children were physically incompetent. He advocated open air school rooms and suggested leaving the top sash out of all windows. Dr. Oscar H. Rogers of Yonkers urged that children of the public schools be taught the dangers of tuberculosis since 50 per cent. of the adult population among the working classes died of it. He believed that especially the children of the lower grades should be taught its dangers.

Bills Before the Legislature.—A bill providing that the real estate owned by any hospital located in the City of New York, as now constituted, actually dedicated and used by such hospital exclusively for hospital purposes shall be exempt from the assessments for public improvements which are now levied against such real estate or which may hereafter be levied and assessed therefor in said city.——A bill to amend the education law by adding a section relative to the establishment of a State School of Sanitary Science and Public Health at Cornell University.——A bill amending the liquor tax law by providing that liquors shall not be sold to any patient affected with tuberculosis in a camp, colony or hospital established by the state, county or municipal authority, and under the management and control thereof, except on the written prescription from a physician to such colony, camp or hospital.——A bill amending the agricultural law relative to the definition of adulterated milk providing that milk containing less than 11½ per cent. of milk solids shall be accounted adulterated.——A bill amending the penal law by adding a new section relative to sepultures and the burial of the dead on the canal lands of the state.——A bill prohibiting the discharge of the effluent of sewage disposal plants, of the effluent from any plant for the treatment and disposal of any wastes from industrial or manufacturing establishments and refuse from any sewer or drainage system in addition to the garbage offal and other decaying matter referred to in the present law. It provides a procedure before the Commissioner of Health on the question of pollution by municipalities and provides that orders of the commissioner shall be approved of by the governor and the attorney-general and be enforced by the attorney-general.——A bill creating a Department of Public Hospitals for the City of New York. There is to be a board of trustees of nine members, three of whom shall be women. Provision is also made for a medical board, composed of attending and consulting physicians and surgeons of hospitals. The head of the department is to be known as the Commissioner of Hospitals. There is also a provision for a public ambulance system and training school for nurses.

New York City

To Enlarge Bellevue Insane Pavilion.—Plans have been filed for the enlargement of Bellevue Hospital by the addition of a two-story annex which will be connected with the present insane pavilion by a covered corridor and staircase. This annex will cost $16,000.

Transportation of the Insane.—Temporary care of the insane and their transportation from their places of residence to hospitals will be henceforth in the hands of the officials of Bellevue and the Allied Hospitals. The Bellevue trustees have asked authority to issue special revenue bonds to an amount not exceeding $8,000 for the purpose of meeting this additional expense.

Society Secures Convictions.—Kings County Medical Society is said to have secured two convictions in the court of special session, March 7. Maurice T. Schachter is said to have pleaded guilty of selling improper medicine to a woman, and to have been sentenced to the New York Penitentiary for three months; S. T. Silverman, who pleaded guilty to prescribing without proper license, was found guilty, but sentence was suspended.

Medical Chair Endowed.—Mrs. Helen Hartley Jenkins has offered to New York University a gift of $100,000 for the endowment of a chair of medicine in the University and Bellevue Hospital Medical College. The gift was made through Dr. A. Alexander Smith. The foundation will be named the Marcellus Hartley chair of medicine after Mrs. Jenkins' father, who was a member of the university corporation, and was also a member of the committee on the medical college from the time of the consolidation of the medical schools.

Personal.—Dr. M. Allen Starr has sailed for Italy.——Dr. S. J. Kopetzky has accepted an invitation from the Detroit Medical College to hold an otologic clinic during the alumni meeting in May.——Dr. Moses D. Lederman has been elected clinical professor of laryngology and rhinology in the New York Polyclinic Medical School and Hospital.——It is reported that the officials of the town of Brighton, on account of opposition to the action of Dr. William B. Cochran, health officer of the town, regarding the construction of a tuberculosis hospital on the county farm, voted to remove him from office.——The appellate division of the supreme court has ordered Dr. Allan McLane Hamilton, who obtained judgment for $7,000 for professional services in the Thaw case, to prove his claim at a new trial of the case.——Dr. H. A. Bray has been appointed first assistant physician at the Raybrook State Hospital for Incipient Pulmonary Tuberculosis.——Dr. Amasa M. Brown has been appointed junior physician at the St. Lawrence State Hospital.——Dr. Lee W. Thomas has been appointed junior physician at the Central Islip State Hospital.

NORTH CAROLINA

Emergency Hospital to Open.—The Charity Aid Society of Greenville announces that the Emergency Hospital at the Salvation Army Citadel will be opened April 1. The hospital will have the use of five rooms, and members of the county medical society have agreed to give their services free to patients.

Addition to Watts Hospital.—George W. Watts, who gave Watts Hospital to the Durham County Medical Society and the city of Durham, at a cost of $400,000, has decided to add thirty more rooms at an additional cost of $60,000. Work will begin on the annex at once and it is expected to be ready to receive patients June 30.

Case Goes Against Physician.—In the case in the superior court of Charlotte, Mecklenburg county, in which Miss Daisy Long sued Dr. James A. Austin for $10,000 for malpractice for alleged failure to recognize and properly reduce a dislocated shoulder, the jury awarded the plaintiff $1,000 damages. Dr. Austin has appealed the case to the supreme court. The defendant's witnesses brought out the fact that a sufferer from an epileptic attack was not mentally responsible at the time, and the fall in which the injury is alleged to have been received followed an epileptic seizure.

OKLAHOMA

Antivaccination Bill Killed.—The effect of the Stafford Vaccination Bill was nullified by the action of the Senate March 12. The bill originally provided for compulsory vaccination, but Senator Davis put through an amendment providing that there should be no compulsory vaccination, which left the law self-contradictory. The bill finally failed to pass by a vote been received followed an epileptic seizure.

Medical Society Meeting.—At the annual meeting of the Cleveland County Medical Society at Norman, March 16, the following officers were elected: President, Dr. John D. McLaren, Norman; vice-president, Dr. James A. Davis, Norman; secretary-treasurer, Dr. A. C. Hirschfield, Norman; alternate-delegate to the state association, Dr. David W. Griffin, Norman, and censor, Dr. Robert E. Thacker, Lexington.

PENNSYLVANIA

State Board Appointment.—Dr. Robert E. Holmes, Harrisburg, has been appointed a member of the eclectic medical examining board, vice Dr. William H. Blake, Philadelphia, term expired.

Sanatorium Report.—At the annual meeting of the Free Hospital for Poor Consumptives, White Haven, March 14, the institution was shown to be in a better condition than at any previous time in its history, despite the absence of state aid. The secretary's report showed that 1,717 patients were treated during the year, 212 of whom were held over from the previous year. Of these 24 died and 562 were discharged cured, 131 remaining. The results of treatment showed disease arrest in 68 cases, much improvement in 103, and improvement in 276. The cost per patient per week was $9.05. The cost for the entire year was $103,433.61. The resources were $114,693. The following officers were elected at this meeting: President, Dr. Lawrence F. Flick, and managers, Drs. Talcott Williams, Charles J. Hatfield, Daniel J. McCarthy, Joseph Walsh, Richard H. Harte, Frank A. Craig, Henry R. M. Landis and Ward Brinton.

Philadelphia

Jewelry Bequest.—The will of the late Elizabeth P. Hopple provides that the testatrix's jewelry be sold and the proceeds applied to the establishment of a free bed in the children's ward of the Presbyterian Hospital at a cost of $2,000.

Fresh Air Magazine Resumes.—After a suspension of nearly a year, the Pennsylvania Society for the Study and Prevention of Tuberculosis has resumed the publication of its official organ, the *Fresh Air Magazine*, March 17. With assured financial support the society now feels confident that the permanency of this adjunct to its educational work is made certain.

Deaths Deplored by Medical Board.—March 17, at a meeting of the Philadelphia General Hospital's Medical Board, resolutions were adopted deploring the deaths of Dr. Wharton Sinkler and the Rev. Eugene McElhone. Dr. Sinkler was neurologist at the institution from 1888 to 1896. Father McElhone was a priest, who, for 33 years had attended the wants of Catholics in the institution, where he was chaplain. The resolutions were signed by Drs. Frederick P. Henry, Theo. H. Weisenburg and J. Hendrie Lloyd.

Personal.—Dr. G. Betton Massey sailed for Europe March 19.——Dr. James H. Closson, of Germantown, was seriously injured March 14, in a collision between his automobile and a trolley car.——Dr. Alexander C. Abbott has been selected as a delegate to the International Congress of Hygiene and Medicine, which meets in Buenos Ayres, Argentine Republic, next month. He will exhibit statistics and photographs showing the work of inspection of school children as conducted by the Bureau of Health, of which he was formerly chief.

Plans for Home Coming Week.—The Medical Alumni of the University of Pennsylvania will hold their annual reunion in Philadelphia during the Home Coming week, March 28-April 3. The program for the week includes symposia on serum diagnosis and therapy and cardiovascular diseases. The alumni dinner will be held on March 30. On March 29, the celebration of the centenary of the founding of the chair of obstetrics will be celebrated, Dr. Barton C. Hirst being the orator of the occasion. A smoker will be held on the evening of March 28.

WASHINGTON

Hospital Notes.—The Burlington Hospital, three stories in height, is practically completed at a cost of about $20,000. Dr. Orville R. Allen, formerly of Stanwood, will have charge of the hospital.——The new Sacred Heart Hospital, Spokane, which has been under construction for five years, will be opened this month. The building is six stories high, has 240 rooms, of which 100 are for private patients, and will have cost, when completed, about $800,000.

Personal.—Dr. Marion F. Setters, Spokane, charged with conducting the Spokane Cooperative Hospital Association, a one-dollar-a-month-fee institution, and found guilty, is said to have been unanimously expelled from membership from the Spokane County Medical Society at its regular meeting, March 3, for continued violation of the by-laws.——Mrs. Anna Chapman, Woodland, has been elected school director. ——Dr. Spencer S. Howe, Lynden, is reported to be seriously ill with diphtheria.——Drs. William D. Kirkpatrick and Frank J. Van Kirk, Bellingham, sailed for Hawaii, March 5.

GENERAL NEWS AND COMMENT

Congress on School Hygiene.—The third International Congress on School Hygiene will be held in Paris August 2-7. The object of the congress is to afford educators and hygienists and persons interested in the health and vigor of coming generations, an opportunity to become personally acquainted and exchange ideas with those who are doing similar work in other countries. The work of the congress is divided into eleven sections, namely: educational buildings and furnishings; hygiene of residential schools; medical inspection of schools and individual health records; practical measures for actual application; education and physical training; the prevention of contagious diseases in schools—diseases caused by school attendance; out of school hygiene, open air schools; holiday colonies; the teaching staff, their hygiene, their relation with homes and with the school doctors; teaching of hygiene to teachers, scholars and parents; teaching methods and syllabuses in relation to school hygiene; special schools for abnormal children, and hygiene of the eye, ear, mouth and throat. During the congress, excursions and visits to French schools will be organized, and an exhibit of school hygiene will be placed at the disposal of the committee. Dr. L. Dufestel, medical inspector of the public schools of Paris, 10 Boulevard Magenta, is secretary-general of the congress, and Dr. Thomas A. Storey, College of the City of New York, Convent avenue and 139th street, has copies of the circulars relating to the congress, which he will be glad to forward to any who desire.

FOREIGN

Recent Deaths in the Profession Abroad.—Among the members of the profession abroad who have recently died, besides those mentioned elsewhere, are Dr. J. Krannhals of Riga, Russia, for twenty years one of the editors of the *St. Petersburg. medizinische Wochenschrift*, who died from exanthematous typhus at Riga, aged 56. Krannhals was a frequent contributor to medical literature, especially on pseudomeningitis and the tuberculin reactions, and on his deathbed he dictated the conclusion of another article on this last-named subject. ——Prof. S. S. Botkin, of St. Petersburg, body physician to the czar.——Dr. S. Rona, professor of dermatology at Budapest, author of several works on his specialty.

Recent Medical Congresses in Russia.—A letter from Moscow in the last *Medizinische Klinik* states that six medical congresses have been held in Russia since the beginning of the year; the authorities have previously refused to consent to the summoning of medical congresses since their experience with the congress of the national medical association, the Pirogoff Society, whose annual meeting in 1904 started the revolution by its resolutions demanding political freedom for the Russian people as indispensable for physical, mental and moral welfare. The series of congresses this year opened with the first congress for internal medicine. This had a strictly academic character, discussing among other topics, thyroid treatment of obesity, Wagner reporting 160 cases with brilliant results. The tuberculin reactions were also discussed, most of the speakers remarking that the cutaneous technic was instructive only so far as children were concerned; the majority commended the ocular test as useful and harmless. Gastric ulcer was discussed at a joint meeting with the surgical congress. The twelfth congress of physicians and physicists, similar to the German *Naturforscher* congresses, was attended by 5,000 members. No hall could be found in Moscow large enough to accommodate all the members at one time. A veterinary congress followed; one of the resolutions adopted urged that women be admitted to the veterinary colleges. The congress of alienists was held at St. Petersburg, with 275 members in attendance, and this was followed by the antialcohol congress which drew up some drastic resolutions, one condemning the present system of state liquor monopoly which is breeding drunkards and undermining the peasantry, while the amount of liquor consumed is constantly increasing. The authorities here interfered in the proceedings and a few censored resolutions were finally adopted by the few members left in the hall. All of the speakers from the labor groups and two correspondents of "liberal" lay journals were arrested the next day. Some of the labor members were soon released, but all the others are still locked up.

LONDON LETTER

(From Our Regular Correspondent)

London, March 12, 1910.

The Polyclinic

The annual report of the Medical Graduates College and Polyclinic shows that the financial difficulties which, as stated in a previous letter to The Journal, threatened to bring this useful and unique institution to an end are being surmounted. Both in its educational and financial relations, the Polyclinic has had a distinctly successful year. This is evidenced not only by the balance sheet showing a moderate sum on the credit side but by an increase in the number of subscribers from 359 to 470 in spite of the fact that in consequence of the uncertain condition of affairs in the early part of the year many of the subscribers withdrew. The attendance at the clinical demonstrations and lectures has also been large. The number of patients shown during the year was 893. As most of these were cases which had been selected in consequence of their exceptional interest the importance of this figure is greater than might at first appear. The success which the college is able to record has been rendered possible only by the continued support and practical generosity of Sir Jonathan Hutchinson. A legacy of $1,500 from Mr. Alfred Phillips, the late honorary librarian, has also proved of great assistance. In all departments of the college work—clinics, lectures, practical classes, tutorial classes and laboratory investigation—there has been increased activity. New classes have been instituted in the practical use of the cystoscope and sigmoidoscope, the administration of anesthetics, and the medical application of massage and electricity. In connection with the laboratory there has been established a department for preparation of vaccines. It differs from other postgraduate schools in that it does not draw its teachers from only one hospital but from the entire United Kingdom. The Hutchinson Museum of portraits of disease, collected by Sir Jonathan Hutchinson, offers an opportunity for study comparable only to that of the famous St. Louis Hospital of Paris. Though the skin diseases are principally illustrated, unlike the latter institution, every department of medicine which lends itself to pictorial illustration is represented. Its founder has during his long career ever been the great apostle of the pictorial representation of disease and of clinical museums, both for purposes of teaching and investigation, and his lifework shows their great value.

The Institution of a Diploma in Psychiatry

The institution of a diploma in psychiatry is under the consideration of the Royal College of Physicians and other examining bodies to whom it has been suggested by the committee of the Medico-Psychological Association of Great Britain and Ireland. It has long been felt that there is no adequate systematic instruction in psychiatry in Great Britain. Young physicians on their appointment as medical officers to asylums have to face work and problems of which they have had no previous knowledge and in preparation for which they can obtain no training. Lectures on psychologic medicine and pathologic laboratories have been established here and there, and in one or two universities chairs of experimental psychology have been founded but there is no systematic course of instruction and no recognized diploma. The Medico-Psychological Association considers that the time has arrived when such a course and diploma should be established in the principal medical schools, and that the institution of a diploma would impose a high standard of acquirement on the officers of asylums, stimulate the scientific study of insanity, and have an effect in widening and deepening our knowledge of the subject comparable with the effect produced in tropical diseases by the institution of a diploma in this subject. The association also considers that the minimum period of postgraduate work to obtain the diploma should be one year; that the subjects should be divided into (a) compulsory (b) optional; that in the former should be included (1) the anatomy, psychology, and pathology of the nervous system; (2) psychology, normal and morbid; (3) clinical pathology; (4) clinical neurology; (5) psychiatry—systematic, clinical and medicolegal. The optional subjects suggested are: (1) experimental psychology, (2) biochemistry, (3) bacteriology, (4) comparative anatomy and physiology of the nervous system, (5) eugenics. It is suggested that only one optional subject should be required. At a meeting of a comitia of the Royal College of Physicians these proposals were discussed, and Dr. C. A. Mercier, president of the Medico-Psychological Association, moved a resolution that a committee be appointed to settle the conditions under which a postgraduate diploma in psychiatry shall be granted. He said that it was an undoubted deplorable fact that psychiatry was lagging behind other departments of medicine, and had not participated as much as they had in the striking advances of the last few decades. He admitted that this was in part due to the inherent difficulty of the subject, but he also attributed it largely to the fact that the junior staff of asylums with abundant leisure and opportunities for research were deterred from undertaking it by lack of incentive. No scientific work that they might do in any way bettered their position, increased their reputation with their employers or assisted them to promotion. The institution of a diploma could scarcely fail to have the effect that it had in the case of public health of educating public bodies into appreciating that special knowledge was necessary for these responsible posts. The resolution was supported by other eminent psychiatrists. It was opposed by Dr. Norman Moore on the grounds that if it is in the interests of the public that physicians should know something of psychiatry, that knowledge should be obtained by adding to the medical curriculum, and not by depriving any of one of the ways for earning a living. An amendment appointing a committee to consider the subject was adopted. The struggle for psychiatry to obtain recognition is only a repetition of what has happened in the case of the other specialties. The more conservative minds in the profession will no doubt obstruct the reform, but with success only for a time.

The Sleeping Sickness Commission

Col. Sir David Bruce, the head of the commission despatched in September, 1908, by the government under the direction of the Royal Society to investigate sleeping sickness in Africa has returned on the termination of his mission. The headquarters of the mission was at a place called Mpunu, a desolate and remote spot six miles from the northern shore of Lake Victoria Nyanza, and about the same distance from a great concentration and isolatión camp where hundreds of the victims of sleeping sickness were taken to end their days. The ravages of the disease are shown by the fact that on the peninsula on which the laboratory was erected there were formerly 50 churches, but all except one have now been closed. The discovery made by Dr. Klein in German East Africa that the tsetse fly can remain infective for several months or even much longer has vitiated the theory that infected zones cleared of their inhabitants can after a brief period be repopulated by healthy persons. In the fly area, the most energetic steps have been taken to remove all the inhabitants. One island which formely had a poulation of 22,000 was cleared of 4,000 natives—all that were left by the ravages of the disease. The population of the lake shores had been reduced to one-fifth, and all these have been moved. Strips of land in the neighborhood of the landing places have also been cleared and all the native canoes destroyed. In consequence, no fresh cases of sleeping sickness are occurring, and it may thus be inferred that the epidemic has been stamped out. Further investigation is being made to see how long the fly remains infective

PARIS LETTER

(*From Our Regular Correspondent*)

Paris, March 11, 1910.

A Manifesto in Regard to the Approaching Concours de l'Agrégation

After the *concours de l'agrégation* of 1908, a committee formed by various professional organizations (*Union des syndicats médicaux de France, Comité de vigilance du Congrès des praticiens*, etc.) presented to the authorities a memoir summing up the protest of the medical profession (The Journal, March 27, 1909, lii, 1046). This memoir having received no reply and the same system being maintained for the *concours* which is soon to be held, the committee has appealed to medical opinion and has published a manifesto in which the defects of the present system of the *concours de l'agrégation* are reviewed. Pedagogically, the *agrégation* is the consecration of the supremacy of theoretical over practical instruction, for the *concours* is based on theory. Scientifically, according to the manifesto, the *agrégation* is not merely useless but injurious; useless because the preparation for it is merely bookish; injurious because such preparation discourages scientific research. The *agrégation*, moreover, tends toward the division of the medical profession by putting all instruction in the hands of a closed caste.

The French League for Physical Education

Under the honorary presidency of Prof. Charles Richet and the acting presidency of Professor Gilbert there has just been founded in Paris a League for Physical Education, which proposes, among other things, to make scientific researches into the methods to be employed in gymnastics and in sports, so that movements which, for lack of precise rules, are at present either unused or abused may be prescribed with definite precision. The league proposes also to give instruction by lectures, by practical courses, by the organization of festivals, contests, walks and excursions, by the establishment of gymnasiums, etc. It will give particular attention to the physical education of women and girls, which has been so much neglected up to the present. For this purpose it will have sections devoted to feminine sports. A scientific committee composed of all well-known persons concerned with physical education will ultimately be formed. The league has opened a competition the object of which is to obtain a simple, short and practical book on physical education, suitable for every one, children and adults, men and women.

The Society for the Protection of Infancy

During the recent general assembly of the Society for the Protection of Infancy, Dr. Porak, who presided, related the history of the society since its foundation in 1865. The object of the society is to encourage and to protect maternal breastfeeding, to preserve infants at the breast from the dangers which threaten them, to protect children against abandonment, neglect, and bad treatment, and, in short, to popularize in families the principles of the hygiene of infancy. Since its foundation, the society has expended 1,566,710 francs (about $300,000); more than 53,000 families have received about 1,092,000 francs (about $200,000).

Jubilee of Dr. Gellé Senior

Germany and Austria having recently honored the deans of otology, Politzer, Lucae and Schwartze, the pupils and friends of Dr. Gellé senior, one of the pioneers of otologic science, believed that the moment had come to celebrate his jubilee and to give sympathetic recognition to the merit and the usefulness of his long and fruitful labors. A committee composed of Professors Bouchard, Dastre, S. Duplay, Gley, Laveran, F. Raymond, and otologists like Professor Moure, and Drs. Bonnier, Castex, Lermoyez and Sébileau, decided to open a subscription for a medal for Dr. Gellé.

A Triumph of Empiricism

The minister of labor has just submitted for examination by the commission on secret remedies of the Academy of Medicine a treatment for anthrax recommended by an empiric. This treatment, which would seem to consist simply of cauterization by caustic potash, is much in favor among workmen in Mazamet, department of the Tarn, who are much exposed to anthrax because they handle wool. These workmen refuse to consult physicians or to submit to any other treatment.

Discontent Among Private Nurses

Much discontent has been felt for some time among private nurses and masseurs. They complain that they are exploited by the employment agencies which supply nurses. According [illegible]hem, these establishments ask from 200 to 300 fra

($40 to $60) a month from families, which employ the nurses, and pay their employees only 50 to 60 francs ($10 to $12). When they employ outside nurses they demand 50 to 60 per cent. of the salaries paid.

Unwarranted Use of the Name of Dr. Huchard in a Pharmaceutical Advertisement

In the last number of the *Journal des Praticiens*, Dr. Huchard protests energetically against the unwarranted use of his name by manufacturers in Mexico who have put out pharmaceutical preparations to which they have given the name of "Dr. Huchard's Pills." In advertisements in the Mexican lay press, praising this preparation under the title of "Radical Cure of Maladies of the Digestive Organs," one reads that "the learned Dr. Huchard of Paris, inspired by the studies of his colleagues and his own experiences in hospitals and laboratories, has finally solved this complicated problem by inventing the celebrated pills which bear his name, and which, although they have been used by thousands of patients, have never once disappointed expectations. . . . Dr. Huchard, who can never be sufficiently praised, has composed two formulas; gilded pills for cases with diarrhea; silvered pills for cases without diarrhea."

Dr. Huchard intends to write to the French minister in Mexico about the matter.

Election of Two National Associates to the Academy of Medicine

In its session of March 8, the Academy of Medicine elected as national associates Dr. Poncet, professor of clinical surgery at the Lyons college of medicine and M. Balland, former head pharmacist of the army, well known by his work on alimentary substances.

VIENNA LETTER

(From Our Regular Correspondent).

VIENNA, March 4, 1910.

Investigation on the Dwellings of Tuberculous Patients

Dr. Burkhard has recently been investigating the condition of 250 dwellings inhabited by tuberculous laborers in an Austrian city. The 250 lodgings had only 487 sleeping-rooms. The number occupying each lodging varied between 2 and 13. Sometimes 6 to 8 persons lived in a lodging consisting of one room only. The dangerous conditions are vividly illustrated by the fact that of the 292 positively tuberculous persons, 93 slept with other persons in one bed; among those thus exposed to infection were especially children. Bedridden patients were often found accommodated in the kitchen (in 25 per cent.) or in a dark corner of the room (18 per cent.). There was no knowledge how to deal with tuberculous sputum. Children were found playing with sawdust from a spittoon used by tuberculous persons.

The publication of this painstaking exact investigation has caused much excitement, but it shows where the fight against phthisis has to be pressed hardest. Similar conditions prevail in all cities where tuberculous laborers live. The primary source of infection consists of overcrowding and slums.

Unveiling of a Statue of Professor Jaeger

The famous ophthalmologist, Professor Jaeger von Jaxtthal, who died in 1884 and who for eighteen years was the foremost eye surgeon of Europe, was honored a few days ago by the erection of a life-sized statue in the aula or hall of the University of Vienna. Professor Fuchs delivered the customary speech on this occasion. Jaeger was the son of a famous ophthalmologist; was the grandson, on his mother's side, of the famous ophthalmologist Beer, who had been the first (and only) eye surgeon of Europe of his time, and was married to the daughter of Arlt, who was considered the best eye diagnostician in the seventies of the last century. One of the best works of Jaeger was the "Atlas of the Fundus Oculi," which has not been surpassed yet as regards its lifelike depictions of the conditions of the retina.

Sale of Radium Permitted in Austria

The sale of radium salt has been now authorized in this country, but the government has taken the trade into its own hands. The price of *1 mg. (1/60 of a grain) has been* placed at 400 kronen, or $80, but smaller quantities may be purchased. Only the barium chlorid of radium can be had, in a strength of 5, 10 and 25 per cent. It is put up in small brass capsules, one wall of which consists of lead; here the salt is deposited and an opening covered by a mica plate permits the use of the radium for therapeutic applications, without opening the cell. A hall-mark certifies the strength and weight of the substance. Already many physicians have availed themselves of the opportunity of obtaining radium cells.

Pharmacology

[CONTRIBUTION FROM THE CHEMICAL LABORATORY OF THE AMERICAN MEDICAL ASSOCIATION.]

MICAJAH'S MEDICATED UTERINE WAFERS

W. A. Puckner and W. S. Hilpert

Evidently touched by the generosity of the manufacturer in sending him a sample and literature, but not too favorably impressed by the claims made for the preparation referred to, a correspondent writes:

> I enclose a valuable sample and literature just received. Such a palpable humbug as Micajah's Uterine Wafers would hardly seem to need notice were it not probably true that many practitioners habituated *to the use of samples are still influenced* by the glowing accounts of cures wrought; especially when attested by such a name and title as "Elmore Palmer, M.D., Ex-President Western New York Medical Society." This secret gynecologic medicament is recommended for anything from "Pruritis Vulvæ," "Enlargement of the Womb," "Displacements," "Cystocele and Rectocele," to the "Menopause."
>
> Following the definition that by her "stomach" a woman means anything from her chin to her knees, the ex-president with truly noble impartiality has with the wonderful Micajah wafers wrought lightning cures all the way from "stone-bruise" of the heel to nasal polyp and influenza, and some of them are male patients, *too.*

With the foregoing as an impetus to investigate the nature of this much advertised nostrum, the wafers were submitted to analysis by the Association laboratory. The report follows:

LABORATORY FINDINGS

Trade packages of the wafers purchased on the open market bear the name of the preparation and that of the manufacturers, Micajah & Co., Warren, Pa. The label states that the nostrum is a:

> "Disinfectant, astringent and local alterative of the greatest virtue. *A remedy for the local treatment of the diseases of women.* Inflammation, engorgement and prolapse of the womb, vaginitis, leucorrhea, menstrual derangements and the disturbances incidental to the *menopause. Also highly recommended for affections* of the mucous membranes in general, particularly those of the nose, the throat, the rectum, and for gonorrhea, cystitis, etc."
>
> "This box contains wafers for three months' treatment."
>
> "Price per box $1.00."

The box contained 25 tablets, and a circular entitled, "Hints on the treatment of diseases of women," in which directions for the treatment of many diseases are given. It ends with a paragraph which contains the following statement:

> "There is *no doubt* that the field of usefulness of Micajah's Wafers can be indefinitely enlarged by the ingenuity and therapeutic skill of the physician."

Much of the advertising "literature" is in the form of leaflets, brochures and small pamphlets full of testimonials by physicians.

Micajah's uterine wafers as found on the market are white, hexagonal tablets, odorless and possessing an astringent taste. The wafers are soluble in water with extreme difficulty. Hot hydrochloric acid and alkali hydroxids dissolve the powdered tablets readily, leaving a slight residue which under the microscope and by physical tests was identified as lycopodium.

The acid solution of the wafers responded to qualitative tests which indicated the presence of potassium, sodium, aluminum, sulphate, borate and a mere trace of a fatty material. Quantitative estimation of boric acid, aluminum, sulphate, sodium and potassium were made, which indicated that Micajah's Uterine Wafers consist of alum more or less anhydrous or "burnt," boric acid and borax in approximately the following proportions:[1]

Alum, dried	59.86 per cent.
Borax, dried	15.62 per cent.
Boric acid	5.67 per cent.
Water of hydration	18.85 per cent.

The average weight of the tablets is 0.7791 gm. (11.8 grains) and allowing for the fact that the quantity of water present in commercial exsiccated alum varies, each tablet would contain approximately 0.4986 gm. (7.8 grains) burnt alum; 0.2337 gm. (3.6 grains) crystallized borax, and 0.0467 gm. (0.7 grain) boric acid.

COMMENT

Judging from the "literature" that goes with the packages of this nostrum, *one might* imagine that it was put up absolutely for the layman, but this is not the case. It is advertised only in medical journals and not directly to the public; it is not necessary, for every physician who prescribes it at the same time places in the hands of his patient advertising matter intended to influence that patient—and it usually does. As a result this preparation is being bought by the public direct; to what extent we do not know, but physicians are responsible for it. Probably if physicians realized that the same interests that control Piso's Consumption Cure also control Micajah's Medicated Uterine Wafers they would not be so ready to act as the unpaid agents for the concern.

---

[1] The details of the analysis will be published in the annual report of the laboratory.

That such simple astringents and feeble antiseptics as alum, borax and boric acid could have such remarkable curative effects on uterine diseases is absurd. The serious aspect of the matter is, that, by the encouragement given them in the advertising literature to treat themselves, women may neglect proper surgical or medical attention in the early stages of serious diseases such as cancer or dangerous pelvic infections, until they get beyond the hope of proper management. But when nostrum promoters urge the use of such inefficient remedies in the treatment of gonorrhea, it is time to look at the matter seriously. Considering the vital social significance of the venereal diseases, the employment of useless remedies can only favor the spread of these infections, which cause such a large proportion of the diseases which afflict women particularly.

The medical profession for the most part has become mentally calloused to the exaggerated claims of the nostrum makers and does not make sufficient effort to condemn them. There may be some physicians, however, who use such preparations as these wafers in their practice, as is indicated by the circulars, wherein the manufacturers suggest that their "usefulness can be indefinitely enlarged by the ingenuity and therapeutic skill of the physician." It is only occasionally that a physician voices his indignation as to these humbugs, as in the case of the physician whose letter is quoted above.

SAL HEPATICA

This wonderful mixture, according to the advertisements, is "a combination of the tonic, alterative and laxative salts similar to the celebrated 'bitter waters' of Europe, as determined by actual chemical analysis of these waters, and fortified by the addition of lithia and sodium phosphate"—a description, by the way, that is used *verbatim et literatim* by the A. D. S. in describing its "Hepatic Salts."

As usual, in inflicting this remedy on the public, the manufacturer makes use of cast-off medical theories and unwarranted claims. The marked absurdity of some of the statements indicates that they are intended for the lay public. Surely no nostrum-maker would suppose that he could delude even the most credulous portion of the medical profession into believing the statements made in the advertisements concerning sal hepatica, namely, that the same remedy is a uric-acid eliminant, hepatic stimulant, a specific for gout, rheumatism, cirrhosis of the liver, Bright's disease, gravel, tuberculosis, struma, marasmus, dyspepsia, infantile fluxes, etc.

The following analysis of "Sal Hepatica" was published in the *Druggists Circular*, February, 1909, p. 78:

Sodium chlorid	13.05 parts
Sodium sulphate	26.27 parts
Sodium phosphate	29.80 parts
Sodium bicarbonate	18.00 parts
Lithium phosphate	0.04 part
Citric and tartaric acids, to make	100.00 parts

Our old friend lithium is added, undoubtedly, to influence the few physicians who still accept the discarded theory regarding the solvent effect of lithium salts on uric acid. Such physicians must be easily influenced if they can believe that 4/10,000 parts of lithium would have any therapeutic effect!

Thus once more the medical profession is asked to indorse a nostrum consisting of a mixture of simple saline laxatives such as any physician can prescribe and any druggist prepare, and to sanction the blatant advertising of the mixture as a specific in such grave maladies as cirrhosis of the liver and Bright's disease. This advertising has already made the drug known to the laity, who see in the shrewdly chosen name an indication of the use of the nostrum in liver disease and that undefined but favorite malady of the public, "biliousness."

The abuse of saline cathartics by the public is an evil deserving of serious attention. Rightly or wrongly, the laity fear constipation, and naturally take what they are taught to believe is the cheapest and simplest course for its relief, self-drugging by means of saline cathartics or the extensively advertised purgative mineral waters. This habit is responsible for much of the distressing spastic constipation that exists, and its accompanying neurasthenia. The advertisement and sale to the laity of such a nostrum as "Sal Hepatica" can only increase these evil results and the physician who aids and abets the evil by using the preparation should reflect whether he is thereby not only encouraging a fraud on the public, but also, what is even worse, helping to impair the public health.

Correspondence

Cecostomy vs. Appendicostomy

To the Editor:—The very interesting and instructive article on "A New Method of Appendicostomy," by Dr. Pettyjohn, in The Journal, March 12, 1910, carries with it some incidental confirmation of my contention (The Journal, March 5, 1910), that in certain cases cecostomy is to be preferred to appendicostomy. Thus Dr. Pettyjohn speaks of "cases in which the mesoappendix is too short or too narrow to permit the appendix to be drawn out of the abdomen;" he likewise very properly urges precaution "not to interfere with the blood supply of that portion of it which is to form the canal;" he tells us furthermore that "considerable swelling always occurs in the walls of the appendix;" that "it is much easier to open the appendix and introduce the catheter at once than to wait;" he alludes to conditions "requiring considerable stretching of the appendix to bring it to the surface" and admonishes us that "such a result is most reprehensible and may cause stopping of the blood supply with a resultant sloughing of the appendix."

My observations and the recorded experience of many other operators in these particulars are in entire accord with those of Dr. Pettyjohn. They have indeed so impressed me that, in the absence of special indications, I have been induced to adopt cecostomy rather than appendicostomy as the operation of choice. The mere fact that the presenting pouch of the cecum lies against the abdominal wall to which it can be attached practically *in situ naturalis* without present or subsequent traction and consequent pain is an additional reason of great weight in determining my operative policy in these cases. Too much weight has, I am sure, been given to the argument that we need a tube, the appendix is a tube, therefore use the appendix. In no case is it a good tube to begin with and in the majority of these cases it is no tube at all to end with. Charles A. L. Reed, Cincinnati.

The Davis Memorial

To the Members of the American Medical Association:—It is desired that every reader of this appeal consider himself a self-appointed member of the committee to procure funds for the Davis Memorial. The Association itself has set the example by appropriating $5,000, provided a total of $25,000 be raised for this worthy object. Each state is represented by an appointee on the committee for this purpose. A considerable sum of money has already been raised and one or two states have contributed more than their apportionment.

Of course the completion of this work is not due to a lack of appreciation of the services and character of the founder of our great Association. Perplexed in the busy routine of daily demand the privilege of the recognition has simply been forgotten. Your committee would have every member of the medical profession of America interested and represented in this memorial. A little work done in each district and state society and the service is completed. Let the money be forwarded through your representatives directly to the treasurer of the Association, Dr. Frank Billings, 100 State street, Chicago. Let us join hands and hearts in the completion of a work already too long delayed.

HENRY O. MARCY, M.D., Boston, Chairman.

A Department of Public Health

CINCINNATI, March 19, 1910.

To the Editor:—In THE JOURNAL, March 19, just received, appears some correspondence between myself and Hon. Robert L. Owen of the United States Senate, regarding proposed legislation looking toward the establishment of a Department of Public Health. In the second paragraph of my letter, on page 985 of THE JOURNAL, appears a reference to the action taken by the Legislative Conference held at Chicago, March 2, 1910. My letter was written to Senator Owen on March 10, at which time I had not seen the official minutes of the Conference. The minutes which have reached me only to-day show that two references were made to this subject.

1. The report of the Committee on Federal and State Regulation of Public Health reads as follows: "We suggest that a bill be passed that will give recognition of the health interests of the country in the title of a department, and that within that department there be organized an efficient bureau of health to consist of all present public national health agencies." This report was adopted.

2. The Committee on Conclusions and Plans of Action presented, as its fifth resolution, the following:

> *Resolved,* That the Conference heartily endorses the position taken by the President in his message to Congress in regard to national health legislation, and urges on Congress the passage of legislation looking toward such ends.

This resolution was also adopted.

I have written to Senator Owen, correcting my letter of March 10, in this respect. In the interests of accuracy, I ask that you will kindly give this letter space in the Correspondence Department of THE JOURNAL.

CHARLES A. L. REED.

The Late Dr. James Sykes and a Cholera Epidemic

To the Editor:—Mention of the name of James Sykes in the list of medical dead printed in THE JOURNAL, March 19, recalls the fact that the deceased physician had near relations to a tragedy which, perhaps, has no equal in modern medico-military history—one, possibly unique in somberness—and, as Dr. Sykes aided me in getting together facts pertinent thereto, space is asked for a statement of this event in order that his memory may be honored, and that a younger generation of physicians may know of the power of Asiatic cholera to destroy when opportunity is afforded.

My attention was called to this occurrence in 1894 by seeing a monument, in the burying-ground of the St. Louis Quarantine Hospital, just below Jefferson Barracks, erected in memory of one hundred and seventy-five non-commissioned officers and soldiers of the Fifty-sixth United States Colored Infantry who died of cholera in 1866. The inscription seemed so startling as to invite inquiry; this was undertaken, and the collected facts were read before a local medical society and published in the *New York Medical Journal*, March 30, 1895.

The surgeon-general of the Army was appealed to for such information as was on record and this, though scanty and of non-medical character, was promptly supplied. Through this and other means, it was found possible to get in touch with some of the surviving officers; Dr. Sykes was the assistant surgeon of the regiment.

An outline of this tragical event is given in the following:

> Early in August, 1866, the regiment in question was on duty in Arkansas, five companies being stationed at Duvall's Bluff, and the remainder of the command, with regimental headquarters, was at Helena.
>
> Being ordered to proceed to Omaha via St. Louis, the command, seven hundred and eight strong, assembled at Helena, and the five companies that had been at Duvall's Bluff embarked on board the steamer *Continental* on the evening of August 9. The remainder followed on the *Platte Valley* the next morning.
>
> The colonel states that the command had been unusually healthy during the summer, and the surgeon confirms this, saying that the regiment was in the best of health at the time of embarking.
>
> No medical officer accompanied the command on this fatal journey, which has but one known parallel in American military-medical history, and perhaps few anywhere else.
>
> Within a few hours after the boats swung out into the current of the Mississippi River mischief began (the first patient was left dying on the wharf at Memphis), and by the time the *Continental* reached Cairo she had on board thirteen corpses and between fifty and sixty cases of cholera, all belonging to this regiment. More than fifty men of this command died on this boat before St. Louis was reached, the second boat not suffering so severely, but hardly a soldier in the entire regiment escaped an attack of the disease.
>
> About a week after these troops left Helena the commander reported the deaths to that time among his men as one hundred and thirty-nine, but the end was not reached until the number recorded on the monument had perished, if, indeed, that number is correct, as it appears from the War Department records and information from other trustworthy sources, that the mortality in this body of men from this one cause was nearer one hundred and ninety than one hundred and seventy-five—a loss of more than one in every four in the command.

In a personal letter dated April 2, 1894, Dr. Sykes commented on certain features of this outbreak, as follows:

> I was informed at the time that the most infected boat had a quantity of raw sugar going to the refineries, and that the soldiers, being on the boiler deck, burst open several hogsheads of it, and ate as only colored men can. My own theory is that the soldiers either took the cholera microbes from Helena or else these were already on the boat, and then, gorging themselves with raw sugar, allowed the pestilence to get in its deadly work. The fact that but very few officers took the disease at all, and they in a light form, would seem to indicate that it was something in the diet, rather than the water, as all used river water alike. But one officer died. (Lieutenant Brooks), and he from a relapse occurring after he had recovered so far as to take a leave of absence to visit his family living in St. Louis. After the troops arrived at St. Louis they were removed to quarantine, and the cholera became general among all the companies. The above is from memory, and while I doubtless have forgotten some facts, the narrative is substantially correct.

GEORGE HOMAN, M.D.

Miscellany

The Effects of X-Ray Treatment on Leucemia.—In myelogenous leucemia and in chronic lymphatic leucemia H. Pribram and H. Rotky (*Ztschr. f. exper. Path. u. Therap.*, 1909, vi, 75) found that the *x*-ray treatment was followed by an improvement in both the general systemic condition and in the clinical condition of the blood. In 4 cases of myelogenous leucemia, in which the spleen was subjected to intensive treatment with the *x*-ray (the remainder of the abdomen being protected by the Jaksch silver plate) a marked improvement in the general condition as well as in the blood-picture, with little or no damage to the skin, was the result. In 2 of these cases the total number of leucocytes quickly diminished, while in the other 2 the reduction of the number of leucocytes was more gradual and less complete. In all the percentage of mononuclear leucocytes decreased while that of the polynuclear neutrophiles rose. In 1 of these cases, through a reduction in the eosinophiles and basophiles and a marked reduction in the lymphocytes, the blood-picture soon approximated normal. Moderate intermittent exposures of the surface and exposure of the bones to *x*-ray were followed by less beneficial results. In 1 case of chronic lymphatic leucemia intensive treatment of the region of the affected glands soon reduced the total leucocyte count to normal, but did not affect the percentage of the different types of leucocytes. The total number of red blood corpuscles, of nucleated red blood corpuscles and the total hemoglobin content of the blood were not affected by the treatment in either of the 5 cases. In the myelogenous leucemia, during the reduction of the number of leucocytes, there was observed an increase in the total output of nitrogen, uric acid and phosphoric acid, which persisted for some time after the leucocyte count reached the minimum. In 1 case of advanced acute lymphemia *x*-ray treatment gave no beneficial results.

Treatment of Rupture of the Uterus.—E. Scipiades reports a series of 97 cases of rupture of the uterus all treated according to the same principles during the last 25 years at the Budapest clinic, the only unbroken series of the kind on record, he remarks. His communication on the subject is published as No. 553 of the *Sammlung klinischer Vorträge*. In 66 cases of complete rupture, 34.92 per cent. of the women recovered, including 40.38 per cent. treated by what he calls "exact tamponing," while 44.95 per cent. recovered in the cases without complicating injury of the bladder. The proportion of recoveries was 87.5 per cent. in the 8 women with complete rupture, free from complications, tamponed and removed to the clinic two days after delivery. These figures, he asserts, confirm assertions in favor of conservative measures. After the urine has been drawn, the child is delivered by the vaginal route, with the operative technic deemed advisable. As soon as delivery is complete, the assistant holds the uterus firm in its normal position by pressure from without, while the ruptured wall and, in case of atony, the uterine cavity itself, are packed loosely with iodoform gauze, the vagina is also packed tight and a compressing bandage applied to the abdomen. This is what he calls "exact tamponing." Then saline infusion, ergot and analeptics are used as indicated and the woman is left quiet, to rest, with an ice-bag applied to the abdomen. All this has to be done on the spot, with no attempt to remove the patient. Any attempt at removal just before or after delivery is liable to influence the course of events most unfavorably. The woman is left undisturbed for two days at least, and if possible for a week, the tamponing being undisturbed during this interval unless interference is compelled by increasing or constantly high temperature. She is then removed to some institution for further care. The tampon is here removed and a glass drain introduced, replaced by a rubber drain after six or eight days. Cautious vaginal douches with an antiseptic solution and the necessary local and general measures are continued until the rupture has entirely healed. In case operative interference becomes necessary, partial or total hysterectomy is the rule.

Syphilis and Insanity.—A. J. Rosanoff and John I. Wiseman have tested the Wassermann and Noguchi reactions in a number of patients suffering from the different forms of insanity and report their results in the January issue of the *American Journal of Insanity*. They summarize on the basis of their results the relationship existing between syphilis and insanity as follows: "1. The regular absence of lymphocytosis, of the Wassermann reaction, and of the butyric acid reaction in psychoses with a basis of arteriosclerotic disease known to be the result of old syphilitic infection indicates that these conditions are to be regarded as sequelæ of syphilis, and that the syphilitic process itself is in cases of these conditions already extinct. 2. In general paresis either the Wassermann reaction or Noguchi's butyric-acid reaction is invariably found—and most frequently together; any doubt of the essential dependence of general paresis on syphilitic infection can no longer be entertained. 3. Inasmuch as the Wassermann reaction and the butyric-acid reaction seem to indicate syphilis only when it exists in an active or potentially active form, their regular occurrence in general paresis would tend to prove that that disease is a manifestation of active syphilis, of activity of the *Spirochæta pallida;* while the evidence for this view is not yet complete, it is sufficient to justify its being used as a basis of therapeutic essay. 4. In no other common psychosis does either the Wassermann reaction or the butyric-acid reaction occur with any regularity or even with special frequency; the relation of syphilis to these psychoses is that of a complication by accidental coincidence. 5. From the standpoint of diagnosis, cytologic examination of the cerebrospinal fluid is an indispensable aid in the practice of psychiatry; with the further aid of the Wassermann reaction and of Noguchi's butyric-acid reaction, the diagnosis of general paresis can be either established or excluded with practical certainty." The authors admit that the view that paresis is a manifestation of active syphilis cannot yet be considered as absolutely established, though the constant reactions to the Wassermann and Noguchi tests strongly point that way. The essential link in the chain of evidence—the finding of the spirochete—appears to be still lacking, and until that is supplied we shall still have to speak of parasyphilitic infection, whatever that may mean.

Peculiar Hereditary Anomaly of the Hair and Nails.—In 1894, C. Nicolle and A. Halipré described a peculiar condition of the hair and nails in a large number of the members of a certain family at Rouen. In the *Bulletin of the Society of Medicine of Rouen* for 1908, recently issued, A. Hebert and A. Halipré describe the case of a girl belonging to this family and give some details of the prevalence of the anomaly. The patient, who was a girl of 12, had always enjoyed good health and entered the hospital for impetigo of the face. In general, the examination revealed normal conditions except with reference to the hair and nails. The hairs of the eyebrow were very scanty and entirely colorless. The lashes were scanty and blond; the iris was blue. The skin of the forehead presented scanty downy hairs; the cheeks were absolutely smooth, but on the chin and upper lip were a few downy hairs. The hairs of the head were scanty, short, about 2 cm. (0.8 inch), very small and white; they pulled out very easily, even in tufts, without breaking. It was quite difficult to determine the line of implantation of the hair on the forehead where they could scarcely be differentiated from the down. On the temples the line of demarcation was plain. The hairs on the vertex and the part adjoining the forehead were thinner than on the rest of the scalp. The nucha and the parts above and behind the ear presented only scanty down. The scalp was white and of a uniform pigmentation. There was no development of hair on the rest of the body except some down on the pubis and the lower abdominal region. The terminal phalanges of the hands and feet were enlarged so as to appear clubbed; the nails were hypertrophied, much thicker than normal, smooth and friable at the end, where they were irregularly broken. Their free border was dark, irregularly striated and about 2 mm. thick. The rest of the nail was normally colored and the cutaneous fold around the nail. The occurrence of this peculiarity has been traced backward to the sixth generation and the anomaly appears to have originated at Rouen. Altogether among 80 known descendants 52 have been affected, 28 males and 24 females. So far the affection has never skipped a generation to appear in the following. In certain families all the members were attacked; in others the boys are exclusively the victims, the girls being normal; in still others one child of two or three was affected independent of sex. The heredity appears to be governed by no law. It is hard to say whether the lesion tends to disappear, for if it spares certain children of one branch of the family it attacks all of those of a neighboring branch. There is no ground for incriminating syphilis or leprosy and the etiology of the anomaly remains entirely unknown.

Industrial Diseases: "Let Us Open Our Eyes."—The second international congress for industrial diseases, which is to be held at Brussels, September 10 to 14 this year, is rousing the profession in Belgium to pay greater attention to occupational diseases. The *Gazette Médicale Belge,* in a recent editorial with the above title, *Ouvrons l'Oeil,* urges physicians to begin to collect data for this new science, especially those who have anything to do with patients suffering from industrial diseases. The physician is the expert and should be the leader in this phase of sociology; it is incumbent on him in particular, as his material interests are so directly involved. The social legislation in Belgium, as in Germany, was conceived and wrought out without the aid of the profession, although almost all the burdens of it is borne by medical men. It is for their direct material interests to make their influence felt in such questions, not to mention their scientific interest. Professional inertia and clinging to old routine have wrought dire trouble for the profession where this social legislation has been introduced. In this new science of industrial diseases physicians must take the lead in every line. "Zealous cooperation, careful study of individual cases, in local, state and international associations, and of all the questions involved in industrial diseases will not only serve the interests of the public, but will prevent physicians being made packhorses for the social legislation which seems to be looming up in every land."

Humbug Medicines.—With this title R. von Post publishes in a Swedish medical journal an appeal to all to refrain from prescribing or giving other countenance to the unnecessary and more or less fraudulent remedies which the manufacturers present for the approval of the profession. Even if it happens that one or the other of these proprietaries may possibly have some value, their price is generally out of all proportion to their usefulness or value; the harm they do outweighs any good. He pleads that the physician should not lend his name and his authority to support these commercial undertakings. The *Nordiskt medicinskt Arkiv* comments approvingly on his words, saying that it is the rare exception when a testimonal or other support from the individual physician of these proprietaries is useful or ethically correct. The really valuable remedies scarcely ever obtain recognition by way of display advertisements with testimonials from mostly obscure men. The physician, the editorial adds, acts best for his own reputation and for that of the profession at large and for the interests of the public by making it a principle to refrain from writing testimonials, and thus he will avoid being mixed up in this display advertisement business. Really good remedies do not need this advertising, and the bad and unnecessary ones should not get the support of the profession.

Society Proceedings

COMING MEETINGS

Alabama, Medical Association of State of, Mobile, April 19-22.
Am. Laryn., Rhin. and Otol. Society, Washington, D. C., April 28-30.
Arizona, Medical Association of, Phoenix, April 20-21.
California, Medical Society of State of, Sacramento, April 19-21.
Conf. State and Prov. Bds. of Health, Washington, April 28-29.
District of Columbia, Medical Association of, Washington, April 26.
Florida, Medical Association of, Jacksonville, April 6-8.
Georgia, Medical Association of, Athens, April 20-23.
Maryland, Med. and Chirurgical Faculty of, Baltimore, April 26-28.
Mississippi State Medical Association, Oxford, April 12.
South Carolina Medical Association, Laurens, April 19-21.
Tennessee State Medical Association, Memphis, April 12-14.

MEDICAL SOCIETY OF THE MISSOURI VALLEY

Twenty-second Semi-Annual Meeting, held at Omaha, March 17-18, 1910

The President, Dr. A. B. Somers, Omaha, in the Chair

Psychotherapy in Relation to the General Practice of Medicine and Surgery

Dr. Henry S. Munro, Omaha, discussed psychotherapy in the field of preventive medicine; in the domain of psychophysiologic therapeutics; as an adjunct in the treatment of acute diseases; as an aid to surgery in the treatment of chronic diseases, and in relation to the prevalent professional psychasthenia.

DISCUSSION

Dr. C. R. Woodson, St. Joseph, Mo.: The physician who possesses the power to entertain, to divert, and to inspire confidence, who can honestly set forth facts and take an individual's mind off of an object of worry, or who can influence him along these lines, is the best psychotherapist.

Dr. A. S. von Mansfelde, Ashland, Neb.: I do not believe that a man can be educated to become a successful psychotherapist. The successful psychotherapist is born, not made.

Dr. R. Willman, St. Joseph, Mo.: Instruction and investigation, if properly given and carried out, will do much toward mitigating and annihilating false mind-healing. Psychotherapy is not new, but physicians have not practiced it to the extent they should have done.

Dr. S. Grover Burnett, Kansas City, Mo.: Before attempting to administer psychotherapy, the physician ought to make a diagnosis. Without a diagnosis, he had better not say or do anything. If a physician has not diagnosed correctly the ailment of a patient, he is just as likely to give pathologic suggestions as he is to give physiologic ones. Babinski says that functional conditions, such as so-called hysteria, are caused by suggestion and relieved by persuasion. While all members of the profession are not ready to accept that statement, the more one studies it the more clearly he sees the basis for it.

Dr. O. Beverly Campbell, St. Joseph, Mo.: I do not believe that 75 per cent. of the people are neurasthenics. I have observed that as I am becoming a better diagnostician from day to day I am able to find pathologic conditions as causes in more cases of neurasthenia than I ever did before. I believe that confirmed neurasthenics need suggestion. They need to be told some things they do not know. If they are in fear of a great calamity, if they believe they are in a serious condition, and the physician can diagnose their cases correctly and say to them, you are not in a serious condition, then psychotherapy is of advantage.

Dr. F. B. Dorsey, Keokuk, Iowa: There is not a practitioner of medicine to-day who is not using psychotherapy to a greater or less degree, but there is a limitation to it. A short time ago I had a case of confirmed neurasthenia. A diagnosis of gall-bladder trouble was made, and the operation disclosed a gall-bladder full of stones. After these were removed the neurasthenia disappeared.

Dr. C. C. Goddard, Leavenworth, Kan.: The general practitioner chases dollars too hard to make accurate diagnoses. I find that when patients with neurasthenia are admitted into private institutions they have not been properly examined by the family physician. If they had been, the patients never would have been sent to such institutions, but treated at home. I think that pathologic conditions are at the bottom of the majority of cases of neurasthenia.

Dr. W. O. Henry, Omaha: The value of this paper lies in the fact that I emphasize the point that all physicians should employ psychotherapy. They should cultivate it as a means of diagnosis, but not to the exclusion of other things. Psychotherapy should be taught in medical schools. I believe that more attention will be given to it in the future than there has been in the past.

The Errors of Mind Healing

Dr. R. Willman, St. Joseph, Mo.: The various healing cults are a danger to the human family. The dangers that follow in the trail of the pernicious practices of the healing cults may be summed up as follows: 1. The mind-healer being a non-believer in the existence of disease, its contagion, infection, etc., does not appreciate the necessity of knowing disease, and because of his unmindfulness of the danger of contaminating others, he leaves all gates open to the spread of disease. 2. The mind-healer has no idea of early diagnosis and proper treatment of disease when it is in its incipiency. Thus the patient is deprived of all opportunity to protect himself from danger and loss of life—things which early diagnosis and proper treatment could easily prevent.

Hemiplegia

Dr. F. E. Coulter, Omaha, read a paper in which he reported a case of hemiplegia with acute onset. He also exhibited the patient. He called attention to the salient points of practical importance in the management of such cases.

DISCUSSION

Dr. R. C. Woodson, St. Joseph, Mo.: The mode of onset of lesions of the central nervous system is of more importance to the physician in making a diagnosis than anything else.

The Non-Surgical Treatment of Tuberculous Arthritis

Dr. H. Winnett Orr, Lincoln, Neb.: Many patients who have old tuberculous sinuses would recover without operation in from six months to a year if carefully treated mechanically. Operative interference, even under the best conditions, prepares the way for mixed infection later.

DISCUSSION

Dr. H. P. Hamilton, Omaha: Methods of extension and fixation are to be commended. If the disease begins in the epiphysis a different method of treatment than extension and fixation will be required. The important thing is to make the diagnosis early while the disease is in the epiphysis only. Usually, when the orthopedic surgeon gets the case, rupture has taken place into the joint, the ligaments and synovial membranes having already become involved in the inflammatory process, and then it is, and then only, the orthopedic surgeon should come in with fixation.

Dr. A. S. von Mansfelde, Ashland, Nebr.: In order to be successful in these cases the surgeon should be a master in the use of plaster of Paris. He should also have a thorough knowledge of the action of the muscles.

The Neglect of the Sacroiliac Joint by the General Practitioner

Dr. Edward Evans, LaCrosse, Wis., emphasized the anatomic importance of the sacroiliac joint, saying that its neglect in the diagnosis of painful and disabling conditions about the back and pelvis leads to improper treatment. He cited illustrative cases, and described the symptoms of strain of this joint, and then discussed the diagnosis and treatment.

DISCUSSION

Dr. A. S. von Mansfelde, Ashland, Nebr.: Men in throwing sacks of grain over their shoulders sometimes produce a partial dislocation of the sacroiliac joint which continues for years and is referred to as chronic nephritis, lumbago, or chronic rheumatism, when in reality nothing more than the dislocation of this joint, complete or partial, is the cause of the trouble.

Dr. H. Winnett Orr, Lincoln: I have seen two cases in which the sacroiliac joint has been strained in the manner described by Dr. Evans.

Dr. S. Grover Burnett: A lawyer sustained an injury in leaping from a street car. The hip-joint seemed normal, but when any force was brought to bear on the pelvis, pain was intense along the sacroiliac joint.

Dr. F. B. Dorsey: A pregnant woman sustained a complete disarticulation at the symphysis and the right sacroiliac synchondrosis. Treatment consisted in placing her in the dorsal position and applying a plaster cast from a little above the waist-line down to and below the knee, immobilizing the knee and the hip. She made a perfect recovery.

Dr. Mary Strong, Omaha: Is the Walcher position, which is frequently used in cases of slight degree of contraction of the pelvic inlet, likely to injure the sacroiliac joint?

Dr. Edward Evans, LaCrosse, Wis.: If a patient be put in the Walcher position, high forceps applied, and the sacroiliac joint strained, one takes care of it afterward, but these slight strains, as a rule, are not cared for by practitioners.

Facts in Ophthalmology of Practical Importance to the General Practitioner

Dr. John Monroe Banister, Omaha: It would be most advantageous to the busy medical practitioner in general practice to possess sufficient ophthalmologic knowledge to recognize the ocular conditions demanding immediate attention, and to acquire the small amount of skill necessary to give palliative treatment of such urgent affections until the services of a specialist can be secured.

DISCUSSION

Dr. A. S. von Mansfelde, Ashland, Nebr.: Eyes have been lost because the general practitioner has not realized the importance of an injury to the eye at the time the case was seen, and more knowledge on his part would have enabled him to deal with such cases successfully.

Dr. B. W. Christie, Omaha.: Medical colleges should not graduate students without giving them an intelligent idea of the use of the ophthalmoscope. They also should be taught how to refract.

Antitetanic Serum in Tetanus

Dr. F. B. Dorsey, Keokuk, Iowa, emphasized the necessity of giving repeated doses of this serum at stated intervals as a prophylactic. Large and repeated doses do not always counteract tetanus when it is once established. He reported five cases.

DISCUSSION

Dr. C. C. Goddard: If there is any virtue in antitetanic serum, it must be used early or not at all. One remedy I am going to try and use it to the limit is apomorphin, as I believe we will get more benefit from it than from chloral.

Dr. R. Willman mentioned a case of tetanus in which he used apomorphin, as well as sulphate of magnesia and sulphate of soda combined, with gratifying results.

Dr. O. Beverly Campbell said that sulphate of magnesia and sulphate of soda are good in their place, but when tetanus is fully developed he would just as soon use Missouri River water. He has never seen a case of true tetanus cured by any method of treatment.

(*To be continued*)

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

DIVISION OF FEES

To the Editor:—Please tell me where I can obtain literature on the subject of division of fees. D. A. Webb, Scranton, Pa.

ANSWER.—A list of literature on this subject was published in this department, Dec. 18, 1909, p. 2117.

WEIGHT OF ASHES AFTER CREMATION OF BODY

To the Editor:—Can you inform me what percentage of the weight should remain after cremation of a human body in one of the up-to-date crematories? Cortlandt D. Field, New York.

ANSWER.—It is learned from the superintendent of a crematory in Chicago that the average weight of ashes from a human body is five pounds. This would be between three and four per cent. of the body weight.

The Public Service

Medical Department of the Army

Changes for the week ended March 19, 1910:

Wadhams, Sanford H., major, ordered on expiration of leave of absence to proceed to Fort Slocum, N. Y., for duty.

Howell, Walter O., 1st lieut., M. R. C., ordered to proceed to Presidio of San Francisco, for duty.

McAndrew, P. H., major, relieved from duty at Fort Mackenzie, Wyo., and ordered to Fort Terry, N. Y., for duty.

Robbins, Chandler P., major, relieved from duty at Fort Terry, N. Y., and ordered to Fort McHenry, Md., for duty.

Shaw, Herbert G., capt., ordered to report on April 25, to Lieut. Col. James G. Glennan, Medical Corps, President of examining board, Army General Hospital, San Francisco, for examination for promotion.

Hall, James F., capt, relieved from duty at Fort Brady, Mich., at expiration of his present leave of absence, and will proceed to Chicago, for duty as attending surgeon in that city.

Humphreys, Harry G., capt., granted 30 days' leave of absence about April 1, 1910.

Mills, Raymond W., 1st lieut., M. R. C., ordered to Fort Ethan Allen, Vt., for duty.

Kerr, James D., 1st lieut., M. R. C., ordered to Fort Howard, Md., for duty.

Winter, Francis A., major, ordered to proceed to New York City, on official business pertaining to the Medical Department.

McMillan, C. W., 1st lieut., M. R. C., leave of absence extended 1 month.

The following named officers of the Medical Corps will report in person on the dates set opposite their respective names to Lieut. Col. Henry P. Birmingham, Medical Corps, president examining board, at the Army Medical Museum Building, Washington, D. C., for examination to determine their fitness for promotion: Captain Paul S. Halloran, June 6, 1910; Captain Peter C. Field, June 6, 1910; 1st Lieut. Henry C. Pillsbury, May 16, 1910; 1st Lieut. Ray W. Bryan, May 16, 1910; 1st Lieut. Bernard S. Gostin, May 16.

Sparrenberger, F. H., 1st lieut., M. R. C., granted leave of absence for 1 month, to take effect April 30, 1910.

The following named officers of the Medical Corps will report in person on the dates set opposite their respective names to Lieut. Col. James D. Glennan, Medical Corps, president of the examining board, at the Army General Hospital, San Francisco, for examination to determine their fintness for promotion: Captain Louis Brechemin, Jr., June 6, 1910; 1st Lieut. Frederick S. Macy, May 16, 1910; 1st Lieut. Guy V. Rukke, May 16, 1910; 1st Lieut. Edgar King, May 16, 1910; 1st Lieut. Howard H. Johnson, May 16, 1910; 1st Lieut. William H. Richardson, May 16, 1910.

Robinson, James L., 1st Lieut., M. R. C., ordered to report to the commanding officer, Fort Worden, Wash., for duty.

DeNancrede, Charles B. G., 1st lieut., M. R. C., ordered to active duty and will repair to this city to deliver lectures to the class at the Army Medical School on Monday, April 11 and 14, 1910; on the completion of this duty will return to his home, Ann Arbor, Mich.

Medical Corps of the Navy

Changes for the week ended March 19, 1910:

Wise, J. C., med. director, detached from duty as president and member of the naval examining and naval medical examining boards, Washington, D. C., and ordered to continue other duties.

Ames, H. E., med. director, ordered to command the Naval Hospital, Puget Sound, Wash.

Anderson, F., med. director, detached from command of the Naval Hospital, Annapolis, Md., and ordered to duty as a member of the Naval examining and naval medical examining boards, Washington, D. C.

Beyer, H. G., med. inspector, detached from the Bureau of Medicine and Surgery, and ordered to continue other duties.

McDonald, P. E., P. A. surgeon, placed on the retired list March 9.

Eaton, W. E., acting asst.-surgeon, ordered to duty at the Naval Hospital, Boston.

Langhorne, C. D., surgeon, detached from the Naval Station, Hawaii, and ordered home to wait orders.

Brownell, C. D. W., surgeon, ordered to the *New Jersey*.

Stuart, A., P. A. surgeon, detached from the *New Jersey*, and ordered to the Naval Medical School, Washington, D. C., for course of instruction.

Hermesch, H. R., asst.-surgeon, detached from the Naval Training Station, San Francisco, and ordered to the *South Dakota*.

Bacon, S., asst.-surgeon, detached from the *South Dakota,* and ordered to the Naval Training Station, San Francisco.

Rossiter, P. S., surgeon, detached from the Naval Station, Tutuila, Samoa, and ordered home to wait orders.

Cottle, C. F., asst.-surgeon, detached from the Naval Hospital, Annapolis, Md., and ordered to duty at the Naval Station, Tutuila, Samoa.

Strite, C. E., P. A. surgeon, detached from the *Franklin*, and ordered to the Naval Hospital, Las Animas, for treatment.

Public Health and Marine-Hospital Service

Changes for the week ended March 16, 1910:

Trask, J. W., asst. surgeon-general, granted 1 month's leave of absence from March 16, 1910.

Carter, H. R., surgeon, granted 1 month's leave of absence from March 11, 1910, on account of sickness.

Lavinder, C. H., P. A. surgeon, directed to proceed to certain places in Germany, for inspection of antitoxin establishments, and on completion of said duty to proceed to Milan and other places in Italy, for investigation of pellagra.

King, W. W., P. A. surgeon, granted 7 days' leave of absence en route to station.

Warren, B. S., P. A. surgeon, detailed to represent the Service at the National Conference on the Education of Dependent, Backward, Truant and Delinquent Children, to be held in St. Louis, May 16-19, 1910.

Stimson, A. M., P. A. surgeon, granted 6 days' leave of absence from March 14, 1910, under paragraph 191, Service Regulations.

Creel, R. H., P. A. surgeon, granted 5 days' leave of absence from March 18, 1910.

Spratt, R. D., P. A. surgeon, granted 15 days' leave of absence en route to station.

Turnipseed, David C., asst.-surgeon, directed to proceed to Baltimore, and report to the Medical Officer in Command for duty and assignment to quarters.

Stiles, C. W., chief, Division of Zoology, Hygienic Laboratory, detailed to represent the Service at the annual conference of state health officers, to be held in Nashville, Tenn., April 6-7, 1910, and the annual meeting of the Tennessee State Medical Association, to be held in Memphis, April 12-14, 1910.

Bean, L. C., acting asst.-surgeon, granted 5 days' leave of absence from March 14, 1910.

DeForest, C. M., acting asst.-surgeon, granted 20 days' leave or absence from April 13, 1910.

Marsh, W. H., acting asst.-surgeon, granted 4 days' leave of absence from March 19, 1910.

Turnipseed, David C., commissioned as Assistant Surgeon in the Public Health and Marine-Hospital Service.

Marriages

James C. Blair, M.D., to Miss Vivian Losse, both of San Jose, Cal., March 8.

Oscar J. Mayer, M.D., Mexico, to Miss Lucy Keller, at San Antonio, Tex., March 5.

Philip August Bill, M.D., to Miss Mary Aileen Ross, both of San Francisco, March 9.

Arthur A. O'Neill, M.D., to Miss Stella L. Montague, both of San Francisco, March 3.

Samuel Schiffman, M.D., to Miss Charlotte Kleinberg, both of New York City, March 6.

James Thomas Nichols, M.D., Muskogee, Okla., to Miss Louise Salisbury, at Baltimore, March 9.

Albert Seward Tenney, M.D., Cambridge, Mass., to Miss Helen L. Fargo Schulte, of South Orange, N. J., January 8.

William John Judy, M.D., Kerens, W. Va., to Miss Jessie Harper Wamsley, of Mill Creek, W. Va., at Cumberland, Md., March 8.

Deaths

Wharton Sinkler, M.D., died at his home in Philadelphia, March 16, aged 64. He was born in Philadelphia, Aug. 7, 1845, received his early education in Gambier, Ohio, and Aiken, S. C., and entered the South Carolina college, but left in his Freshman year, at the outbreak of the Civil War and enlisted in the Second South Carolina Cavalry, C. S. A. At the conclusion of the war he attended lectures in Philadelphia, was graduated in medicine from the University of Pennsylvania in 1868, and continued to practice in Philadelphia until his death. He was a member of the American Medical Association, chairman of the Section on Nervous and Mental Diseases in 1905, and chairman of the executive committee of the section in 1908 and 1909. He was also a member and formerly president of the American Neurological Association, and the Philadelphia Neurological Society; treasurer of the Society of Tropical Medicine; a fellow of the College of Physicians of Philadelphia, the Association of American Physicians, and American Philosophical Society; a member of the National Association for the Study and Care of Epileptics and many other scientific societies. He was trustee of the University of Pennsylvania, manager of the Episcopal Hospital, manager of the University of Pennsylvania Hospital, and attending physician to the Philadelphia Orthopedic Hospital and Infirmary for Nervous Diseases. In 1895 he was one of those responsible for the creation of the Pennsylvania Epileptic Colony Farm, which, on May 2, 1896, was merged with the St. Clement's Hospital for Epileptics, under the title of the Pennsylvania Epileptic Hospital and Colony Farm. Since that time he has served as president of the institution, and as a result of his solicitation a large part of the building fund and endowment was secured. This was the first colony for epileptics to be founded in the state of Pennsylvania and the third in the United States. It is felt by Dr. Sinkler's family and friends that no more fitting memorial could exist for him than this institution which gives noble relief to those unfortunates who cannot be cared for in other institutions or in their homes. He was a frequent contributor to the literature of his specialty.

Frank V. Cantwell, M.D. University of Pennsylvania, 1884; a member of the American Medical Association; chief of the surgical staff of St. Francis Hospital, Trenton, N. J.; a member of the Trenton Board of Health and a common councilor of Trenton; local pension examiner; consulting physician at the State Prison; sometime president of the Mercer County Society, Trenton Medical Association, and Trenton Medical Library Association; at one time physician of Mercer county; one of the leaders in the antituberculosis agitation which resulted in the establishment of the State Sanatorium for Tuberculosis, Glen Gardener; died at his home March 11, from tuberculosis, aged 48.

Mathias Cook, M.D. Starling Medical College, Columbus, 1864; a member of the Medical Society of the State of New York; acting assistant surgeon U. S. Army and afterward surgeon of the Second Ohio Volunteer Cavalry during the Civil War, and volunteer surgeon in the German service during the Franco-German War; a ward physician of Utica for 25 years; one of the original members of the staff of St. Elizabeth's Hospital; for more than ten years local pension examiner, and for most of that time president of the board; in 1889, one of the coroners of Oneida county; a philatelist of national repute; died at his home, March 7, from heart disease, aged 69.

Homer Orman Bates, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1878; of Chicago; a member of the American Medical Association; formerly an instructor in Rush Medical College; professor of obstetrics in the Playfair-Lying-In Hospital; attending physician at Grace Hospital; and a lecturer in the Presbyterian Hospital School for Nurses; surgeon for the Metropolitan Elevated Railroad; formerly president and councilor of the Long Beach Branch of the Los Angeles County Medical Society; died at his home in Sierra Madre, March 10, from cerebral hemorrhage, aged 63.

Nelson Barrere Van Winkle, M.D. Miami Medical College, Cincinnati, 1878; a member of the American Medical Association; for many years a member of the board of pension examiners of Blanchester, Ohio; local surgeon for the Baltimore and Ohio Railroad; and a member of the Baltimore and Ohio Surgeons' Association since its organization; died at his home in Blanchester, March 13, from cerebral hemorrhage, aged 57.

Harrison Tyler Witman, M.D. Jefferson Medical College, 1864; assistant surgeon of the Forty-second Pennsylvania Volunteer Infantry and brevetted major and surgeon for conspicuous bravery on the field; and later surgeon of the One Hundred and Ninety-fifth Pennsylvania Volunteer Infantry; a member of the common council of Reading, Pa.; died at his home, March 6, from pneumonia, aged 72.

William Merrick Gray, M.D. University of Pennsylvania, 1882; pathologist to the Army Medical Museum, and to the Providence Hospital, Washington; an expert in *x*-ray photography; during the Spanish-American War, a member of the staff of the Hospital Ship *Relief;* died March 9 in the laboratory of the Army Medical Museum, from acute dilatation of the heart, aged 51.

Rollin Carolus Olin, M.D. University of Michigan Homeopathic College, Ann Arbor, 1877; professor of practice of medicine in Detroit Homeopathic College; and a member of the medical board of Grace Hospital; a veteran of the Civil War; died at his home, March 8, from cerebral hemorrhage, aged 70.

Charles Auville Board, M.D. University of Virginia, Charlottesville; for more than fifty years a practitioner of Virginia; surgeon in the Confederate Army during the Civil War; for several terms mayor and school trustee of Bedford City; died at his home, February 26, from senile debility, aged 77.

Robert George English, M.D. Northwestern University Medical School, Chicago, 1871; a veteran of the Sabine Indian War; and a pioneer resident of Des Moines, Iowa; for nearly sixty years a practitioner; died at the home of his daughter in Osawatomie, Kan., March 4, from senile debility, aged 92.

John J. Saville, M.D. University of Pennsylvania, 1862; of Chicago; a pioneer practitioner of Sioux City, Iowa; in 1874 made agent of the Rosebud Indian Reservation, S. D.; surgeon of volunteers during the Civil War; and at one time health officer in Omaha; died in that city, March 8, aged 76.

Victor Hugo Sturm, of Traverse City, Mich., a member of the local medical society; president of the Grand Traverse Hospital Association; for many years a practitioner of Cincinnati; died suddenly in Mason City, Iowa, Dec. 8, 1909; from acute dilatation of the heart, aged 76.

Charles Coleman Benson, M.D. University of Maryland, Baltimore, 1883; formerly of Baltimore and Santa Cruz, Cal.; died in his rooms in Philadelphia, March 12, from the effects of poison, believed to have been self-administered with suicidal intent, while despondent, aged 73.

Charles Seaton, M.D. Kentucky School of Medicine, Louisville, 1860; a veteran of the Civil War; from 1882 to 1886, treasurer of Morgan county, Ind.; for several years, manager of sanatoria in Martinsville; died in his office in that city, March 11, from heart disease, aged 74.

John Nevins, M.D. New York University, New York City, 1883; a member and for several terms secretary and treasurer of the Jersey Shore (Pa.) School Board; a member of the Lycoming County Medical Society; died at his home, March 2, from pneumonia, aged 56.

Hallie Thomas Willis, M.D. University Medical College of Kansas City, Mo., 1898; a member of the Missouri State Medical Association; and for many years secretary of the Shelby County Medical Society; died at his home in Shelbina, February 25, from nephritis, aged 46.

Joseph H. Green, M.D. Southern Medical College, Atlanta, Ga., 1881; for several years a member of the faculty of a medical school of Atlanta; and formerly physician of DeKalb county, Ga.; died at his home in Decatur, March 11, from pneumonia, aged 50.

Daniel B. D. Beaver, M.D. University of Pennsylvania, 1871; a member of the American Medical Association; of Reading, Pa.; for several years chief of the surgical staff of St. Joseph's Hospital; died in Okahumpka, Fla., March 6, from tuberculosis, aged 63.

John Frederick Brown, M.D. University of Arkansas, Little Rock, 1891; a member of the Arkansas Medical Society; once president of the Faulkner County Medical Society; died at his home in Conway, March 5, from pneumonia, aged 39.

Daniel Townsend Pope, M.D. Medical College of the State of South Carolina, 1860; surgeon in the Confederate Service during the Civil War; died at his home in Edisto Island, S. C., Dec. 8, 1909, from cerebral hemorrhage, aged 72.

Thomas Milsom, M.D. Harvard Medical School, 1870; for several years surgeon on the Inman Line; a member of the Nova Scotia Medical Association; died at his home in Dartmouth, July 25, 1909, from pneumonia, aged 66.

Isaac Watson Inlow (license, Ind., 1897); a member of the Indiana State Medical Association; for forty years a practitioner of Shelby county; died at his home in Blue Ridge, March 7, from cerebral hemorrhage, aged 70.

Martin Amador, M.D. New York University, New York City, 1878; a member of the Medical Society of the State of New York and Associated Physicians of Long Island; died at his home in Brooklyn, March 15, aged 53.

Samuel Clark Way, M.D. Ohio Eclectic Medical College, Cincinnati, 1866; a veteran of the Civil War; of Johnson City, Tenn.; died in the National Soldiers' Home in that city, February 4, from senile debility, aged 79.

Charles B. Richards, M.D. Western Reserve University, Cleveland, 1852; of Binghampton, N. Y.; surgeon of volunteers during the Civil War; died in St. Petersburg, Fla., March 6, from bronchitis, aged 78.

Bernard Sheridan Kerr, M.D. Victoria College, Coburg, Ont., 1867; a member of the College of Physicians and Surgeons of Ontario, 1869; died at his home in Toronto, March 12, from bronchopneumonia, aged 73.

Thomas Joseph Broderick, M.D. Harvard Medical School, 1882; formerly a member of the Massachusetts Medical Society; died at his home in Charlestown, Boston, March 5, from cerebral hemorrhage.

Henry B. Day, M.D. University of Oregon, Portland, 1905; formerly of Dayton, Wash.; died at his home in Tacoma, Wash., Dec. 6, 1909, from the effects of an overdose of chloroform, aged 25.

Daniel Edmond Barry, M.D. College of Physicians and Surgeons, New York City, 1871; a member of the American Medical Association; died at his home in New York City, March 12, aged 60.

Ulysses S. Ingram, M.D. Hospital College of Medicine, Louisville, 1896; of Pineville, Ky.; died in a sanitarium in Louisville, March 11, from typhoid fever, following pneumonia, aged 35.

William Frederick Knapp, M.D. University of Michigan, Ann Arbor, 1878; of Monroe, Mich.; died in St. Joseph's Retreat, Dearborn, Mich., March 10, from cerebral hemorrhage, aged 60.

Benjamin H. Leslie, M.D. University of Pennsylvania, 1868; a member of the Kansas Medical Society; died at his home in Lawrence, Kan., March 15, from chronic nephritis, aged 66.

Alfred Augustus Stocker, M.D. Harvard Medical School, Boston, 1853; a surgeon of volunteers during the Civil War; died at his home in Cambridge, Mass., March 10, aged 90.

Frank W. Nelson, M.D. Jefferson Medical College, 1880; a member of the Medical Society of Virginia; died at his home in Forest Depot, March 8, from heart disease, aged 54.

Charles W. Hayes, M.D. Cleveland University of Medicine and Surgery, 1871; of Omaha; died in a hospital in Los Angeles, Cal., March 7, from heart disease, aged 63.

Henry H. Bartlett, M.D. Cleveland Homeopathic Medical College, 1869; formerly of Ashtabula, Ohio, and Los Alamitos, Cal.; died suddenly in Pasadena, May 3, 1909.

Samuel Holman, **M.D.** Bellevue Medical College, 1866; a member of the Medical Society of the State of New York; died at his home in Hilton, March 4, aged 68.

Robert L. Thompson, M.D. College of Physicians and Surgeons, Baltimore, 1891; died at his home in Traphill, N. C., February 20, from pneumonia, aged 50.

William N. Cronin, M.D. Starling Medical College, Columbus, Ohio, 1887; died at his home in Hartford City, Ind., March 9, from heart disease, aged 47.

Jesse Snowden, M.D. Central College of Physicians and Surgeons, Indianapolis, 1883; died at his home in Indianapolis, March 8, from heart disease, aged 75.

Oliver Richardson King, M.D. College of Physicians and Surgeons, New York City, 1852; died at his home in Plainfield, N. J., March 13, from heart disease.

William Hawtry Bredin, M.D. Trinity Medical College, Toronto, 1869; formerly of Picton, Ont.; died at his home in Toronto, Nov. 11, 1909, aged 81.

William Penn Dicks, M.D. Washington University, Baltimore, 1875; died at his home in Walkertown, N. C., February 18, from neurasthenia, aged 71.

D. W. Cooper, M.D. Physio-Medical College, Cincinnati, 1879; died at the home of his daughter in Oakdale, Tenn., March 7, from paralysis, aged 60.

Edward Louis Menager, M.D. University of Rennes, France, 1869; died at his home in Spokane, Wash., March 9, from tuberculosis, aged 57.

John S. Marshall, M.D. Medical College of Virginia, Richmond, 1888; died recently at his home in Smithfield, Va., and was buried March 7.

William Diehl, M.D. New York Homeopathic Medical College, New York City, 1891; died at his home in Brooklyn, March 7, aged 47.

Pleasant W. McKeel, M.D. Vanderbilt University, Nashville, 1878; died at his home in Mayfield, Ky., March 9, from pneumonia, aged 57.

Nathan J. Langston, M.D. Southern Medical College, Atlanta, Ga., 1894; died at his home in McDonough, Ga., March 6, aged 65.

W. T. Stone, M.D. Memphis (Tenn.) Medical College, 1858; died at his home in Milan, Tenn., February 28, from influenza, aged 81.

Mikhail Farag, M.D. College of Physicians and Surgeons, Baltimore, 1907; died recently at his home in Tanta, Egypt.

Charles S. Kerr, M.D. University of Maryland, Baltimore, 1868; died at his home in Kerr, N. C., March 6, aged 65.

Albert G. DuPuy, M.D. Tulane University, 1878; died at his home in Tennessee Colony, Texas, March 11.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Arizona: Phoenix, April 4-5. Sec., Dr. Ancil Martin.
California: San Francisco, April 5. Sec., Dr. Charles L. Tisdale, 929 Butler Building.
Colorado: Denver, April 5. Sec., Dr. S. D. VanMeter, 1723 Tremont Place.
Florida: Jacksonville, April 4-5. Sec., Dr. J. D. Fernandez.
Idaho: Boise, April 5. Sec., Dr. O. J. Allen, Bellevue.
Illinois: Chicago, April 14-16. Sec., Dr. J. A. Egan, Springfield.
Minnesota: State University, Minneapolis, April 5. Sec., Dr. W. S. Fullerton, 214 American Nat'l Bank Bldg., St. Paul.
Montana: The Capitol, Helena, April 5. Sec., Dr. W. C. Riddell.
New Mexico: Santa Fe, April 11-12. Sec., Dr. J. A. Massie.
North Dakota: Grand Forks, April 1-4. Sec., Dr. H. M. Wheeler.
Oklahoma: Ione Hotel, Guthrie, April 12. Sec., Dr. Frank P. Davis, Enid.
Rhode Island: State House, Providence, April 7-8. Sec., Dr. Gardner T. Swarts, Room 315, State House.
West Virginia: Wheeling, April 12-14. Sec., Dr. H. A. Barbee, Point Pleasant.

Washington July Report

Dr. J. Clinton McFadden, secretary of the Board of Medical Examiners of the State of Washington, reports the written examination held at Seattle, July 6-8, 1909. The number of subjects examined in was 11; total number of questions asked, 110; percentage required to pass, 60 in each branch. The total number of candidates examined was 296, of whom 262 passed, including 186 osteopaths, and 34 failed, including 3 osteopaths. The following colleges were represented:

College	Year Grad.	Total No. Examined.
PASSED		
University of California ....(1896) (1907)	(1908)	3

Rhode Island January Report

Through an error, the wrong percentage figures were given in The Journal of Feb. 26, 1910, for the candidates who passed the examination held by the Rhode Island State Board of Health, Jan. 7-8, 1910. The correct figures are as follows:

College	Year Grad.	Per Cent.
PASSED		
College of Physicians and Surgeons, Baltimore....	(1903)	86.6
Harvard Medical School	(1907)	83.6
Dartmouth Medical School	(1908)	80
University of Vermont...........................	(1909)	80
FAILED		
Baltimore Medical School........................	(1907)	71.4
Atlantic Medical College, Baltimore.............	(1909)	61.9
Boston University	(1899)	63.4
Laval University, Canada...........(1904) 61.4;	(1909)	67.9

Book Notices

La Cure Radicale de la Hernie Inguinale: Leçons professees à l'Hôtel-Dieu. Par le Docteur Lucas-Championnière, Chirurgien Honoraire de L'Hôtel-Dieu, Membre de l'Académie de Médecine. Paper. Pp. 192, with 53 illustrations. Price, 3.50 francs. Paris: G. Steinheil, Editeur, 2 Rue Casimir-Delavigne, 1909.

This volume represents the views of the author, and describes his method, but there is too much detail and much useless repetition. Twenty pages are devoted alone to a description of ligation of the omentum, the method being in short the application of a series of interlocking ligatures. There are three fundamental procedures involved in the cure of all hernias, namely: (1) Total ablation of the hernial sac; (2) proper repair of the abdominal wall; and (3) extirpation of the omentum. The author properly lays stress on the high ligation of the sac, and scrupulously avoids leaving any suggestion of an infundibulum behind, and there is no question that this simple maneuver makes for permanency of cure. Most hernias are admitted to be of congenital origin. Repair of the wall implies the employment of the imbrication principle, of which more later.

On the subject of ligation of the omentum the statement is made that no operation merits the name of radical operation which omits removal of the omentum. It is advised that one should remove all of the omentum, everything within reach, the entire organ if possible. Ligation *en masse* is rightly condemned. Catgut is the suture and ligature material employed. One fairly large size is used for all purposes and is prepared by immersion for six months in a 5 per cent. solution of carbolic acid in oil. Great caution is urged to secure absolute hemostasis, to which all surgeons would readily subscribe. Priority and superiority over Bassini is claimed.

The steps of the repair are described minutely, the essential feature being the imbrication of the external oblique fascia. The author differs radically from others practicing overlapping methods in that he applies mattress sutures in such a manner as to pull the lower flap of external oblique fascia under the upper. The upper flap is then laid down and sutured, the cord being placed between the two layers. Thus it appears that the internal oblique and transversalis muscles are not sutured to Poupart's ligament, an omission which makes the method inferior to the Andrews modification. In women the round ligament is removed.

Before suturing the skin the author irrigates the wound with a 5 per cent. solution of carbolic acid, and drains. Among 1,134 operations reported there were 4 deaths, one of them being from chloroform, the anesthetic which is used.

The author has never seen a case of early recurrence; however, in 28 years he estimates the recurrences at 4.1 per cent. He does not advise operation before the age of 5 or 7. Obesity he considers the strongest contraindication to operation. The patients are kept in bed three weeks.

The illustrations are good and clear, and the little volume makes pleasant reading, though it would gain by being boiled down and better systematized. The author's method never would find favor among American surgeons, agreeing as they do as to the excellence of the principle of imbrication.

Selected Papers on Hysteria and Other Psychoneuroses. By Prof. Sigmund Freud, Vienna. Authorized Translation by A. A. Brill, Ph.D., M.D., Chief of Nervous Dispensary, Beth Israel Hospital. Paper. Pp. 200. New York: The Journal of Nervous and Mental Disease Publishing Co., 1909.

The work of Breuer, Freud, Jung, Ferenczi and their pupils has thrown a flood of light on the nature and treatment of hysteria and similar psychoneuroses. Indeed, even the pure psychoses are being attacked by the searching psycho-analytic methods of these untiring investigators.

Following the lines of the newer experimental psychology, and even adding to this psychology by his own investigations, Freud has given us a new and definite conception of hysteria, that *bête noire* of the general practitioner. It is decidedly reassuring to learn that hysterical symptoms are the symbolic expression of the realization of a repressed wish, which expression serves as a gratification for the patient, and that "the hysteric suffers mostly *from reminiscences.*" In the two cases reported, illustrating the method of examination and physical analyses and the happy results of treatment along lines of well-defined and rational psychotherapy, the author says, "the individual hysterical symptoms immediately disappeared without returning if we succeeded in thoroughly awakening the memories of the causal process with its accompanying affect, and if the patient circumstantially discussed the process, giving free play to the affect" (p. 4).

However convincing may be the many cases thus subjected to a rigid psycho-analysis and rational psychotherapy by Freud and his followers, we fear that their teachings will never become popular in the profession, for "the process is toilsome and wearisome for the physician and it presupposes a profound interest for psychologic incidents as well as a personal sympathy for the patient" (p. 84). Nevertheless, no one who pretends to practice scientific medicine can afford to neglect a careful study of the work of this group of earnest and practical psychologists.

Freud's views on what he calls the "anxiety neuroses" and on the prominent rôle of sexuality in the etiology of the neuroses are well elaborated in three of the essays. They have not met the same favor, however, as have his views on the psychic nature and treatment of hysteria.

Two of the essays, those on the general subject of psychotherapy, are particularly timely and deserving of special perusal because of the rational and scientific conservatism with which this much-maligned subject is handled. The difficulty with which the abstract reasonings of scientific psychology are followed is doubled in a language to which one is not born. Freud himself, moreover, is hard to read by reason of his close logic, somewhat original terminology and refined psychology. It is therefore a matter for self-congratulation on the part of the English-reading student to be given this *excellent and clear translation* by Dr. Bill, who is himself an active neurologist and knows the practical needs of the profession.

Pulmonary Tuberculosis and Sanatorium Treatment. By C. Muthu, M.D., M.R.C.S., L.R.C.P. Associate of King's College, London. Cloth. Pp. 201, with illustrations. Price, 3 shillings 6 pence net. London: Baillière, Tindall and Cox, 8 Henrietta Street, Covent Garden, London, 1910.

The author has had ten years' experience in open-air sanatorium treatment of the disease and writes with convictions and reason. The first chapters are devoted to the etiology of tuberculosis, with a brief account of symptoms and prognosis. The author elaborately considers the relatively great importance of predisposing conditions, insisting that the bacillus is not the whole or sole cause of the disease. Whether, as he believes, man became afflicted with tuberculosis only after he became a house-dweller cannot be proved, and whether the bacillus was first able to live outside animal bodies and gradually acquired a parasitic habit is also incapable of proof. But these views appeal to the imagination if they do not convince the reason.

The author's discussion of the early diagnosis of pulmonary tuberculosis is good, but too brief. Tuberculin tests he deprecates as often dangerous. The practical application of the opsonic index as a test he thinks is very limited. The Calmette reaction he thinks is uncertain and unreliable.

It is unfortunate that he did not consider the subject of prognosis more fully and practically. He says that it will depend "first on the strength of vital resistance" (but does not tell us how to estimate this), and second, on the way that resistance is used.

The second part of the book, on open-air sanatorium treatment, is good and deserves praise. The author recognizes the need of rest when a patient's temperature is 99 F. or over, but he also appreciates the need of exercise for every patient who can take it. The kinds which he commends are walking, breathing, singing, reading, manual training and tramping. These exercises and the indications and contraindications for them he describes fully. By tramping he means excursions during which one walks, camps and leads a simple outdoor life. It is of course adapted only to those who have nearly or quite made an apparent recovery. The utility of inhalation of formalin or mixtures of it, chloroform and aromatics is discussed at some length and advocated. The usefulness of static electricity is also considered and urged, not as a specific but an aid. Part 3 is an interesting consideration of the social and economic factors of tuberculosis, remedial and preventive measures.

The Prevention and Treatment of Abortion. By Frederick J. Taussig, A.B., M.D., Lecturer in Gynecology, Medical Department, Washington University. Cloth. Pp. 179, with 59 illustrations. Price, $2. St. Louis: C. V. Mosby Co., 1910.

Taussig found in six hundred hospital patients that the ratio of abortion to confinement was 1 to 2.3. This frequency is greater than that found by most writers who generally state the frequency is as 1 to 5. The anatomy and pathology is clearly presented and illustrated by numerous cuts, many of them original. Under etiology a classification of the causes is given that is clear and satisfactory. Under exciting causes and especially death of (or injury to) the fetus by placental interference with nutrition should be included placenta prævia. In the chapter on symptoms and clinical course it is stated that fever is frequently present and due to the decomposition of decidua or placenta. The mistaken impression is left that this is something else than sapremia. The very important subject of diagnosis and differential diagnosis as also the short discussion on prognosis are excellently presented.

In Part 2, "Prevention of Abortion" prophylaxis is considered under the heads of prophylaxis before conception, during pregnancy, in threatened abortion and prevention of criminal abortion. The importance of the Wassermann reaction to determine syphilis in cases of habitual abortion is pointed out. In speaking on legislation as a means of preventing criminal abortion the author surprises us a little by suggesting that the Federal Government should control the matter of abortion and intimating that every abortion, no matter what the cause, should be officially reported. The difference between the registration of deaths where burial certificates can be required and the registration of abortion where the egg can be easily destroyed is so great that the suggestion impairs one's confidence in the author's practical judgment with this field of medicolegal practice.

The treatment of abortion is characterized by a wise but temperate conservatism. The operative technic including curettage is described fully. Curettage is rarely indicated in cases of sepsis. The chapter on perforation is very valuable. Chapters on missed abortion, mole pregnancy, threatened abortion and ergot and its preparations close the book.

The work can be highly commended as a concise, practical and timely presentation of an important and frequently neglected subject.

New and Nonofficial Remedies, 1910. *Containing Descriptions of the Articles which have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association, prior to Jan. 1, 1910.* Paper, 25 cents; Cloth, 50 cents. Pp. 256.

To the conscientious physician who wishes to go outside of the Pharmacopeia and the National Formulary preparations in his prescribing, this annual will prove valuable. It gives him within a brief space information as to the new non-official and especially proprietary drugs about which it would be almost impossible for him to obtain information, except from the manufacturers themselves. It is the only source from which the physician can obtain reliable information regarding them.

The 1910 edition has been revised and contains descriptions of such new drugs as seem worthy and which have been accepted by the Council on Pharmacy and Chemistry of the A. M. A., prior to Jan. 1, 1910. The most notable addition is that of serums and vaccines, and the importance this method of treatment is assuming makes a collation of information concerning them of the utmost value to the physician. Notes of caution properly have been added with reference to the antipyretics and intestinal antiseptics, and with reference also to the assertions of manufacturers that certain drugs are non-poisonous or non-irritating. The Annual follows the plan of the former one and should prove indispensable to the physician and the pharmacist who need reliable information on non-official and especially on proprietary drugs.

Nervous and Mental Diseases. Edited by Hugh T. Patrick.
M.D., Professor of Neurology in the Chicago Polyclinic and Charles
L. Mix, A.M., Professor of Physical Diagnosis in
University Medical School. Vol. X of The
Series under the General Editorial Cha
M.D., Professor of Laryngology and Rhin
Medical School. Cloth. Pp. 248, with
Series 1909. Chicago: The Year-Book Publishers.

In this volume, covering the work of the year in nervous and mental diseases, several things stand out rather prominently. One is a changing view in regard to hysteria, there being a distinct movement in the study of this disease to classify manifestations, to give each a more significant separate designation, to find a distinct pathology for it, and to ascribe a very large proportion of symptoms, such as sensitivosensorial hemianesthesia, contraction of the visual field, monocular polyopia, dyschromatopsia, loss of pharyngeal reflex, hysterogenetic zones, etc., to unconscious suggestion, usually of medical origin. It may well be that with further study of the neuroses the term "hysteria" will become obsolete. Another suggestion that would seem to have a reasonable basis is that chorea is a symptom and not a separate disease and that the effort to attribute it to some specific infectious cause is not justified. Incoordinated muscular movements in the adult and the old are attributed to arteriosclerosis, faulty nutrition, toxemia, etc., causing lost action of the motor control cells. To many causes just as general may be attributed this incoordination in children. Almost unanimous testimony is given as to the distinct value of the Flexner-Jobling serum in meningitis. The serodiagnosis of syphilis has placed tabes and general paralysis of the insane more certainly among the so-called parasyphilitic diseases. Mental diseases are given very little space and there is little editorial comment throughout the book. An index of subjects and authors completes the book.

Contributions to the Study of Rectal Disease. By F. Victor Milward, B.A., M.B., B.C., F.R.C.S., Assistant Surgeon to the General Hospital, Birmingham. Cloth. Pp. 92, with illustrations. Price, 2 shillings. Birmingham, England: Cornish Brothers, 1909.

This is a very imposing title for a little duodecimo brochure of some ninety pages. Eight chapters are devoted respectively to "Palliative Treatment of Hemorrhoids," "Signficance and Recognition of Blood Passed Per Anum," "Stricture of the Rectum in its Relation to Disease," "Two Cases of Carcinoma Extirpated by the Vagino-Perineal Route," "Congenital Piles," "Obstipation and Its Relation to Constipation," "Pain of Anal Origin and Its Alleviation," and "The Sigmoidoscope as a Means of Diagnosis in Rectal Disease."

There is nothing especially novel in the treatment of any of these topics. For example, under the structure of the rectum, mention is made of cases of constipation without bowel action "for months." The circumference may be "immensely increased." The majority of these cases of constipation of months' duration are examples of Hirchsprung's disease in which the rectum is not involved, the dilatation stopping short at the commencement of the latter. We fear our late distinguished visitor, M. Thomas Jonnesco, will hardly recognize himself when reported as Jonowsky. Proctology must be at a rather low ebb in Great Britain when it is necessary to recommend the use of the sigmoidoscope. Altogether, there is no danger that this work will supplant those to which we are accustomed in this country.

The Medical Complications, Accidents and Sequels of Typhoid Fever and the Other Exanthemata. By Hobart Amory Hare, M.D., B.Sc., Professor of Therapeutics in the Jefferson Medical College of Philadelphia, and E. J. G. Beardsley, M.D., L.R.C.P., Assistant Physician to the Out-Patient Department of the Jefferson Medical College Hospital. With a Special Chapter on the Mental Disturbances Following Typhoid Fever. By F. X. Dercum, M.D., Professor of Mental and Nervous Diseases in the Jefferson Medical College. Cloth. Pp. 391, with [illegible] illustrations. Price, $3.25 net. *Philadelphia*: Lea & Febiger.

The present edition of this work is a full revision of the former edition of ten years ago, with a summary of the literature since that time, and the addition of five new chapters in the complications and sequelæ of variola, scarlet fever, measles, varicella and rubella. Nearly 300 pages are devoted to typhoid alone, and deal only with atypical, or unusual manifestations, and their differential diagnosis. The review of the literature is exhaustive and up to date, and full references, often in great profusion, are given at the bottom of each page. A valuable feature is the abundance of statistical information given throughout the volume. The treatment is left untouched. The reader will perhaps find it a little difficult to see just why the complications and sequelæ, alone, of the exanthemata should be included in a volume three-fourths of which is devoted to typhoid, and will perhaps feel a little regret that the whole volume was not devoted to typhoid alone, including treatment. The book is, notwithstanding, a valuable monograph on the subject with which it deals.

Practical Hydrotherapy. By Curran Pope, M.D., Professor of Physio-Therapy, University of Louisville Medical Department. Cloth. Pp 646, with Illustrations. Price, $6. Cincinnati Medical Book Co., 1909.

This is a sane book on the subject, one free from the fads and freakishness so frequently found in works dealing with special methods of therapy. The author makes it plain at the outset that while thoroughly appreciating the value and advantages of hydrotherapy, he "fully realizes that it is not a cure-all," and he has written the book "with a full comprehension of the real value and the limitations of this agent." To this general standard the author in a great degree adheres. Not but that he is more enthusiastic and optimistic than most of the readers of his book will be over the possibilities of hydriatics; this is to be expected and—for the work to be of value—desired. Strictly speaking, the book deals not with hydrotherapy alone, but also with what the author terms the "associated procedures" of phototherapy and thermotherapy. Moreover, in the therapeutic portion of the book the use of water is in many cases recommended as entirely secondary to the medicinal, dietetic or hygienic treatment. The book is well prepared mechanically, and is rather freely illustrated. From a literary standpoint one criticism must be made: the author has a disconcerting habit of changing from the first to the third person even in the same paragraph.

Clinical Studies for Nurses. By Charlotte A. Aikens, formerly superintendent of Columbia Hospital, Pittsburg. Cloth. Pp. 510, with illustrations. Price, $2 net. Philadelphia: W. B. Saunders Co., 1909.

This is a companion volume to "Primary Studies for Nurses," which we reviewed Aug. 7, 1909. The name, "Clinical Studies for Nurses," is rather misleading, as it suggests practice of medicine; the book, however, is devoted chiefly to definition and description of the various diseases, with enumeration of the symptoms, complications and sequelæ which it is essential that a nurse should be able to recógnize. The author acknowledges that the book is a compilation, and that she has tried to take average statements, as many standard text-books differ in such things, for example, as the length of incubation periods. Considerable space is given to obstetric nursing. Miss Aikens believes that all nurses should be taught how to give massage, and Section IV is given up to "Physical Therapeutics, Massage, and Nursing in Nervous and Mental Diseases." There are six hundred questions for self-examination and review, the subjects of some of which are hardly within the province of a nurse. In appendices are hospital and invalid dietaries, diet-lists, notes on infant-feeding, methods of preparation of surgical materials, and formulas of solutions in use in most hospitals.

Skin and Venereal Diseases: Miscellaneous Topics. Edited by W. L. Baum, M.D., and Harold N. Moyer, M.D. Vol. IX of the Practical Medicine Series. Under the General Editorial Charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Postgraduate Medical School. Cloth. Pp. 240, with illustrations. Price, $1.25. Series 1909. Chicago: The Year-Book Publishers.

The literature of a great number of subjects is reviewed, but in a very interesting manner. In the department of skin and venereal diseases pellagra, now much to the fore, is given considerable space and our knowledge concerning it is very well summarized. Leprosy and what is called leprophobia, on account of a recent case in Washington and New York, are given considerable attention. The vaccine treatment of gonorrhea, syphilis and its serodiagnosis, and a group of diseases called syphiloid whose nosology is now looming up in the literature are treated interestingly. In the miscellaneous department are included the subjects of heredity, the autoprotective mechanism of the body according to the theory of Sajous (a most interesting one), alcoholism, longevity, necessity of autopsies, medicoethical and medicolegal questions, the birth-rate, matters concerning the profession at home and abroad, and many others, all going to make up an interesting summary of the year's work in the special department of skin and genito-urinary diseases and in the general field of medical literature.

Preventable Diseases. By Woods Hutchinson, A.M., M.D., Author of "Studies in Human and Comparative Pathology," etc. Cloth. Pp. 442. Price, $1.50. Boston: Houghton Mifflin Co., 1909.

Many of the chapters of this book have appeared as separate articles in lay magazines from time to time. Some of the subjects are: "Colds and How to Catch Them;" "Appendicitis, Nature's Remnant Sale;" "Diphtheria, The Modern Moloch: Offering up a Guinea-Pig for the Life of a Child." These indicate the attractive popular style of the author, which is clearly a considerable factor in making the book of service in the education of the public on medical and sanitary topics. The graphic portrayals of the vast benefits which the public is daily receiving through facts learned by means of animal experimentation should prove of great value in giving the public the truth on this subject.

It would be justifiable to criticize Dr. Hutchinson on the ground that he is too severe in his censure of some popular ideas, and that he does not leave room for the exceptions that modify all general rules. It would be ungracious, however, to dwell on the trivial faults of a work which, all must agree, has so much to commend it; it is supplying the public with much needed information about disease and health.

Diseases of the Stomach. By S. H. Habershon, M.A., M.D., F.R.C.P. Pp. 565, with 8 colored and 11 black-and-white plates. Price, $2.50. Chicago: Chicago Medical Book Co., 1909.

Dr. Habershon has undertaken to produce a treatise of moderate size on diseases of the stomach, instead of attempting to bring his father's work on diseases of the abdomen up to date, as he has often been requested to do. The result is a satisfactory volume, which gives the essentials of the subject. Special attention is given to the symptomatology of stomach diseases, which are treated, each symptom separately, in two chapters disconnected from the description of the diseases in which they occur, and to the relation of the stomach to other organs. The laboratory methods of diagnosis are given with sufficient fulness for practical purposes.

Vital Economy. By John H. Clarke, M.D. Cloth. Pp. 119. Price, 50 cents net. New York: A. Wessels, Newold Publishing Co., 1909.

This small book is full of meat. It is a protest against the careless taking of general principles—even though those principles be excellent in most cases—as rules to be followed by every patient. In other words, it is a plea for exceptions as careful judgment indicates to the individual. Among the subjects treated in this iconoclastic way are exercise, bathing, outdoor sleeping, etc. The book is primarily written, however, to aid the near-strong and the near-well to remove some small defect in habit or environment which prevents the realization of the highest physical possibilities. The use of coffee, tea and other stimulants are set forth as full of harm.

Doctor Rast. By James Oppenheim, Author of "Monday Morning and Other Poems." Cloth. Pp. 321. Price, $1.50. New York: Sturgis & Walton Co., 1909.

A series of stories, separate but with the same principal characters. The scenes are laid among the Jews of New York City, and the emotions and privations of these people are portrayed in vivid colors. The doctor—would that we all were of as noble stuff as he—shares their joys and sorrows and practices medicine more for the good that he does than for the money he gets out of it. The book is worth reading for pure pleasure, and considerable inspiration and sympathy are likely to be received in the process.

Recent Advances in Physical and Inorganic Chemistry. By A. W. Stewart, D.Sc., Lecturer on Organic Chemistry in the University of Belfast. Cloth. Pp. 250. Price, $2.50. New York: Longmans, Green & Co., 1909.

This is a series of essays or short theses on selected chapters of physical chemistry, which contain the latest results of researches in the special fields taken up. The work covers both organic and inorganic physical chemical research. It is, in short, a compilation of the most advanced work in the several divisions of physical chemistry with the experimental details and calcúlations omitted, presenting only the ultimate findings, and making a survey which will instruct without tiring.

Milk and its Relation to the Public Health. By Various Authors. Hygienic Laboratory Bulletin No. 56. (Revised and enlarged edition of Bulletin No. 41.) Paper. Pp. 829, with 66 illustrations. Washington: Government Printing Office, 1909.

This volume is the second and enlarged edition of Bulletin No. 41 of the Hygienic Laboratory. The first edition having been exhausted the work has been revised, some of the sections added and the new volume bids fair to be of greater value to the hygienist.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

County Society Acts on Ophthalmia Neonatorum

The Tippecanoe County (Ind.) Medical Society has sent out a circular letter to each county society in the state, calling attention to the fact that 35 per cent. of the blindness in Indiana is due to ophthalmia neonatorum and asking for the cooperation of the profession by county and district society action in hopes of abolishing the disease in the state. The special committee on this subject, appointed by the Tippecanoe County Society, recommends that the widest publicity be given the Credé method and that all societies cooperate to secure at the next legislature the passage of a law that will aid in stamping out this preventable disease. It is also recommended that each county society appoint a committee on ophthalmia neonatorum to take up the work in the county and that reports be sent in not later than May 15, in order that the Committee on Ophthalmia Neonatorum of the American Medical Association may be able to report at the St. Louis meeting. Such action is highly commendable. This propaganda should be taken up by each state society.

Contract Practice in Norway

A bill on the subject of compulsory insurance of wage earners is now before the legislature of Norway. Recent issues of the *Medicinisk Revue* contain several articles on the attitude to be taken by the profession in the matter. Loennecker denounces the evils of contract practice both from the standpoint of the physician and of the sick policy-holder, urging the advantages of payment for individual services and the free choice of a physician. Silvertsen extols the benefits that would follow the appointment of a district physician, on a living salary, for each 2,000 inhabitants. Thus for a town of 60,000 he would have 30 physicians who by their official position would be able more effectually to take the lead in large movements for hygiene, prevention of tuberculosis, etc., than is possible for physicians at present in their private capacity.

Legislative Notes

NATIONAL LEGISLATION

A bill has been introduced in the Senate (S. 6877) to amend the act incorporating the American National Red Cross, which became a law in 1905, by adding a section forbidding any person corporation or association other than the American National Red Cross and its employees and agents to use the emblem of the Greek red cross on white ground. Owners of trade-marks registered in the United States Patent Office prior to Jan. 5, 1905, are exempt.

WASHINGTON

The Washington legislature has adjourned. The Committee on Medical Legislation and Public Policy of the state medical association, had introduced into the senate of the state of Washington a bill requiring attending physicians or surgeons to testify as to the facts observed and excluding the testimony of physicians or surgeons on "opinions formed." Expert testimony is to be given by physicians or surgeons appointed by the court entirely independent of either side in the case. The bill aims to secure true expert testimony, without bias. This bill passed the senate and, it is stated, would have passed the house had it been introduced in time.

H. B. 114 was introduced at the request of the state medical association committee and passed by the legislature. This is a bill regulating the practice of medicine and providing for a single board composed of five members from the regular profession, two homeopaths and two osteopaths. All persons who treat the sick or afflicted are required to appear before this board for examination. Three forms of certificates are authorized: one allowing the holder to practice medicine and surgery; one allowing the holder to practice osteopathy, and one allowing the holder to practice any other system or mode of treating the sick not referred to in the section. Registration of certificates with the county clerk is required.

NEW YORK

Among bills that have passed the assembly is one establishing at Yorktown, Westchester county, the Mohansic State Hospital for the Insane and providing for a board of managers to be appointed by the governor within ten days after the bill became a law. This hospital is intended to relieve the congestion existing in the Manhattan and King's Park state hospitals. A bill has been introduced into the assembly to require that greater precautions be taken by sellers of cocain and other drugs of the kind. A bill has been introduced to require the Board of Education to supply pupils with eyeglasses after the need has been determined. The board is authorized to raise $15,000 a year for the purpose.

On February 23, Mrs. Diana Belais, head of the New York Antivivisection Society, Stephen Coleridge and the counsel for the society appeared at a joint hearing in the assembly chamber on the Brough-Murray antivivisection bill. Dr. Simon Flexner, Dr. James Ewing and Prof. Frederick S. Lee argued against the measure. The bill puts the practice of vivisection under the supervision of the State Board of Regents, provides for the inspection of laboratories where vivisection is conducted, by inspectors appointed by the regents at the suggestion of the humane societies, and for the licensing of operators.

OHIO

A number of bills of interest to the medical profession have been introduced into the Ohio legislature, as follows:

S. B. 24, to provide for the disinfection of the house and contents in which a person has had pulmonary tuberculosis; S. B. 44, to provide for special elementary schools for children afflicted with tuberculosis; S. B. 51, the usual optometry bill; S. B. 61, to authorize the Ohio State Board of Health to establish a bureau for the prevention of infectious and contagious diseases; S. B. 121, to provide that a certain proportion of the taxes shall be used for the maintenance of district tuberculosis hospitals; H. B. 111, to legalize the sterilization of confirmed criminals, idiots, imbeciles, epileptics, etc.; H. B. 116, to regulate the conduct of maternity houses and lying-in hospitals; H. B. 119, to regulate the care of dependent and neglected children; H. B. 173, to provide physical education in city and village school districts; H. B. 204, to regulate the sale of cocain, heroin and eucain; H. B. 205, to amend the statute now in force giving jurisdiction to justices of the peace, police judges and mayors by adding a section authorizing them to hear cases regarding the sale of cocain, heroin and eucain; H. B. 244, to add chicken-pox, measles and whooping-cough to the list of reportable diseases; H. B. 385, to regulate the itinerant vending of medicines, nostrums and appliances for the treatment of disease; H. B. 408, amending the statutes providing for the care of school children by providing that each child shall be annually examined for sight, hearing and obstructions to breathing, the examinations to be held under the control of the Ohio State Board of Health.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
Bowling Green, Kentucky

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Eighth Month—Second Weekly Meeting

Pharmacologic and Therapeutic Actions of Drugs (Continued)

II. Drugs Acting on the Blood: A. Drugs acting on the plasma. Alkalizers of the plasma, purgatives, diaphoretics and diuretics. B. Drugs acting on the red corpuscles. Direct and indirect hematinics. Drugs altering composition of hemoglobin, CO, coal-tar derivatives, etc. C. Drugs acting on white corpuscles.

III. Drugs Acting on the Cardiac Mechanism: A. Drugs acting on the heart directly. Drugs which (a) increase force of contraction, (b) decrease force of contraction, (c) increase rate of heart beat, (d) decrease rate, (e) increase both force and rate, (f) decrease both force and rate. B. Drugs acting on vagus center. C. Drugs acting on accelerating center.

IV. Drugs Acting on the Blood-Vessels: A. Drugs acting locally on vessels. 1. Dilators, irritants, rubefacients, vesicants, pustulants, escharotics. Counter-irritation. 2. Constrictors (a) contract muscular coat. (b) coagulate albuminous fluids around vessels. B. Drugs acting on vasomotor centers. 1. Vaso-dilators. 2. Vaso-constrictors. Astringents, styptics.

V. Drugs Acting on the Skin: A. Diaphoretics. Drugs acting (a) peripherally. (b) centrally, (c) mode of action doubtful. B. Anhidrotics. (a) Drugs acting peripherally, (b) mode of action doubtful. C. Drugs producing a rash on skin when taken internally.

VI. Drugs Acting on the Urinary System: A. Increase quantity of urine. 1. Raising arterial pressure (a) generally, by increased heart action or by general vascular contraction, or (b) locally in kidney, by contracting efferent vessels or dilating afferent vessels. 2. By acting on secreting nerves or renal cells, (a) increasing water, or (b) increasing water and solids excreted. B. Diminish quantity of urine. Toxic effects of certain drugs. C. Render urine acid, *alkaline*. *D. Prevent decomposition of* urine. E. Alter composition of urine, hematuria, changes in color and odor, increase of urea. F. Drugs acting on bladder and urethra.*

Medicolegal

Validity and Construction of Statute Providing for Abatement by State Board of Premises and Occupations Menacing to Public Health

The Supreme Court of Minnesota had for decision, in J. L. McMillan Company vs. State Board of Health, the question of the constitutionality of section 2146 of the Revised Laws of Minnesota of 1905. Section 2143 provides that no person, without the written permission of the board of health of the town, village, or city, shall engage therein in any trade or employment which is hurtful to the inhabitants, or dangerous to the public health. Section 2145 is to the effect that an appeal may be taken from any order of the board to the district court of the county by giving notice and bond as in other cases; if the appeal is taken within twenty days before the time for holding a general term of the court it must be heard at such time and either party is entitled to a trial by jury, but if the appeal is taken more than twenty days before any such term the court shall appoint a time and place for hearing it, for which purpose a jury may be summoned; such appeals shall be tried as in other civil cases, but during their pendency the offense, trade or employment shall not be exercised contrary to the order appealed from, and, if so exercised, the appeal shall forthwith be dismissed. Section 2146 provides that, on written complaint made to the State Board that any person is occupying or using any building or premises within any town, village or city for the exercise of any such trade or employment, it shall appoint a time and place for hearing and give notice of not less than ten days to the complainant and the person complained of, and after such hearing, if, in its judgment, the public health or comfort and convenience require, it may order such person to cease from further carrying on such trade or employment in such building or premises; and after written notice of such order, any person thereafter exercising such trade or employment in said building or premises shall forfeit one hundred dollars for each day after the first to be recovered as provided in the preceding sections. Any person aggrieved by such order may appeal, and said appeal shall be taken and determined in the same manner as prescribed in section 2145. During its pendency such trade or employment shall not be exercised contrary to the orders of the State Board, and on the violation of any such order the appeal shall forthwith be dismissed.

The Supreme Court says that the statute in question is an exercise of the police power of the state, a sovereign power, for the protection of public health comfort and safety by providing for the abatement of premises and occupations which are a menace to the same. It is clearly constitutional unless it is an arbitrary and unnecessarily oppressive use of the power. The company contended that it is an arbitrary and oppressive exercise of the right in that it deprives the parties of their property without due process of law and denies them the right to obtain justice freely. Two specifications were made: The first one was that the statute does not prescribe any proper or just procedure or machinery for taking an appeal, in that there is no provision as to where or in what manner the notice of appeal shall be given, or for a return to the district court, or for framing issues therein. The second, was that the statute arbitrarily so burdens the right of appeal with oppressive and unnecessary conditions as to deprive the party appealing of its property without due process of law, and of its right to obtain justice freely. The court does not concur in this view, but holds the law constitutional.

The procedure provided by the statute is not as impotent as claimed, for it is reasonably adequate. It provides that any aggrieved party may appeal within five days after written notice of the making of the order by giving notice of appeal as in other cases. The usual and well-understood method of giving notice of appeal in such other cases is by serving a written notice of appeal, stating that the party appeals from the order, describing it, on the adverse party or his attorney. In case of an appeal under the statute here in question the adverse party is the Board of Health, the agent of the state, and the notice of appeal, as in other analogous cases, should be served on the president of the board or its secretary and on the attorney general, the chief law officer of the state. If, after an appeal is taken, the board should fail or refuse on proper demand to make return of its proceedings, the district court on due application would compel a return as in other cases. When the appeal is perfected the matter is to be tried and determined on its merits by the court with a jury if either party so demands. It necessarily follows that if the case is of such a character that it is necessary to frame issues for the jury the court may do so in the exercise of its inherent and general powers in accordance with the usual practice in other cases.

A sufficient answer to the argument about the right of appeal being arbitrarily burdened with oppressive and unnecessary conditions is that the right of appeal is neither a natural nor a constitutional right, but a statutory one which the legislature may give or not in its discretion, and if it gives the right it may do so on such conditions as it deems proper. But the claim that the right of appeal given by this statute is burdened with unnecessary and oppressive conditions is not justified by the provisions of the statute. Whether the condition that the nuisance shall not be continued pending the appeal is a reasonable one must not be considered alone from the viewpoint of the dollar mark, but from the viewpoint of public interests as well. It is evident from the language of the statute that the legislature considered the interests both of the individual and the public. The statute does not authorize any interference with the place or occupation which is charged to be a nuisance menacing the public health, until it is determined to be such after ample notice and full hearing. In giving the right of appeal from such determination the legislature was confronted with the fact that to permit the nuisance to continue pending the appeal would be hazardous to the public health, perchance to human lives. In this situation consideration of public health and safety rightly prevailed, but to make the condition of appeal as favorable as practicable the statute made provision for a prompt hearing and determination of the appeal by providing for a special term of court to hear it if necessary.

Application of Statute of Limitations to Action for Malpractice

The Supreme Court of Rhode Island says that what is termed the plaintiff's declaration, in the case of Griffin vs. Woodhead *(74 Atl. R., 417), alleged, in substance,* that the defendant, a physician whom the plaintiff had employed, so unskillfully and negligently conducted himself in the caring of a broken hip that permanent shortening of her leg had resulted. The defense was that the cause of action, if any, was more than two years old, and hence barred by the Rhode Island statute of limitations. This provides, in section 248, that: "Actions for injuries to the person shall be commenced and sued within two years next after the cause of action shall accrue, and not after." Section 249: "Actions of trespass, except for injuries to the person, shall be commenced and sued within four years next after the cause of action shall accrue, and not after." Section 250: "All actions of account, . . . of the case except for words spoken and for injuries to the person, all actions of debt founded upon any contract . . . shall be commenced and sued within six years," etc. The plaintiff claimed that her declaration was based on a contract, and that the period of six years given by section 250 was therefore available for her. But the court takes the view of the defendant, affirming a judgment in his favor, for the reason that it is of the opinion that the provisions of section 248 are so explicit as to the period of limitations for all actions for injuries to the person, whatever may be their form, as to remove any question. For one thing, no exception as to the form of action is made by the section, and, lest it should be supposed that the period of four years allowed in section 249 as to other actions of trespass should be supposed to be inconsistent with section 248, "injuries to the person" are expressly excepted from it. So, too, in section 250. Nor does the court agree with the contention that the statute refers to injuries that result from traumatisms. It finds no such limitations therein expressed, and it has decided that there are many other classes of injuries to the person than those caused by the application of force to the body. Furthermore, to hold that injuries to the person, when caused by a breach of contract, may be sued within six years, would be to create arbitrarily a longer period of liability in certain exceptional cases, such as this case and the case of common carriers, than is established for other cases.

2. **Brain Storm.**—The term brain storm, which is a popular, and not a scientific one, is a phrase, Woodbury states, familiarly used to describe brief states of mental emotional perturbation without reference to their cause. Such attacks, he asserts, may be influenced by atmospheric and climatic conditions to an extent not usually known or suspected. The presumed proximate causes in such cases are only incidental. The real causes lie deeper. Emotional, confusional conditions may occur in apparently normal persons, but are encountered more frequently among the insane. Brain storms, so-called, will be observed more frequently in persons who are neurasthenic and in a depressed vital condition. They are frequently epileptic, or epileptiform. Brain storms as a rule indicate pathologic conditions of the body or mind, but they are symptomatic of general conditions, and are not of specific significance. Violent outbursts of rage or emotion, therefore, have medical importance, and when of frequent occurrence, should be investigated by a physician skilled in mental disorder. In medicolegal cases the phrase brain storm is popularly understood to imply temporary loss of will power, and consequently diminished responsibility on the part of the individual, which is the very point at issue when a case is brought before the court. Woodbury regards the use of figurative and unscientific language by medical witnesses objectionable, since it tends to influence unduly the minds of the jury in weighing the culpability of a prisoner under trial.

4. **Office Gynecology.**—According to McGlinn, there is one field in office gynecology which is being sadly neglected, and that is in the *treatment of retrodisplacement* of the uterus by the use of the pessary. Here the judgment of the physician is put to the test in selecting the type of displacement which should receive such treatment. In old cases, or those associated with adhesions or gross pelvic lesions the pessary has no place, but in the postpuerperal cases which are not complicated and in which there is a good perineum, the intelligent use of the pessary will result in a cure in many cases. McGlinn does not believe in the office introduction of a stem pessary for the cure of dysmenorrhea, sterility or anteflexion.

8. **Tuberculous Ulcers of Stomach.**—The two cases of tuberculous ulcers of the stomach, reported by Ellis, were both secondary to well-marked lesions elsewhere, and illustrate two types of extension of the tuberculous process to that organ. The first case was evidently due to the ingestion of bacilli derived from a pulmonary lesion, the second to extension of the process from the continuous peritoneum. A woman, aged 85, had extensive ulcerative tuberculosis of both lungs and numerous tuberculous ulcers of the ileum and colon. In the *stomach, on the greater curvature, about midway* between the pylorus and the cardia, was a row of eight ulcers, a few of them exceeding one centimeter in diameter. They were all shallow, with slight or no elevation of the margins. In the floor of most of them were gray or yellow tubercles. In addition to these ulcers there were four large conglomerate tubercles that appeared on the verge of ulcer formation. Spreads made from the scrapings of one of the ulcers contained many tubercle bacilli. Sections from one ulcer showed absence of the mucosa and a thickened submucosa, in which were numerous more or less perfect histologic tubercles. Giant cells were occasionally seen but were very few in number. Caseation necrosis was prominent.

A man, aged 25, had chronic adhesive tuberculous peritonitis and multiple tuberculous fistulas in the left inguinal and trochanteric regions. On the greater curvature of the stomach slightly nearer the cardiac end, was an indolent ulcer, 3.5 by 5 cm. Four and six centimeters respectively from the cardia were two ulcers, 1.5 and 2 cm. respectively, in diameter, that perforated when adhesions to surrounding structures were separated. On the posterior wall, eight centimeters from the cardia, was an ovoidal, elevated mass, 1.5 cm. in diameter, that was cyst-like in consistency. Puncture through the overlying mucosa showed the content to be a thick, yellowish fluid, in stained smears of which were numerous tubercle bacilli. On the serous surface of the stomach, opposite to each of the lesions described, as well as scattered irregularly over the entire organ, were numerous tubercles of various sizes. The omentum, mesentery, pancreas and spleen were adherent to the stomach, and the coils of intestines were matted into an inseparable mass.

16. **Letter to a Neurologist.**—Collins describes the letter of a mother whose son has disappointed her and his father, by becoming the victim of the periodic drink habit. He has reached the age of 35 without being cured or having any absorbing interest in life. The neurologist tries to show the mother that she must give her son some interest in life sufficient to fill his mind and prevent him from desiring the solace of the cup that inebriates. He shows that the condition is one of a lack of education in ambition, and a desire to do something worth while in the world.

17. **Fear in Preventive Medicine.**—Reasonable fear saves many lives and prevents much sickness, says Rosenau. It is one of the greatest forces for good in preventive medicine, and at times it is the most useful instrument in the hands of the sanitarian. It is often the fear of a disease that gives the health officer the ways and means to combat it. Because we fear cholera, we have none of it in the breadth and length of the United States; we have no fear of typhoid and that is why it is endemic. A case of cholera in any of our cities to-day would at once be placed *incommunicado*, under the strictest quarantine. The sick room would be screened against flies, the dejecta would be disinfected, the nurse and the physician would be isolated, or they would be required to take most exacting precautions, gallons of germicides would be spilled and fumigants burned galore to proclaim the energy of the sanitary department. The neighborhood would be searched for secondary cases to nip them in the bud. Finally, the convalescents would not be given their liberty until the danger of bacillus carrying had passed. By strange contrast, little attention is paid to a case of typhoid in the neighborhood, or even in the same house. Still less regard is ordinarily given to the dangers of typhoid infection on a dairy farm, or in a butcher's shop or bakery, or other places where foodstuffs are handled. It is the lack of fear of yellow fever that permits it to smolder in an endemic focus, just as the lack of fear of typhoid permits it to smolder in Boston, Philadelphia, Washington and other American cities. A sharp epidemic of typhoid is a good life saver. The fear it instills builds filter plants, spends money, and awakens energy for other necessary and expansive sanitary improvements. It is the fear of tuberculosis rather than the pity of it all that prompts legislatures to build sanitaria and establish clinics and to appropriate large sums of the people's money for the control of this disease of defective civilization.

35 Dangers of Prolonged Anesthesia. C. A. Finley, Galesburg.

29. **New Pure Food Catsup.**—Wesener sums up his paper as follows:

1. Sodium benzoate and benzoic [illegible] less active than the other substances used in [illegible] ood, and the benzoate is less active than the [illegible] l in making the pure food catsup, which it has been stated may be made without the use of chemicals.
2. By the use of sodium benzoate and benzoic acid, the flavor of the article preserved is not lost nor can any inferiority of the product be disguised.
3. The flavor produced by vinegar and spices is wholly artificial and does not retain much of the natural flavor of the product that is preserved. By this means it is easy to cover up inferiority and thereby deceive the consumer.
4 Changed conditions in economics have made it imperative for the manufacturer to prepare his food to reach the consumer in a sweet, wholesome and palatable state.
5. Sodium benzoate and benzoic acid for catsup do this far better and in a less injurious manner than the products that are now used and so extensively advertised in the manufacture of pure food catsup.

48. Abstracted in THE JOURNAL, July 31, 1909, p. 409.

54. **Anastomosis Between Sigmoid and Rectum.**—The procedure employed by Balfour may be described as follows:

1. The patient is placed in a high Trendelenburg position and a long median incision made between the umbilicus and pubes.
2. The intestines are carefully packed off above, leaving only the lower sigmoid exposed in the pelvis.
3. The affected portion of the bowel is liberated by lateral incisions through the peritoneum, especially through the outer leaf of the sigmoid, and a semilunar incision is made along base of bladder connecting the two lateral incisions.
4. Careful dissection is made of all the fat and glands as high as the abdominal aorta, the hollow of the sacrum being swept clean.
5. The inferior mesenteric and middle sacral arteries are ligated at proper points.
6. Two pairs of forceps are clamped on the bowel at a suitable distance below the tumor and two on the proximal side; the necessary amount of sigmoid with the tumor is excised, and the cut ends are sterilized.

A three-quarter inch rubber tube is passed into the lower segment of bowel until the end protrudes through the anus; the upper end with lateral eye is inserted into the proximal end of the sigmoid to a distance of some three inches. It is here secured by a transverse catgut stitch one-half inch above the cut end of the intestine.

8. Traction is made by an assistant on the end of tube projecting from the rectum, until the cut ends of the bowel meet, and the anastomosis is made by interrupted [illegible] catgut sutures with careful coaptatior [illegible]
9. Traction is again made on the tr[illegible] half-inch intussusception, this being aided by a few forceps on the distal fragment to steady it, and a second row of sero-muscular sutures is inserted.
10. The defect in the peritoneum behind, is remedied by sliding peritoneum and suturing, and finally the omentum is drawn down over the anastomosis, and if necessary secured by a catgut suture.
11. The abdominal wound is closed in the usual way. The rubber rectal tube remains in position about six days, or until the catgut suture is absorbed.

55. **Excision of Rectum.**—Peck claims that the perineal operation is considerably shorter and less severe than the combined operation and is applicable to a large number of low-lying growths. By leaving the bowel closed for from 2 to 5 days or even longer, healing without infection of at least the greater part of the wound can be obtained in many cases. Clean healing, by preventing inflammatory infiltration of the tissues about the sphincter, is probably a great aid in preserving a fair degree of control. The splitting of the anal segment posteriorly enables one to leave the anterior attachments of the sphincter undisturbed, and thus to protect at least a part of its nerve supply.

56. **Arteriovenous Anastomosis.**—Muller's patient had a gangrenous fifth toe, and gangrenous patches on the remaining toes. Under spinal anesthesia, end-to-end anastomosis was effected, by the Carel method, of the femoral artery and vein at the apex of Scarpa's triangle below the origin of the profunda femoris. Complete reversal was not attempted. The artery was moderately sclerosed. When the clamps were removed the vein was seen actively pulsating and continued to do so during the closure of the wound with catgut for the deeper tissues, silkworm gut for the skin. The leg and foot became warm, the leg red and the foot reddish purple in color. No visible pulsation of the veins was observed.

In 48 hours the foot was cold to the ankle, the leg being warm. On the third day a line of demarcation began to appear at the tibiotarsal joint. This became more marked in a few days and amputation at the middle third of the leg was advised, but the patient refused to have it done. For days the patient was absorbing toxin from the gangrenous foot and was gradually getting weaker. Then he became delirious and, permission being obtained from his relatives, the leg was amputated 4 inches below the knee. At this time, the posterior tibial and peroneal veins showed feeble but distinct spurts of blood. There were many unusually sharp oozers. The anterior tibial artery did not bleed. All the arteries and the external saphenous vein were thrombosed. The internal saphenous vein was patent. The flaps were loosely sutured together and drainage provided. There was much suppuration in the flaps, and despite energetic systemic stimulation, death occurred, apparently from exhaustion, nine weeks after the first operation.

81. **Work of the Chicago Juvenile Court.**—The main points in Churchill and Britton's paper are, briefly, the following: The children brought before the Chicago Juvenile Court, in the early years of their dependency, differ little in their physique from children living under more favorable conditions. The boys, as a rule, are taller, but less well-nourished and of smaller chest capacity. The girls are inferior in height, weight and chest capacity. The boys, in the latter half of their dependency, *e. g.*, from 9 to 12 years of age, and throughout their delinquency, are inferior in all respects, and their inferiority is more marked after the age of puberty. The same comment holds true for the girls during these same periods, until they reach 16, when they are equally as tall as, *and far heavier than, their more fortunately surrounded* mates, which superiority in physique, by its very attractiveness, is one of the main factors in causing their delinquency. All the children of both groups are remarkably free from organic disease. Considerable numbers present drawbacks to perfect physical health in the shape of enlarged tonsils, and probably adenoids, carious teeth, enlarged cervical glands and diseases of the ear. A small proportion, about one-sixth, have trouble with the eyes. This defective vision and the deafness resulting from enlarged tonsils, adenoid growths and ear disease, are defects more or less predisposing to delinquency by rendering school work more difficult, and the street life with its attendant evils, more easy and more attractive. The frequency of gonococcus disease among the older girls is merely an index of the prevalence of this infection among this particular class as a whole. The generally lowered tone of the delinquents, as manifested by diminished height, weight and chest capacity, probably plays *no part* in the production of delinquency, but is rather a result of the general life led by these children, the result of common causes leading also to mischievous, delinquent conduct, viz.: bad air, poor food, bad surroundings, smoking, drinking, etc.

95. **Recognition of Tricuspid Disease.**—Stern is of the opinion that many instances of organic disease of the segments as well as of muscular or relative incompetence of the tricuspid valve are overlooked. When a patient is on his back and there is any tendency of distention of the jugular veins it will be evinced there and then. By lowering the head of the patient while he is still on his back, the jugular

veins become more distended, as a rule, and may begin to pulsate. Distention of the vein, or its pulsation, will increase in direct ratio to the lowering of the head, but when a certain point is reached, which is dependent on individual factors, the pulsation diminishes more or less and the engorgement may also recede. This lowering of the head, which in reality is but an extension, a stretching of the muscles of the neck, the veins, etc., is reflected in the tricuspid area, where murmurs are now noticed that were not perceptible before or which have been quite indistinct. The murmurs elicited while the patient is in this posture may be determined in accordance with the point of maximum intensity and the direction of transmission.

The examiner should stand behind the patient somewhat to the right of the head of the latter when an examining table is utilized. In case the examination is made in bed, the physician should be sitting at the right side of the head of the patient, who has been placed across the bed. In both cases the head of the patient should be supported by either the left hand of the examiner, or in advanced cases by both hands of an attendant. It should not be dropped at once over the edge of the examining table or bed, but should be brought down very gradually and be immediately elevated as soon as the dyspnea and the venous engorgement become excessive.

96. **Hemolytic Test in Cancer and Tuberculosis.**—It seems that in the blood serum of some cases of malignant disease—those generally associated with anemia and loss of weight—there exists a hemolytic property for alien red cells. It also appears that while this fact is interesting and may be of value in certain individual cases, similar manifestations are possible from the sera of patients non-cancerous. Smithies calls attention to this manifestation in cases of tuberculosis, syphilis and other disease conditions. It is noted, however, that the conditions in which this direct hemolysis is obtained are those frequently associated with anemia, loss of weight and cachexia. He has not noted that the reaction of reverse hemolysis mentioned by Crile as occurring in 92 per cent. of cases of tuberculosis is characteristic. It occurs occasionally, but is by no means characteristic, inasmuch as it also occurs in malignant disease, syphilis and other diseases. Smithies' work also shows that the transfusion of blood from one individual to another in cases of emergency is a dangerous procedure unless previously the hemolytic reactions of the two sera have been noted. In conclusion, he emphasizes that while the main mass of data is at present against the hemolytic reactions being characteristic for any single class of disease, yet the large number of cancer cases showing this reaction should urge us to seek modifications of the method in the hope that study of various sera along other lines will lead to the firm establishment of a specific reaction for cancer and other disease conditions which seem to have specific pathology.

100. **Examination of Spirochæta Pallida.**—The method described by Williams depends on two principles: First, that there are many spirochetes on the surface of every syphilitic ulcer, and second, that these show a preference for liquids, exhibiting a tendency to leave their host with the drawing off of certain liquids, properly applied. Williams first teases the surface of a mucous patch or cutaneous ulcer with a toothpick, or if he is dealing with a papule or chancre he scrapes it gently with a sharp scalpel. The fluid, a warm physiologic salt solution, is quickly dropped on the surface and as quickly withdrawn for examination. If the spirochetes are to be examined in motion, the salt solution should be warm when the suspension is made and examination done at once. This technic carried out in detail has enabled Williams to find dozens of spirochetes in one field. He is usually able to make a diagnosis in six minutes.

101. **Metallic Tinkling in Hydropneumothorax.**—In the light of experiments performed, Barach says that metallic tinkling in hydropneumothorax is produced most typically, and in all probability most frequently, by the escape of a bubble of air from the fistulous opening of a diseased lung, below or at the level of the liquid. When metallic tinkling is heard as the result of a bubble of air coming up through the effusion, the sound is not produced at the bursting of the bubble on the surface of the effusion, but with the separation of the bubble from the fistulous opening of the lung. Metallic tinkling can be produced by a bubble arising from the moist surface of a perforated lung above the level of the liquid, if the bubble is expelled with sufficient force. The characteristic qualities of the tinkling sound are determined by the density and size of the ring forming the fistulous opening, the expulsive force behind the bubble, the proportion of air and liquid in the chamber, the size and directness of the avenue of communication between the resonating chamber and the external atmosphere. Judging by the results of these experiments, Barach believes that the first three are the most potent factors in the production of typical metallic tinkling in hydropneumothorax. Metallic tinkling as heard in the chest is probably never caused by falling drops, an explanation which to the present has received the widest endorsement.

114 *Physician's Relation to the Family in Prevention of Venereal Diseases. C. J. Luytics, St. Louis.
115 Venereal Diseases and the Social Evil. H. J. Scherck, St. Louis.

110. **Effect of Venereal Diseases on Women and Children.**—According to Bishop, 75 per cent. of all special and surgical operations performed on women are necessary because of gonorrheal infections. Thousands of women are not included in these figures because they do not come under surgical care, yet drag out a living death. Gonorrhea is credited with 80 per cent. of all inflammatory diseases peculiar to women. Of women infected by gonorrhea, 50 per cent. are rendered absolutely sterile; many others with gonorrheal infection are rendered sterile after birth of the first child—"one-child sterility." Sterile marriages are more often the result of incapacity than of choice. Syphilis has slain its thousands; 70 per cent. of children born of syphilitic parents died either before or shortly after puberty. Those who survive are often physical weaklings. The economic factors involved in the loss of health, of life, which these few but telling and undoubtedly conservative figures indicate, are items to be considered. The enormous outlay for medical and hospital care, the inability of women to be true homemakers because of impaired health, the discontent and discouragement because of sterility, the passing of domestic happiness, divorce—the real reason of which in many cases is the social disease—all indicate that these contagious and therefore preventable diseases should be studied both by the medical profession and the laity, and included in all public health education work.

112. **Influence of Venereal Diseases on Conception and Heredity.**—Taussig calls attention to one point often overlooked. Many of these women who are not infected at once, have one child and then become sterile. In fact, this "one-child sterility" as it is called, is considered by many to be characteristic of gonorrheal infection.

114. **Physician's Relation to Family in Prevention of Venereal Disease.**—The family physician as medical adviser, holds

56. **Arteriovenous Anastomosis.**—Muller's patient had a gangrenous fifth toe, and gangrenous patches on the remaining toes. Under spinal anesthesia, end-to-end anastomosis was effected, by the Carel method, of the femoral artery and vein at the apex of Scarpa's triangle below the origin of the profunda femoris. Complete reversal was not attempted. The artery was moderately sclerosed. When the clamps were removed the vein was seen actively pulsating and continued to do so during the closure of the wound with catgut for the deeper tissues, silkworm gut for the skin. The leg and foot became warm, the leg red and the foot reddish purple in color. No visible pulsation of the veins was observed.

In 48 hours the foot was cold to the ankle, the leg being warm. On the third day a line of demarcation began to appear at the tibiotarsal joint. This became more marked in a few days and amputation at the middle third of the leg was advised, but the patient refused to have it done. For days the patient was absorbing toxin from the gangrenous foot and was gradually getting weaker. Then he became delirious and, permission being obtained from his relatives, the leg was amputated 4 inches below the knee. At this time, the posterior tibial and peroneal veins showed feeble but distinct spurts of blood. There were many unusually sharp oozers. The anterior tibial artery did not bleed. All the arteries and the external saphenous vein were thrombosed. The internal saphenous vein was patent. The flaps were loosely sutured together and drainage provided. There was much suppuration in the flaps, and despite energetic systemic stimulation, death occurred, apparently from exhaustion, nine weeks after the first operation.

81. **Work of the Chicago Juvenile Court.**—The main points in Churchill and Britton's paper are, briefly, the following: The children brought before the Chicago Juvenile Court, in the early years of their dependency, differ little in their physique from children living under more favorable conditions. The boys, as a rule, are taller, but less well-nourished and of smaller chest capacity. The girls are inferior in height, weight and chest capacity. The boys, in the latter half of their dependency, *e. g.*, from 9 to 12 years of age, and throughout their delinquency, are inferior in all respects, and their inferiority is more marked after the age of puberty. The same comment holds true for the girls during these same periods, until they reach 16, when they are equally as tall as, and far heavier than, their more fortunately surrounded mates, which superiority in physique, by its very attractiveness, is one of the main factors in causing their delinquency. All the children of both groups are remarkably free from organic disease. Considerable numbers present drawbacks to perfect physical health in the shape of enlarged tonsils, and probably adenoids, carious teeth, enlarged cervical glands and diseases of the ear. A small proportion, about one-sixth, have trouble with the eyes. This defective vision and the deafness resulting from enlarged tonsils, adenoid growths and ear disease, are defects more or less predisposing to delinquency by rendering school work more difficult, and the street life with its attendant evils, more easy and more attractive. The frequency of gonococcus disease among the older girls is merely an index of the prevalence of this infection among this particular class as a whole. The generally lowered tone of the delinquents, as manifested by diminished height, weight and chest capacity, probably plays no part in the production of delinquency, but is rather a result of the general life led by these children, the result of common causes leading also to mischievous, delinquent conduct, viz.: bad air, poor food, bad surroundings, smoking, drinking, etc.

168 *Distribution of Antibodies and their Formation by the Blood. L. Hektoen and A. J. Carlson, Chicago.

166. **Venom Hemolysis.**—Kyes emphasizes the following points: There is present in all venoms a hemolysin existing as one of a number of distinct toxins; this hemotoxin affects hemolysis only in conjunction with a so-called complementing substance which, however, may be found within the erythrocytes; so far as at present recognized the activating substances are lecithins. The reaction between the hemotoxins and lecithin is essentially a chemical reaction resulting in the formation of a complete lysin, and this complete lysin is a true toxin in that it stimulates the production of a specific antitoxin.

167. **Malaria and Intracorpuscular Conjugation.**—The importance of intracorpuscular conjugation, aside from biologic interest, lies in its relation to prophylaxis, because if the conjugating organisms are the cause of relapse, it is necessary that treatment be instituted promptly and hence that infection be recognized as early as possible. The early recognition of malarial infection rests on microscopic examination of the blood, which should never be neglected in any patient suffering from fever. The prophylaxis of malaria especially in regions in which this disease is rare, usually rests with the attending physician, because the early recognition of the disease and the prompt institution of proper treatment will effectually stop its spread so far as that patient is concerned. A false diagnosis or improper treatment will result in the patient becoming a source of infection to the community in which he resides.

178 Extreme Malocclusion of the Teeth with Description of the Measures Taken for its Relief. J. S. Ibbotson, Montreal.

174. **Apparatus for Rectal Anesthesia.**—The apparatus devised by von Eberts consists of an outer jar (in this case a galvanic cell) containing an ether bottle, the space between the cell and the bottle being filled with water at a temperature of 90° F. Through the rubber cork in the bottle is passed a long glass tube connecting with an ordinary cautery bulb, while the second perforation in the cork is occupied by a short tube which provides for the exit of ether vapor. Between the bottle and the rectal tube is introduced a T-tube for the rapid relief of tension within the bowel or the attachment of an oxygen supply. Should the ether tend to rise in the bulb tube through back pressure, a pair of hemostatic forceps should be applied between the bulb and the bottle. The metal ring placed in the bottom of the jar not only holds the ether bottle in position but diminishes the chances of breakage when hot water is passed into the jacket. The metal cap provides passage on one side for the thermometer and on the other for a funnel when the addition of hot water is found necessary.

177. **Stab Wounds of Liver.**—In this case there were two parallel stab wounds just internal to the right nipple. They were two inches long and extended from the lower margin of the fourth rib down and inward in the direction of the external intercostal muscle. On reflecting the pectorals the fifth rib was found cut through twice, just internal to the costo-chondral junction. One cut was ¼ inch internal to the other and a small wedge of cartilage was cut out cleanly *in situ*. In the right pleura was a small amount of fluid blood. The right lung was healthy, slightly collapsed and showed no injury of any kind. The other thoracic viscera were normal. The diaphragm on the right side showed about the middle and corresponding in direction with the external wounds, an incision 2 inches long, the lower angle of which was 3½ inches away from the costo-phrenic junction in a straight line. In the abdomen was fluid and clotted blood. The right lobe of the liver was found to be stabbed right through from the diaphragmatic to the inferior aspect. The wound on the inferior surface was 1½ inches long and was situated just to the right of the foramen of Winslow. The cystic duct was nicked at the inner end of the wound. There was no damage to any part of the abdomen. The points of special interest are: (1) That the knife should have completely missed the right lung; (2) that a knife which made a wound 1½ inches long on the inferior surface of the right lobe of the liver in the position above detailed should have done no harm to the duodenum or upper pole of the kidney.

1. **Streptotrichoses and Tuberculosis.**—After considering in some detail the general characteristics of the streptotricheæ and the pathology of the infections which they cause, Foulerton deals with the evidence which is available in support of these two propositions: (1) That under the name of "tuberculosis" there are commonly included infections caused by more than one species of parasite; and (2) that the parasites, generally reputed to be bacilli, which are the cause of tuberculosis, belong in reality to a higher group of organisms and should as streptotricheæ be included with the hyphomycetes, or mould fungi. This class of infections has a wider interest because of the apparent affinity between certain undoubted species of streptotricheæ and the parasite, or parasites, of tuberculosis. Foulerton's investigations into the pathology of streptothrix infections, together with much work bearing on the subject which has been carried out elsewhere, have led directly to a very definite conclusion as to the relationship, amounting to actual generic affinity, between this class of infections and those recognized under the name of tuberculosis. And further, systematic comparison of the biologic characteristics of the recognized streptothrix organisms on the one hand and of different "strains" of the parasite of tuberculosis on the other, he says, leaves no doubt as to the correctness of the opinion held by certain earlier pathologists who, within a few years of Koch's announcement of his discovery of the cause of tuberculosis, maintained that the reputed bacillus was not a fission fungus at all, but rather belonged to a higher group of mould fungi.

4. **Treatment of Serous Pericardial Effusion.**—West holds that paracentesis is rarely necessary, for serous effusions in the course of rheumatic fever usually disappear spontaneously, [illegible]ften produce no urgent symptoms. Absorption, when it

once begins is rapid, more rapid than in the pleura. The effusion is, no doubt, removed in the same way, by the lymphatic pump, worked by the respiratory movements on the one side and by the cardiac on the other. Exploratory punctures may be made in any place if the physical signs suggest it. In an ordinary case, when the diagnosis is clear and there is choice of place given, the sites selected and advocated have been four: 1. In Sibson's notch—*i. e.*, in the third left intercostal space near the sternum—a dangerous place on account of the proximity of the left auricle. 2. In Rotch's angle, in the fifth right intercostal space, to the right of the sternum—another risky place, because the right auricle cannot be far away, even if the effusion be of large size. 3. The fifth space to the left of the sternum. This spot is advocated because the puncture is made in the spot which is not covered with lung, and so the pleura is not perforated. Though this may be a good place for trephining the thorax with a view to incising the pericardium, it is not the best place for paracentesis. Nor need the risk of puncturing the pleura with the needle or with a fairly large trocar and cannula be seriously considered. In paracentesis the mere perforation of the pleura on the way to the pericardium does no harm. 4. The safest place is the fifth or sixth intercostal space outside the lept nipple line, but well within the area of the dulness, for here, owing to the displacement of the heart upward and the distention of the pericardium outward, is the widest space between the heart and the seat of puncture. All the fluid that can be obtained should be removed. Often it does not reaccumulate, but if it should a second and third paracentesis may be performed or as many as necessary.

5. **Singular Combination of Fractures of the Leg.**—The case reported by Lane illustrates the association in the same subject of an abduction fracture of the ankle-joint, or, as it is more commonly called, Pott's fracture, with a spiral or torsion fracture of the tibia. The patient, in an athletic mood, arranged to jump over a flower-bed. He slipped, twisting his foot very painfully as he approached it, and apparently leaping off the normal leg landed on the damaged one which he felt break with his weight. Lane regards it as being clear that the spiral fracture of the lower end of the fibula was broken by the excessive abduction of the foot, while the tibia yielded to the torsion to which it was exposed when he landed on the foot already over-abducted because of the fracture of the fibula.

6. **Patent Urachus and Encysted Urinary Calculi.**—The patient was apparently healthy apart from his urinary complaint, which dated back some five years or more. Several small concretions lay free on the base of the bladder but on commencing to crush the first, the beak of the lithotrite impinged on what appeared to be a much larger calculus occupying a position at the apex of the half-distended bladder. After the first stone had been crushed the projecting portion of this larger calculus was easily seized between the blades of the lithotrite, but was found to be fixed to the bladder wall. To crush this calculus *in situ* appeared dangerous, if not impossible, so Dykes performed lateral lithotomy, and the forefinger passed into the bladder. The calculus was now found just within reach of the finger. With the forefinger on the tip of the calculus, and the other hand on the abdominal wall it was estimated to be of considerable size, and its upper portion seemed very close under the examining hand beneath the abdominal wall in the middle line. It was evidently an hour-glass stone, the deeper half being considerably larger than the projecting portion felt by the finger. The projecting portion being steadied in the grasp of lithotomy forceps the perforated end of a long probe was insinuated alongside the neck and gradually maneuvered round the whole circumference, loosening the retaining tissues till by gentle traction and rotation of the forceps an "hour-glass" calculus was safely delivered. A second calculus immediately dropped from the same pocket into the bladder cavity. It, together with the three small concretions, the presence of which on the bladder floor had already been detected, was now removed, and the debris of the small stone first crushed, washed out. In case other concretions might still be lying in the pocket, its recesses were explored by a probe. Nothing further was found, but the probe passed up in the middle line, easily palpable through the abdominal wall to a point two inches below the umbilicus. At the upper end the pocket seemed to be contracted to a mere sinus. Convalescence was rapid and uncomplicated.

7. **Obstruction of Small Intestine.**—This case is of some interest from the points of view of diagnosis and pathology. The history provided none of the special features of obstruction from a Meckel's diverticulum, except the obviously mild nature of the constriction, since flatus was passed throughout. On the other hand, the history of the initial pain and malaise, continuing for two days, followed by the development of vomiting and constipation, suggested an attack of perforated appendicitis, while this theory was supported by the character of the abdominal distention, the tendnerness beneath the left rectus, and the fulness in Douglas' pouch, all of which suggested that the obstruction was symptomatic and depended on the presence of pus in the pelvis. The pathologic interest Makins believes lies in the fact that the condition forms another link in the chain of resemblance between the possible accidents to which both Meckel's diverticulum and the appendix are alike liable.

9. **Cocain Poisoning.**—In this case the symptoms of poisoning manifested themselves after two applications of a 2 per cent. solution of cocain to the throat and tonsils made within an hour.

10. **Influence of Narcotics on Phagocytosis.**—From experiments performed by him, Reynolds concludes that morphin exerts a marked influence on the leucocytes. Not only does it check diapedesis, but phagocytosis is diminished in a marked degree. The growth of bacteria, on the other hand, is not appreciably affected. What bearing has this on the practice of medicine and surgery? It is probable that in most surgical operations a certain number of pathogenic organisms gain entrance to the wound, however carefully asepsis be observed. The further history of the case turns on this point. Will the phagocytes be able to destroy these bacteria before the latter have multiplied sufficiently to gain the upper hand? If morphin temporarily paralyzes the activity of the phagocytes, if this drug be given time is lost during which the bacteria multiply. When the narcosis passes off the phagocytes may be unable to destroy the bacteria on account of their number and the paralyzing effect of the toxins produced by them; in fact by giving the morphin the chances of sepsis have been increased.

17 *The Intestinal Stitch. E. K. Herring.
18 The Cerebellum and its Diseases. J. S. R. Russell.

12. **Conditions Simulating Dyspepsia.**—Hutchinson describes cases in which the patients are believed to be suffering from gastric disorder when they are either not so at all or only secondarily, the gastric symptoms being due to some other disease, proving that when a patient complains of gastric symptoms, the other organs must also be investigated.

13. **Medical Treatment of the Poor.**—The proper feeding and rearing of pauper children, the control of boy labor, the decasualization of labor, labor bureaus, unemployment insurance, detention colonies for the vicious and the lazy, and for weak-willed ne'er-do-wells, the safeguarding of imbecile or feeble-minded young women by similar detention, the enforcement of every practical check on alcoholic indulgence—all these and other agencies have to be thought of as part of any sufficient plan of reform. Improvement in the general conditions of life and work resulting from such measures would quickly add to the numbers who would be in a position to become paying members of provident institutions. So long as human nature remains what it is, no panacea for all its defects can be found, but the simultaneous operations of agencies regarding whose value there is practically unanimous agreement, will do much in the desired direction. One of

these agencies will be better preventive and curative medical treatment of the poor, and in whatever way that be achieved, consistently with the preservation of individual responsibility, it will play an important part in the advancement of the national welfare.

15. **Afebrile Erysipelas.**—The two cases reported by Macauley appear anomalous in that in both the temperature was for the most part subnormal and in both the cerebral symptoms were early and profound. The latter manifestation was perhaps due to the fact that there was very little effort on the part of either patient to combat the disease—the one being an elderly man of enfeebled constitution, and the other an infant 3 weeks old. The diarrhea in one case also appears unusual, constipation being the rule. It probably indicated a profoundly toxic condition.

17. **The Intestinal Stitch.**—Herring attempts to show that the Lembert, Cushing and Halstead intestinal stitches are theoretically at fault. Experience teaches that they will each make a good union, but that is not the point. These faulty methods, he declares, should be banished or else put quietly into the background and some stitch more nearly approaching the ideal given the place of honor. He lays down four fundamental principles which must be carried out in every method of stitching which aims at the ideal: (1) The stitches must not tear through; (2) broad surfaces of union must be brought together evenly; (3) the stitches must be buried; (4) the application must be simple. He pictures such a stitch.

36. **Time Required for Passage of Food Through Infant's Gastrointestinal Tract.**—About 1 grain of pulverized carmin was given to the infants as they were nursing, and the time of the appearance and disappearance of the stain in the stools was recorded. The infants were between 4 days and nearly 3 months old and were breast-fed and normal. The stools may show the stain in from 3 to 10 hours, and the stain may persist for a variable time; it never lasted longer than 21 hours in 8 of the 10 tests reported. The method is valuable for marking the stools from a certain feeding.

37. **Pseudoachondroplasia.**—The girl of 14 in the case reported presented a malformation with certain points in common with and others differing from true achondroplasia, dysplasia of the bones and what is called fetal rachitis.

39. **Lymphosarcoma of the Glands and Testicles.**—Lereboullet reviews the clinical data and autopsy findings in the case of a boy of 14 with malignant degeneration of both testicles, the histologic features of which do not concord with any known species of cancer. The inflammatory and sclerous elements associated with the neoplastic tendency, the prevalence of giant cells and the positive response to the cutaneous and intradermal tuberculin tests, suggest that tuberculosis may have been the primal cause of the lymphosarcoma in this case. The localization of the lymphosarcoma in the testicles and dura mater induced a special and deceptive syndrome, the numerous tumefied glands and spasmodic paraplegia suggesting an unmistakable tuberculous affection at first until microscopic examination of an excised gland threw doubt on its tuberculous character. The case was finally classed as an instance of the neoplastic reaction of the tissues to the tubercle bacilli to which Gougerot has recently called attention in his work on non-follicular bacillotuberculosis. Tollemer has reported a case of lymphosarcomatosis starting in the tonsils in a girl of 9, which terminated fatally in 2 months, but with nothing to incriminate the tubercle bacillus.

41. **Diagnostic Importance of Alkaline and Acid Reactions of Infants' Stools.**—Triboulet has been testing the reaction of

infants' stools in a large number of cases, and has found that the stool of the normal breast-fed infant gives an acid reaction; a neutral or an alkaline reaction should be regarded as an index of pathologic conditions. The stool of the bottle-fed infant, on the other hand, is alkaline. A neutral or acid reaction with a bottle-fed infant, he asserts, indicates defective digestion. The digestive disturbances may be of various kinds, but the liver functioning is generally more or less at fault. It is this insidious insufficiency on the part of the liver, he says, which is responsible for so much of the acute disturbance in the serious toxi-infectious diseases, typhoid, pneumonia, etc. Reviewing the experiences at the clinic with measles in infants during the last year, he found an abnormal reaction in 91 per cent. of the fatal cases of measles; in 64 per cent. of the serious cases terminating in recovery, but in only 10 per cent. of cases of the mild forms of the disease. The predominance of an alkaline or acid reaction in the stools, corresponding to breast or bottle feeding, can thus yield important information in regard to the prognosis, etc. The tests are made with litmus paper.

42. **Ulceration of Iliac Vessels in Contact with a Drain Tube.**—Savariaud adds 7 new cases to one he has found on record in which the iliac artery or vein or both ulcerated in consequence of contact with a drain. Fatal hemorrhage resulted in some of the cases. Even a soft drain resting lightly on the vessels is liable to do harm.

43 *Superheated Air in Treatment of Gangrene. (Gangrène du pied et de la jambe chez un homme agé et diabétique.—Artérites oblitérantes.—Heureux résultats des applications de douches d'air surchauffé à tres haute température.—Appareil aéro-thermogénérateur.) M. Dieulafoy.

February 19, No. 15, pp. 129-136

44 Acute Chorea and Psychic Disturbances. Rémond and Voivenel.
45 Galvano-Ionic Medication. J. Larat.

43. **Superheated Air in Treatment of Gangrene.**—In one case reported, the patient was a man of 64, diabetic for 20 years, and the gangrene of the leg was evidently the result of obliterating arteritis. As the urine contained 27.45 gm. of sugar and 13.92 gm. of acetone to the liter, and the pulse was weak and at 140, amputation was out of the question. The patient's strength was kept up by yolks of eggs in bouillon, given by the spoonful, with other suitable measures, alkalines, etc., and a jet of superheated air was played on the gangrenous limb. The aero-thermo-generator, as Dieulafoy calls the apparatus devised for the purpose, is attached to the electric light wire. It can heat the air to 700° C. and force it out in a strong jet. After a week's application of the hot air douches, with the air at 300° C. on the gangrenous parts and 80 to 100° on the sound parts, each daily sitting lasting from 30 to 45 minutes, conditions began to improve and by the end of the third month the local and general improvement had reached a point when amputation could be successfully done. The hot air practically cooked the tissues, keeping the gangrene dry and the tissues mummified. The applications were not very painful, the patient standing them well. In a second similar case not treated with the hot air, the gangrene was oozing and the process became infected, causing threatening complications. The hot air treatment, the author asserts, prevents such secondary mishaps. The lesions of obliterating arteritis and senile changes seemed to be identical in both cases.

Revue de Chirurgie, Paris

February 10, XXX, No. 2, pp. 135-326

46 *Technic of Colopexy for Prolapse of the Rectum. E. Quénu and P. Duval.
47 *Echinococcus Disease in the Lung. (Kystes hydatiques du poumon.) Tuffier and J. Martin. Commenced in No. 1.
48 *Hematoma in the Mesentery. (Les kystes sanguins du mésentère.) L. Timbal. Commenced in No. 1.
49 *Modern Treatment of Popliteal Aneurisms. (Revue critique sur le traitement moderne des anévrismes poplités.) E. Quénu and C. Muret.

46. **Colopexy for Rectal Prolapse.**—Quénu and Duval give an illustrated description of the technic they have applied in 3 cases with satisfactory outcome, urging the superiority of the colopexy over other means of correcting prolapse of the rectum of abdominal, congenital origin. When the prolapse is of perineal origin, suture of the levator muscles, combined with recto-syndesmopexy, according to the technic previously described by Quénu, answers the purpose. With the colopexy the pouch of Douglas is obliterated and then a row of sutures is applied to fasten the pelvic colon to the rear aspect of the bladder, to the left pelvic peritoneum and the iliac peritoneum.

47. **Echinococcus Disease of the Lung.**—Tuffier and Martin present data to demonstrate that echinococcus disease of the lung may present itself under the guise of tuberculosis, pleurisy or pneumonia; there is no pathognomonic sign but presumptive evidence is afforded by polycythemia with from 5,800,000 to 6,890,000 reds and 10,000 or 15,000 whites—polynuclears with eosinophilia of 4 or 8 per cent. Roentgen-ray examination confirms the presumption of a hydatid cyst as also fixation of complement in the hemolytic test. Without operative intervention fully half the cases of echinococcus disease of the lung terminate fatally, and the proportion of fatalities is even larger in the cases in which puncture is the sole reliance. The most favorable results may be counted on when the cyst is still closed. The authors have been unable to find on record any cases in which pneumotomy was required a second time for a hydatid cyst of the lung. They give brief details of 35 cases in which pneumotomy was done, including Steck's case reported in The Journal in 1898. There are only 2 deaths in the list and in one of these cases the cyst was not found; the patient in the other case succumbed to hemoptysis two months after pneumotomy for a suppurating cyst in the base of the right lung.

48. **Mesenteric Blood Cysts.**—Timbal concludes his article on this subject by extolling the method of opening the cyst and suturing the lips to the wound—marsupialization. He compares the results obtained by puncture, extirpation and marsupialization and reviews the symptoms and course. The tumor frequently may be the first sign of the development of the cyst; in other cases digestive disturbances may occur and then subside, only to return later with greater intensity—colics, vomiting and constipation—the attacks recurring at irregular intervals. A number of the patients were treated for dysentery, liver trouble, etc., years passing before the cyst was diagnosed and the patient cured at once by its removal. Pain was not experienced in 5 of the cases on record, but in 26 others it was severe, paroxysmal or continuous, indicating compression of organs or nerves, with resulting functional disturbances. The genital functions are frequently disturbed, menstruation becoming painful and irregular or being suppressed altogether. The cyst is generally median and in the region of the umbilicus and extremely movable. A spontaneous cure is recorded only in 2 of the total 32 cases he reviews.

49. **Treatment of Popliteal Aneurism.**—Quénu and Muret analyze the recent literature on the subject of surgical treatment of aneurism, comparing the various technics. Their conclusion is that for the majority of cases Matas' endoaneurismorrhaphy, described in The Journal, Sept. 29, 1906, p. 990, and Nov. 14, 1908, p. 1667, is the superior technic as this permits individualization of measures to suit the special conditions exposed when the vessel is opened. Goyanes' method may possibly have a future, they say; this makes a double anastomosis between the artery and vein, possibly excising or isolating the aneurism pocket.

51 *Formaldehyd Sterilization by Slow Combustion of Straw. (Désinfection en surface de certains locaux par la combustion incomplète de la paille.) A. Trillat.

51. **Formaldehyd Sterilization by Slow Combustion of Straw.**—Trillat explains the mechanism by which the aldehyd and polyphenol substances generated in slowly burning straw result from oxidation of the gases of combustion acting on the hot straw charcoal. In his experiments he found polymerized formic aldehyd in the proportion of 0.2 to 2 gm. per kilogram of the straw by weight. The polyphenols generated

at the same time add their disinfecting action: other important factors in the sterilization are the high temperature and the presence of pyroligneous acid. All antiseptics, and especially formaldehyd, have a more powerful action in an acid atmosphere and at higher temperatures. He advises plugging all crevices and piling the straw in layers of dry straw alternating with damp layers. The temperature of the enclosure should be 87 F. at least, and it is best to set several of the straw fires at work at once. In a cellar of 140 cubic meters, 18 kilograms of straw were burnt thus and objects contaminated with diphtheria and colon bacilli were rendered sterile in less than two days and all but 1 in 12 tests with typhoid bacilli and 5 in 12 tests with anthrax spores. This method of sterilization is only adapted for cellars, sewers, tunnels, stables, etc., as the walls are slightly smoked. The sterilization is only superficial.

Archiv für Verdauungs-Krankheiten, Berlin

February, XVI, No. 1, pp. 1-120

52 *Dilatation of the Esophagus. (Erweiterungen der Speiseröhre.) F. Umber.
53 *Importance for Diagnosis and Treatment of Schmidt's Test Diet in Intestinal Disease. (Wert der Schmidtschen Probekost bei Darmkrankheiten.) W. Robin.
54 *Recurrences after Operative Removal of Gall-Stones. (Ueber Rezidive nach operativer Behandlung von Gallensteinen.) S. Mintz.
55 *Gall-Stone Colic with Movable Gall-Bladder. (Neue Form von Gallensteinkolik bei beweglicher Gallenblase.) M. Buch.
56 *Local Eosinophilia and Intestinal Disease Accompanied with Eosinophilia. J. Komarowsky.

52. **Dilatation of the Esophagus.**—Umber reports a typical example of the "pulsion" diverticulum and of diffuse dilatation in the upper and lower part of the esophagus. In the first case the father of the patient had a similar affection, confirming the congenital tendency to special weakness of the muscle at the junction of the pharynx and esophagus. The physiologic internal pressure in the esophagus, to propel the food along, causes protrusion of this part of the wall, with formation of a diverticulum in time. As it is due to the propulsion of the food, it is called a "pulsion" diverticulum. The disturbance in swallowing, regurgitation, tumor in the neck and murmur suggested the diagnosis, which was confirmed by Roentgen-ray examination. The case of diffuse dilatation illustrates, he states, that high degrees of ectasia may develop without primary stenosis, exclusively on the basis of a primary congenital atony of the wall of the esophagus.

53. **The Schmidt Test Diet for Diagnosis and Treatment of Intestinal Disturbances.**—Robin has been systematically applying Schmidt's diet in 42 cases during the last three years, and is convinced of its great importance for proper differentiation and treatment of chronic bowel trouble. He gives the details of six cases, each a type of various conditions, in which this method of testing the functioning gave useful information, leading to a complete cure of conditions which had previously resisted all kinds of treatment applied haphazard. Examination of the stools during the test ration supplied the clue to the disturbances, revealing the special elements in the food which the patient was unable to digest properly.

54. **Recurrence After Operative Treatment of Gall-Stones.**—Mintz reports two cases of unmistakable recurrence of gall-stones after removal of the gall-bladder and drainage of the ducts. He is convinced that surgical intervention should be limited to cases of gall-stones with suppurative inflammation of the gall-bladder and chronic obstruction of the common bile duct, and, under certain conditions, chronic serous cholecystitis.

55. **Gall-Stone Colic with Movable Gall-Bladder.**—Buch gives an illustrated description of a case in which two large stones filled the gall-bladder. The latter was movable and its movements were evidently responsible for changes in the position of the stones, their movements causing the severe colic.

56. **Local Eosinophilia and Eosinophilia with Intestinal Diseases.**—Komarowsky reviews recent research in this line, of which a large amount has been done in Russia, and reports two cases of amebic enteritis with local eosinophilia without general eosinophilia and without Charcot-Leyden crystals. In both cases the stools contained a little blood. In two other cases there was local eosinophilia accompanying severe colitis, the eosinophilic cells forming the main mass of the leucocytes in the intestinal mucopurulent secretion, but there were no Charcot-Leyden crystals. His conclusions are that the hemolytic processes and phagocytosis occurring in the intestine are sufficient to explain the intestinal eosinophilia. This throws light on the eosinophilia observed with parasitic affections. One of his cases may be regarded as belonging to the type of exudative eosinophilic proctitis, no actual ulcers developing.

58. **Antidiabetic Foods.**—Magnus-Levy has examined nearly four dozen different foods on the market advertised for diabetics, and he found that they frequently failed to conform to the alleged standard. He urges manufacturers to use greater care in insuring uniformity in their products. He advocates two kinds of bread as enough for all practical purposes: one with a maximal content of 30 per cent. starch, the other with 5 or 10 per cent. starch. Other ingredients should be proportionately 16—20 per cent. albumin; 12—14 per cent. fat; 2 or 3 per cent. ash (salt), with 1 to 3 per cent. cellulose and 30 per cent. starch.

59. **Syphilitic Jaundice.**—Bruns found leucin and tyrosin in the urine in a case of mild jaundice in the early phase of syphilis. This finding is characteristic of acute yellow atrophy of the liver, but the mild course of the jaundice in this case shows that a parenchymatous inflammation of the liver may occur and retrogress without leaving serious traces. It is possible, however, that the liver may prove less resistant thereafter. All Bruns' patients with syphilitic jaundice in the last two years have been examined for tyrosin and leucin, but this, with two infants with inherited syphilis, were the only ones giving a positive response.

62. **Acute Rheumatic Polyserositis.**—Mosler has encountered 15 cases during the last 18 months in which the serous membranes showed signs of inflammation in the course of an acute articular rheumatism, or the polyserositis developed with only slight involvement of the joints. In both forms the disease has a sudden onset, the pleurisy and pericarditis developing together and abruptly. The violent dyspnea and other symptoms observed are evidently the work of the pericarditis without effusion; the pleura generally has a bilateral effusion. In some of the cases the pleuritis and pericarditis are complicated with endocarditis developing with the others or not long after them. The pleurisy in these cases does not require tapping as the effusion generally subsides spontaneously and without production of linear adhesions, as also occurs with the pericarditis, but the inevitable myocarditis takes a longer time for its retrogression and usually entails mitral insufficiency. The prognosis is the more favorable the

longer the interval since puberty, the heart of the young feeling the deleterious influence of the inflammation more intensely. His patients were between 14 and 49; the 4 left with valvular incompetency were 14, 15, 20 and 34 years old. One patient, a boy of 16, died.

63. **Prognosis of Cancer.**—Brieger cites an example to show the valuable information to be derived from estimation of the antitryptic power of the blood serum in regard to the prognosis of cancer. In the case described it was 1 to 7 at first but dropped to the normal proportion, 1 to 4, after removal of the cancer. A few months later, however, the proportion rose to 1 to 8, testifying to the development of metastases, which soon became manifest on palpation. It was thus possible to detect the metastases by the antitryptic ferment test before any other signs revealed their presence. The principles and technic of the antitryptic test were given in The Journal, July 4, 1908, page 83.

67. **Action of Radium on Man.**—Loewenthal concludes from his observation and experimental research that the biologic action of radium and radium emanations is evidenced in an activation of the ferments in the body; he was unable to discover anything suggesting an antitoxic or similar influence.

74. **Treatment of Nevus with Mercury Quartz Lamp and Radium.**—Kromayer reports 40 cases treated with one or both of these measures, the results showing that small, red arterial nevi respond favorably to radium treatment as its action is deeper than that of the lamp. But the latter is effectual for extensive reddish and purple nevi if they are superficial and are mainly the result of dilatation of the capillaries with slight involvement of the arteries. Moderately large, mixed nevi, the class which forms the majority of cases, require the combination of the light and radium treatment. He has never obtained any durable benefit from Roentgen-ray treatment, the difference between the radium and Roentgen rays being mainly in their various action on the vessels. The complete cures in a large number of his cases indicate that the quartz lamp and radium combination is a decided progress. Only a few of the 40 patients were *not* benefited by the treatment. He never makes more than 4 or 5 exposures with the mercury lamp nor more than 2 or 3 with the radium, *never* over an hour in length.

76. **Angina Abdominis.**—Kreuzfuchs describes the symptoms of abdominal *arteriosclerosis* as paroxysmal pains in the stomach region or elsewhere in the abdomen, especially around the umbilicus and tympany. The syndrome may be that of arteriosclerotic epigastralgia or true angina abdominis. In differentiation it is important that the attacks occur independent of the intake of food but are elicited by the factors which experience has shown induce symptoms in heart and vascular affections. Another point is that the abdominal angina is most liable to develop when the patient reclines. It is more common in men than in women, and most of the patients are over 40 or 50 years old. The *diagnosis* is confirmed by discovery of some other arteriosclerotic disturbance, or by the success of measures directed against arteriosclerosis. Intestinal hemorrhage and constipation are frequently observed; 4 of his 6 patients were great smokers. Ortner and Basch were able to induce spasmodic contraction of the intestines in animals by injection of nicotin. The prognosis of severe intestinal dyspragia is grave as it usually is the last link in a long arteriosclerotic chain. In one case the patient seemed to be much improved after a long series of cardiac symptoms when an attack of angina abdominis came on and death soon followed. The aim in treatment is to reduce the spasmodic contraction in the intestinal vessels; moist heat, hot drinks and physical measures are useful, but the sovereign measure is morphin. As there is danger of collapse as the spasm is relieved, he combines camphor with the morphin; there is little danger of morphin addiction as the prognosis of the affection is so grave in itself. The patients must guard against effort, "catching cold," and dietetic errors, and the bowels must be kept open, but laxatives and an anticonstipation diet must be given with caution as they are liable to bring on an attack; enemas must be the main reliance for this. The heart must be kept working well and physical measures are useful here, rather than haphazard digitalis medication. His experience, he states, confirms the benefits from cautious abdominal massage in regulating the conditions in the circulation in the intestines.

84. **Experimental Production of Goiter.**— This communication from Wilms' surgical service at Basel relates extensive experimental research which has confirmed the assumption that the drinking water in certain geological formations contains the substance which produces both goiter and cretinism. The experiments were made with dogs, rats, guinea-pigs and monkeys, and enlargement of the thyroid followed ingestion of water from certain springs in regions where goiter is endemic; goiter also developed in the animals when the residuum after filtration of such water was added to water from springs in other regions free from goiter. The fact that the thyroid is the one gland affected by this element in the water confirms the assumption that the element in question here is a poison rather than a microorganism. The special geological formations involved seem to be determined by this research.

86. **Operative Treatment of Nephrolithiasis.**—Makkas concludes from the experiences at Garrè's surgical service at Bonn that pyelotomy is the preferable operation in case of kidney stones, and that the wound heals without a fistula if certain precautions are taken, such as he enumerates.

88. **Chromocystoscopy.**—The indigocarmin test of kidney functioning was described in The Journal, Jan. 2, 1904, page 69. Its extensive use in Bier's surgical service at Berlin is here reviewed, the clinical history, operative findings and ultimate outcome in fifty cases being presented in detail. The

final conclusions are that the test is an essential and valuable acquisition for obtaining information in regard to the actual functional condition of the kidney in certain circumstances. It is the more valuable on account of the simplicity of the technic.

89. **Roentgen-Ray Treatment of Surgical Tuberculosis.**—This is the detailed report of the work in this line done by Wilms and under his direction, mentioned recently in The Journal, page 1014, abstract 74.

93. **Direct Serum Treatment of Suppurative Processes.**—Gergö describes the experiences in Dollinger's surgical service at Budapest with the injection of serum—Müller's antiferment treatment—in 160 cases. The principles and technic were mentioned in The Journal, Aug. 28, 1909, page 751. This physiologic treatment is said to have proved satisfactory in nearly every instance, and Gergö regards the method as destined to a brilliant future when further perfected. Its special field is for abscesses unless they are unusually extensive and deep or the patient much debilitated, in which case incision is necessary. Otherwise all that is necessary is to paint the outside with iodin, aspirate the contents of the abscess with a puncture needle and then inject pure serum, thus rinsing out the cavity, after which serum to an amount representing one-third or one-half the amount of abscess contents withdrawn is injected, and a scrap of gauze is laid over the puncture hole and held in place with a strip of plaster. An abscess containing from 1 to 5 c.c. of pus heals in 3 days; larger ones, containing from 20 to 50 c.c. of pus heal in about 11 days. The absence of a scar is one of the great advantages of the method, and the functional result is always better, as conditions are more physiologic. He has never encountered any signs of anaphylaxis and the abscess never progressed except in a single instance, in a very debilitated patient. The benefit is *apparent only when there is decided abscess* formation.

Medizinische Klinik, Berlin

101 Syphilis in Rabbits. (Neue Untersuchungen über die Syphilis des Kaninchens.) M. Truffi.

96. **Scleroma.**—Gerber regards scleroma as an infectious granuloma, with the connective-tissue *shriveling following* directly on the granuloma without an intervening stage of ulceration. He gives a number of illustrations of the different types which it may assume in the upper air passages, mouth and nose, urging a combination of surgical and physical measures, Roentgen-ray and radium exposures, etc. The absence of ulceration helps to differentiate the scleroma from syphilis. It is most liable to be confounded with tuberculosis but the tissues are harder and the aspect is not that of a typical tuberculous process. No means are known, he declares, by which scleroma can be arrested, but repeated palliative measures may allow years of freedom from discomfort.

97. **Psychoneuroses.**—Stekel enumerates a number of typical cases of psychoneurotic obsessions which are liable to drive the victims to despair but which can be cured, he says, by study of the individual conditions, the trouble being always some conflict in the psychoemotional sphere, logical, but subconscious. By winning the patient's confidence, the physician can trace out the underlying bases for the obsession, and, once discovered, the cure is soon complete. He agrees with Freud that the underlying basis is of sexual origin, and even goes so far as to state that in this category should be included all the cases now labeled neurasthenia. Nothing more rejoices the soul of the physician, he declares, than to be able by appropriate treatment to restore to normal life and the joy of existence the victims of these "anguish neuroses." He suggests the term "parapathy" for all that we have hitherto called neuroses and neurasthenia, remarking that a new science and a new conception of ideas demand a new terminology. The nerves, as such, have nothing to do with neuroses. The constitution may pave the way for the development of neuroses, but certain conditions in the environment are the main factor.

99. **Differential Diagnosis of Hysteria.**—Meyer insists that it is impossible to exclude all organic affections, as the textbooks advise, in striving to differentiate hysteria. Attention should be directed to the features which distinguish the hysterical manifestations from those of like nature of organic origin. In recurring disturbances, a strict periodicity speaks strongly in favor of hysteria, as also a strictly regular rhythm. The influencing of the symptoms by emotions should not be regarded as a criterion of hysteria, as many organic affections are powerfully modified by emotions. The effect of medical measures is an important aid in differentiation but of still greater import is the absence of the ordinary influence of drugs. When a pain is not materially modified by antipyretics or morphin, its hysterical origin is more than probable. He urges the necessity for refraining from physical examination of patients suspected of hysteria; the stigmata are frequently suggested to the patient by the physician's *examination. It is impossible to examine thoroughly all the* organs of any living human being and unnecessary inspection and manipulations should be avoided, especially on suspicion of hysteria.

102. **Congestive Hyperemia in Treatment of Carbuncle on the Face.**—Keppler reports further experiences with active hyperemia *applied to lesions on the head, his further experi*ence confirming the good results obtained four years ago, as mentioned in The Journal at the time, Feb. 10, 1906, p. 473, where his technic was also described. He has not modified the technic since, but declares that the benefit of constriction applied to the neck in treatment of lesions above makes necessary a revision of all previous therapeutic views in this field. Instead of mutilating surgical measures, all that is necessary is to remove the cap of the pustule, leaving the necrotic plugs until unmistakably loosened. Great care is taken not to injure the tissues, carefully avoiding squeezing out the pus. The carbuncle rapidly softens under the influence of the elastic band applied to the neck, but the most remarkable effect of the latter is the prompt subsidence of pain. The constricting band is worn 20 or 22 of the 24 hours, and even after the symptoms have subsided he keeps up the constriction for a few hours every day. The dread that some physicians have of applying constriction to the neck he regards as unfounded; extremely mild constriction answers the desired purpose, the vessels in the neck being so large in comparison with the muscles, that the conditions thus differ materially from conditions in the limbs. He retracts nothing from his first commendation of the method, but is even more emphatic. He applies the constricting band also for carbuncles on the back of the neck when they are located high enough to permit. The results were good in his 4 cases of the kind.

105. **Simple Test for Uric Acid in the Blood.**—Roethlisberger describes a method of determining the proportion of uric acid in the blood, which he states is extremely sensitive,

simple and reliable. It is based on the fact that uric acid reduces a solution of silver carbonate. To facilitate the test he uses a reagent paper, a silver carbonate paper, on which a drop of a 15 per cent. solution of sodium carbonate is placed and as soon as this has all been soaked up by the paper, a single drop of blood serum is placed in the center of the moist spot on the silver paper. After two minutes the paper is rinsed and then placed for five minutes in a solution of 1 part pure ammonia in 2 or 3 parts distilled water. The paper is then rinsed again, when it can be examined. After lying in the water-bath for a few hours, the paper can be dried and kept indefinitely. The only drawback to the test is that the whole procedure must be done in a dark room with red light or an electric 10-candle light at a yard distance, as the sensitized paper must be kept from contact with daylight. He gives illustrations of the reaction to show the scale. There is no trace of the spot in the absence of uric acid, but a faint spot is seen with 0.04 per thousand uric acid; the spot is more distinct with 0.08 per thousand, and quite a blotch with 0.12 per thousand. Only a few drops of blood from the finger tip are necessary; the serum separates on standing without centrifuging.

107. **Habitual Torsion of the Elongated Cecum.**—Klose distinguishes between the disturbances with an abnormally long movable cecum with chronic inflammatory conditions responsible for the stretching of the connective tissue, and that due to anomalies in development. This latter variety is much more frequent but has received little attention, and yet its non-recognition may lead to serious and possibly fatal trouble. The victim usually applies to one physician after the other, and finally comes to be regarded as a chronic neurasthenic or hysterical individual. An abnormally long cecum causes no disturbance in the majority of cases, but in others there are severe symptoms which Wilms ascribes to the length of the cecum but which Klose explains as a periodical or a constant relative or absolute torsion. These cases probably include all those in which the disturbances persist after appendicectomy for supposed chronic appendicitis. Klose has examined the records of operations for chronic appendicitis in which the report allows a suspicion of a movable cecum as a possible factor, and found many instances of persistence of the severe attacks of pain after the operation, just as before. In fully 25 per cent. of all cases of alleged chronic appendicitis the trouble in reality, he reiterates, is habitual torsion of an abnormally long, movable cecum. In the milder cases, not yet complicated by secondary adhesions, a tumor-like resistance can be felt, during the attack, in the region of the cecum, which can be pushed across the median line; the tumor may then disappear under pressure. Gurgling and rumbling noises can be heard on auscultation. This tumefaction, in connection with the lack of fever during the attack of pain, is the most important feature for differentiation. The severe cases are generally diagnosed as some form of stenosis, but Roentgen-ray examination has permitted the correct diagnosis in all his numerous cases in the last year. The main features of the attack are the colics with distention of the cecum, increased peristalsis, sounds on palpation, obstipation followed by diarrhea, and the pain from the tugging and distention with partial stiffness of the intestine, blood and mucus in the stool, with fermentation of carbohydrates, or ileus. He found the condition in children in about 13 per cent. of his total material and calls the attention of pediatrists to this fact, reporting two typical cases. The children are those suffering from constitutional or infectious injuries, or, as only children, held aloof from the healthy and strengthening exercises of normal childhood. Treatment should be intraperitoneal fixation of the cecum, fastening it to the peritoneum of the iliac fossa and the posterior lateral abdominal wall with silk button sutures of the serous surface. He regards Wilms' plastic operation as unnecessary. Wilms forms a pocket in which the cecum is placed by loosening a triangular portion of the peritoneum from the crest of the ilium. Simple intraperitoneal cecopexy, which Klose prefers, has the advantages of putting an end to the further torsion while preventing infection of the suture. In all operations on the appendix, he declares, an abnormally movable cecum should be fastened to hold it in place. The article is illustrated.

121 Mercury Oxycyanid in Syphilis. (Zur Injektionsbehandlung der Syphilis.) Jessner.

115. **Glycerin in Treatment of Helminthiasis.**—Preti reports 3 cases in which the ordinary vermifuges entirely failed to relieve the patients of the *Anguillula intestinalis.* He finally succeeded in expelling the parasites by giving glycerin freely. The patients took 25 gm. of pure glycerin and the same amount in capsules, with 30 gm. by the rectum two hours later. Two days later the same procedure was repeated, and for the first time in years the stools were free from the larvæ. In one case, complicated with uncinariasis, the latter was cured by the ordinary treatment with male fern but the anguillula did not seem to be affected by it.

119. **Extension Dressings in Treatment of Fractures.**—Bockenheimer's article is accompanied by twelve illustrations showing the various types of dressings arranged to induce extension of the fractured limb while leaving the joints free. In the simpler cases the extension can be applied in the home by the family physician. Owing to the constantly increasing use of machinery, the greater devotion to sports, roller skating, automobiling, etc., fractures are becoming more common while better functional results are demanded than formerly were acceptable. For this, extension and early massage are almost indispensable, and the combination of extension with the dressings is proving very useful. In fracture of the upper arm, for instance, he applies a lengthwise strip of adhesive plaster on each side of the arm, extending below the elbow, the lower ends fastened each with an elastic band to a wooden crosspiece several inches below the elbow, which in turn is fastened to two wooden splints extending from the shoulder to several inches below the elbow, the hand resting in a sling. The upper arm is thus stretched constantly but with elastic force. Ideal retention without the slightest impairment of function is possible only with extension, he declares. He also insists that the patient must refrain from bearing weight on the leg in case of fracture of the thigh for at least 12 weeks and for 7 weeks in case of fracture below the knee. He also emphasizes the importance of having the patient wear a flat-foot insole for a year after any fracture of the leg below the upper third of the femur.

126 Experimental Research on Drainage. S. Boxer and J. Novak.
127 Dislocation of Ulnar Nerve. R. Porges and M. Jerusalem.

123-124. **Study of the Blood of Menstruating Women.**—The investigations of Cristea and Denk seem to have demonstrated that the blood undergoes no change in respect to its coagulating properties during menstruation, but that the uterine mucosa has the property of holding back the fibrin ferment. This renders the blood passing through this mucosa incapable of normal coagulation. Pölzl gives curves to show the regular increase in the numbers of red corpuscles a few days before the menses, the numbers diminishing again just before the onset of the menstrual hemorrhage. This may have something to do with the functioning of the ovaries, and the numbers of reds at this time may thus serve as an index of ovarian functioning. In examining the blood of menstruating women, the date of the examination, in connection with the menstrual period, should be borne in mind. It is possible that with the increased functioning of the ovaries just preceding menstruation, other organs, including the bone marrow, may feel a stimulus to more active functioning.

125. **Blood Findings with Chronic Enlargement of the Spleen.**—Hess gives the details of a number of cases of various affections of the spleen as observed at von Noorden's clinic at Vienna. He found unusually small numbers of leucocytes with enlargement of the spleen accompanying a primary neoplasm in the spleen, acquired syphilis, chlorosis and severe anemia, as also in Banti's disease. On the other hand, he says, the proportion of leucocytes was constantly normal in inherited syphilis, chronic malaria, chronic congestion of the spleen, splenic cirrhosis, polycythemia, wandering spleen, amyloid degeneration, tuberculosis of the spleen and metastatic tumors.

128 *Tannin Sterilization of the Skin. (Zur Hautdesinfektionsfrage.) A. Zabludowski.
129 *Hemostasis in Trephining. (Zur Technik der Blutstillung bei Trepanationen des Schädels.) Vorschütz.

128. **Tannin for Surgical Sterilization.**—Zabludowski comments on the yellow discoloration from the benzin-iodin method of disinfecting the hands and field of operation, which is its great drawback. The hands are liable to be irritated, besides. The acetone method or iodin alone is only for the field of operation and not for the hands. He proposes tannin for effectual sterilization, commending its vigorous and permanent action, while it is not irritating and water does not impair the effect. He uses the tannin in a 5 per cent. alcohol solution, and reports faultless results when the hands and field of operation were cleansed for two minutes with gauze dipped in this solution. In 32 major operations in which this technic was used, bacteriologic tests of the hands during and even 40 minutes after the operation showed that they were as clean as at first.

129. **Hemostasis in Trephining.**—The needle is passed through the tissues between the periosteum and the bone at the point that is to be the base of the flap; an attached contrivance fastens the tissues down to the needle, like a safety-pin clamp. This shuts off the blood supply to the flap. As the incision is carried further the soft parts are seized with special broad clamps, the row of clamps entirely encircling the incision. As the handles lie away from the wound they do not interfere with the operation. The article is illustrated.

February 15, No. 20, pp. 209-216

136 Unreliability of Skin Reaction in Typhoid. (Ricerche sulla cutireazione nella febbre tifoide.) P. Ciuffini.

132. **Primary Abscess in the Spleen.**—Belloni and Moschini report the favorable result of prompt operative intervention in a case of primary abscess in the spleen. The first symptoms were low fever, headache and pain under the seventh rib, radiating to the shoulder. In the course of two months increasing fever and chills compelled intervention and rapid recovery followed resection of two ribs to permit evacuation of pus from between the lobes of the lung, after evacuation of the pus in the spleen. In the other case, no operation was attempted, although subphrenic suppuration was suspected; autopsy revealed merely a small primary abscess in the spleen with abundant pleural effusion. Both patients were young men.

133. **Iodoform-Glycerin in Surgical Lesions.**—Vandini reports satisfactory results in treatment of all kinds of acute and chronic abscesses, tuberculous peritonitis, phlegmons, mastitis, and various medical affections with effusion. Extensive experience, he states, has confirmed the advantages of this simple treatment which renders mutilating operations unnecessary as a rule. He uses a mixture of 10 parts iodoform in 100 parts glycerin, which he injects through a wide puncture needle after he has withdrawn some or all of the contents of the abscess or other process. He has never found it necessary to make more than three or four injections; one is generally sufficient, as he shows by a number of examples reported. The method has also proved effective in his hands in inflammatory processes in the knee, in acute peritonitis, polyserositis, and in pleurisy with effusion.

135. **Impossibility of Freeing the Body from Malarial Parasites.**—Mircoli declares that the recurrences of malarial symptoms after 5 or 10, or even 20 years, in connection with other facts that he has observed, have convinced him that the present drug treatment of malaria is unable to free the system completely of the malarial parasites. They linger in some form and recurrences after 20 years are not very rare, nor even after 40. There are absolutely no data, he says, on which to base the assertion that the malaria germs can be totally eradicated. Like syphilis, trypanosomiasis and kala azar, malaria, according to Mircoli, is "etiogenically incurable." According to the place and the individual, prophylaxis against eventual recurrence should be by systematic arsenic medication, and this applies as well to non-malarial as to malarial regions. Among the facts cited to sustain these assertions is the case of a youth with malarial infantilism whose much enlarged spleen was removed. Not a trace of malarial parasites could be detected in the spleen, but the next day they were found in the blood. They must have been present in the spleen in some amorphous, invisible form. The possibility of the existence of the parasites in some form which escapes present means of investigation has been demonstrated by Marchiafava in cases of primary malarial infection in which the blood marrow failed to show the least trace of the parasites. Enlargement of the spleen indicates inevitably active malaria, Mircoli declares. The absence of demonstrable protozoa, however, is no evidence against their existence in some germinal stage or against their habitual, although possibly silent, revivification.

146 *Diagnosis of Syphilis by Staining Reaction. (La cromoreazione di Schürmann per la diagnosi della sifilide.) V. Chirivino.

146. **Staining Reaction in Diagnosis of Syphilis.**—*Chirivino* relates the results of application of Schürmann's staining technic in 80 persons with unmistakable syphilis and in 17 free from a history of syphilitic infection. The reaction was positive in 64 of the 80 syphilitics, including 6 with very old syphilis. Of the 17 free from a history of syphilis only one presented a positive reaction, and this patient had an infectious ulcerative process. The Wassermann reaction gave parallel findings with the staining test with a single exception. In one case, a medical student presented a lesion on the genitals which had the aspect of a primary syphilitic sore, but no spirochetes could be found in it and the stain reaction was negative; the further course of the case confirmed the negative diagnosis. Chirivino declares that the staining test is far simpler than the search for spirochetes and the Wassermann reaction, and therefore he commends it to the general practitioner as a simple and easy means of throwing light on the case in question, confident that it will prove reliable in at least 80 per cent. of the cases. The technic for the staining reaction was given in The Journal, May 15, 1909, page 1629. Chirivino summarizes it as follows: One drop of perhydrol is added to 0.1 c.c. of the serum mixed with 3 or 4 c.c. of physiologic salt solution. When this is all well mixed he adds 0.5 c.c. of the freshly made special reagent (0.5 parts phenol with 0.62 parts of a 5 per cent. solution of ferric chlorid and 34.5 parts of distilled water). With normal serum the fluid turns greenish and then bluish, but remains constantly clear. If the serum is from a syphilitic, the fluid turns a dark, opaque brown. The addition of another drop of perhydrol sometimes turns a dubious into a pronounced positive reaction. The reaction occurs within a few minutes; after 10 or 15 minutes even with a negative reaction the fluid assumes a brownish tint although still constantly transparent.

152 *Tumors in the Cerebello-Pontine Recess. (Om acusticustumorer.) F. Henschen.

151. **Laws Regulating Digestion and Absorption of Food.**—Arrhenius states that some of the investigators at Pawlow's laboratory, including London, appealed to him to study the results of their research on dogs with a Pawlow fistula to ascertain if there were not some special laws governing the phenomena observed. He gives the details of his methods of research and states that the data presented suggest a suspicion of certain simple mathematical laws to which all the phenomena observed seem to conform as he describes in detail, giving the formulas to embrace the factors of amount of ingesta, time of digestion, proportion absorbed, amount of gastric secretion, etc.

152. **Tumors in the Auditory Nerve.**—This comprehensive article is a sequel to one on the same subject published in the *Hygiea Festband* in 1908. Henschen here gives 11 tables, each with 35 columns, citing the minutest details in regard to the clinical data and autopsy findings in 140 cases of tumors found in the recess between the cerebellum, medulla and pons. The list includes 11 cases in which these tumors were merely one manifestation of a general neurofibromatosis. He gives a number of points useful for differentiation, calling attention especially to the sequence in which symptoms develop. Headache is generally the initial symptom, but disturbances in hearing, vertigo or difficulty in walking may be the first symptoms, less often, disturbances in vision occur. Examination of the ear is of great importance for determining the side on which the lesion is located. In 5 of the 25 cases in which the tumor was removed the results have been excellent. Even an early palliative operation has a beneficial action. It is remarkable that no well-authenticated case of a solitary tumor originating in any other of the cranial nerves except the auditory nerve is on record; the explanation for this, he thinks, is probably in the embryonal development. The auditory nerve tumors originate in the connective tissue in the fundus of the internal auditory meatus in or around the vestibular division of the auditory nerve. As they grow they extend into the space between cerebellum and pons and develop as true intracranial tumors. But this recess may also be the seat of tumors originating in other regions near by. The tumors are generally more or less spherical and easily shelled out, of a fibroid nature, and more or less benign growths.

THE TUBERCULOSIS MOVEMENT

RECENT OBSERVATIONS WITH REFERENCE TO CERTAIN CLINICAL ASPECTS *

S. G. BONNEY, M.D.

DENVER

Tuberculosis, of all communicable diseases, has in the past decade enlisted the best efforts of medical workers in all civilized countries. There have resulted laborious scientific research, detailed clinical study, effective organization for its control, valuable investigation of a sociologic and economic nature, and an almost inexhaustible supply of literature. In view of the innumerable factors inherent in a problem of such magnitude, it is impossible here to attempt a consideration of other than a single phase to which my attention of late has been directed.

Unusual opportunities for comparative observation sometimes affording approximate accuracy of conclusions are given to physicians residing in favorable climates. From an experience of eighteen years in Colorado, I venture to allude to certain recent tendencies of the profession with reference to a disease in which unfortunate results are often quite conspicuous.

It is evident that a most frequent disease concerning which serious errors of diagnosis and treatment seem almost impossible, continues, nevertheless, to present grievous difficulties in its early recognition and rational management. That this should be true in view of the active educational propaganda appears remarkable. A scrutiny of conditions, however, discloses the fact that to some extent, paradoxic as it may seem, the campaign against tuberculosis has been indirectly responsible.

CONSERVATISM VERSUS MEDICAL FADS

Following the greater impetus to the tuberculosis movement and the added incentives for clinical proficiency, there has apparently developed a growing inclination toward refinements of diagnosis and conventionalities of treatment. In the midst of the present enthusiasm regarding the new methods of diagnosis and the advantages of the sanatorium is there not manifested a disposition to exalt the practical utility of several diagnostic and therapeutic agencies to a point far above their true value? A just and well-proportioned estimate of the relative importance attaching to some clinical features may not always be entertained if judicious conservatism is opposed by prevailing medical fads. In the same way efforts to develop a comprehensive and effective system of prevention must fail of the fullest success unless cognizance is taken not only of fundamentally important factors, but also of all possible negative phases. To determine their legitimate scope it is as essential to avoid an exaggeration of their advantages as to admit their value within proper limitations. Thus, while institutions for the care of tuberculous invalids are demanded to satisfy individual and social requirements in the cause of prophylaxis, their overwhelming *value in therapeutic management and their unvarying applicability to all classes and conditions have not so far* been subject to demonstrable proof. Although a vitally important factor in the general problem of tuberculosis, the practical usefulness of the sanatorium consists largely in its coordinated relation to other valuable measures of prevention and management.

It is well to inquire to what extent, if any, as a result of the increasing interest in tuberculosis, pulmonary invalids are profiting by earlier diagnosis and more prompt recourse to favorable climates. My recent experience has been materially different in some respects from that of previous years.

EARLY DIAGNOSIS

In the past a serious reflection has been the delay in recognizing the disease, occasioned in many instances by an incomplete review of the history, a superficial inquiry regarding the subjective symptoms, an inadequate and hasty examination, and failure to examine the sputum. Errors of diagnosis were not then referable to the absence of *x*-ray equipment, lack of familiarity with laboratory technic, the impracticability of utilizing guinea-pigs for animal experimentation, or of employing tuberculin in subcutaneous injection. In the majority of instances the simpler means of diagnosis were sufficient to have warranted a much earlier recognition of the disease. Many patients were sent to health resorts only when the disease had become most active and extensive, months after a diagnosis of malaria, bronchitis, typhoid fever, influenza or catarrhal laryngitis had been made. I have previously reported that in a series of 2,300 patients the average period of delay following the recognition of the disease before arrival in Colorado was eighteen months.

SOME CLINICAL FINDINGS

Among the last 313 invalids coming under observation since the compilation of other statistics, the physical examination of the chest was entirely negative as regards tuberculosis in 90 instances, or more than one-quarter of the total number. Bacilli were not found in the sputum in 87 cases. They were occasionally recognized, however, in the absence of physical signs of tuberculous involvement, and *vice versa*. Of the doubtful cases without either physical or bacteriologic evidence of tuberculosis a tuberculin test was negative in 41; 87 presented a vague, ill-defined history of indisposition with suspicious subjective manifestations during from two weeks to four months. Notwithstanding the short duration of these cases, it is of interest to note that the average period of delay for the entire 313 patients is sixteen and one-quarter months, which is nearly as large as that previously reported. This is explained by the fact that, despite the unusually large number of doubtful cases, 125 patients, or about two-fifths of the entire group, were found on arrival to be in advanced stages. That the condition was truly desperate in so large a number is shown by the death of 62, although the period of observation has been comparatively short. Sixteen individuals were sent home as utterly hopeless cases. It thus appears that out of 313 new arrivals 90 are classed as doubtful and 125 as very advanced, leaving a relatively small number exhibiting definite infection of incipient or moderate degree.

---

* Read before the Chicago Medical Society, Nov. 3, 1909.

On the basis of the physical examination, bacteriologic findings and tuberculin test, 41 patients are adjudged non-tuberculous. Among a somewhat larger number the previous diagnosis was justly subject to suspicion, there being no substantial confirmation of an active tuberculous infection, although in some instances a positive cutaneous reaction had been obtained. The condition was apparently chronic bronchitis with or without emphysema in 14 instances, non-tuberculous bronchiectasis in 4, pulmonary abscess in 2, pleural effusion in 4, empyema in 1, pericarditis in 1, probably pulmonary syphilis in 2, tuberculosis of the peritoneum in 4, tuberculosis of the intestine without pulmonary infection in 3. Of the remaining cases without physical or bacteriologic evidences of tuberculous pulmonary involvement, the symptoms were largely those of anemia, neurasthenia and recent bronchitis without material loss of weight or elevation of temperature.

Among the clearly tuberculous cases, nephritic complications with albuminuria were present in 25 instances and incurable infection of the larynx in 15. Intestinal tuberculosis was demonstrable in 7; 29 had been treated for somewhat prolonged periods for supposed typhoid fever or malaria, while 19 exhibited a distinct pneumonic onset, and in 12 of these the disease pursued the characteristic course of acute pneumonic phthisis. A considerable number reported that the condition had been regarded as catarrhal or tuberculous laryngitis, local applications having been applied during a period of many months, although no visual appearance of laryngeal involvement was subsequently exhibited. Several cases of many years' standing conformed strictly to the fibroid type. Patients with marked shortness of breath from extensive emphysema and beginning cardiac dilatation were occasionally observed.

CORRECT INTERPRETATION OF PHYSICAL SIGNS

It was, perhaps, to have been expected from previous observations that many cases would represent either advanced stages of the disease or important complications. That so large a proportion exhibited doubtful or negative evidences of tuberculosis has been a source of considerable surprise. Had my experience in this respect been radically different from that of local confrères, I might be forced to acknowledge a personal deficiency in physical diagnosis as the primary factor. Inasmuch, however, as other clinicians in Colorado have noted the same discrepancies, it is fair to assume that at least a partial explanation may be found in attempted over-niceties of diagnosis.

While the tendency toward greater skill in physical examinations is assuredly to be commended, a note of warning may be sounded lest, in our enthusiasm for that which is new, due importance be not attached to the old-fashioned methods without which positively accurate results are often unattainable. Correctness of interpretation is often quite as essential in the problem of diagnosis as a keen recognition of somewhat obscure physical signs. Logical deductions must be based on a comprehensive and selective review of all clinical and laboratory data, rather than on a single objective manifestation of uncertain significance. In the formation of positive conclusions a wise discrimination is necessary regarding the relative importance and frequency of the various physical signs of incipient tuberculosis. An appreciation of their comparative value is not always afforded when efforts are directed largely to the perfection of ultra-refined aspects of diagnosis. Some thought to be characteristic of the disease are inconstant and others devoid of definite meaning.

For practical purposes a working familiarity with the more common signs, and their grouping in connection with suggestive facts pertaining to the history and symptoms, are more necessary for the general practitioner than attention to features of exceptional occurrence, difficult recognition and doubtful import. That physicians in some instances are prone to find too much on physical examination is evidenced by the multiplicity of detail sometimes reported with reference to the finer shades of respiratory sounds in different regions of the chest.

It is impossible here to discuss at length the merits of the slight modifications of normal vesicular respiration occasionally recognized at a very early age, or to review the diagnostic value of deviations from normal apical percussion outlines of clinical interest in cases with moderate involvement.

In the presence of tiny foci of infection it may be difficult to appreciate visual changes in the contour or movement at the apex. Palpation at such a time may also fail to disclose a retardation or deficiency of the inspiratory expansion. Even a well-defined variation from the normal percussion boundaries may not be indicative of tubercle deposit. In cases with moderate infection it is not invariably pronounced, and at an incipient stage is usually absent altogether. The accurate determination of resonant borders in early phthisis is an accomplishment not easily acquired save by constant practice. Krönig has called attention to a typical condition of the lungs found in some patients with nasal obstruction. He reports a fibrous induration with collapse and shrinkage of the apex as the result of the inhalation of dust by such individuals. In spite of the percussion signs suggesting tuberculosis, this may be excluded on the basis jointly of the clinical course, the negative bacteriologic findings, and the failure of the tuberculin reactions. Philip, of Edinburgh, deprecates the want of refinement in percussion methods, and calls attention to a certain adaptation of this means of diagnosis called "tidal percussion." This consists of percussing alternately during expiration and full inspiration in order to determine the limitation of tidal movement and ascertain the degree of functional activity. While recent clinical observations have tended to corroborate the advantages said to be acquired by the application of this method in some instances, the fact remains that its significance is subject to considerable variation.

AUSCULTATORY SIGNS

Inspection, palpation and percussion are often available for the recognition of long-standing tuberculous processes, and are occasionally of contributory value in cases of recent infection. In general practice, however, the diagnosis of incipient phthisis will be made in most cases through recourse to auscultation. As a rule, in cases of recent infection the evidence to be derived by this method relates to the detection of fine, adventitious elements more than to definite changes in the pitch, quality, rhythm or intensity of the respiratory sounds. It has been my observation that the auscultatory signs of chief importance in early tuberculosis consist of faint, scarcely recognizable clicks, at the end of inspiration following a cough, sometimes without pronounced modification of respiratory sounds. They are often obscure if the cough be too violent or the inspiratory effort unduly vigorous. While especial significance attaches to the presence of unilateral râles at the apex, a not uncommon and sharply localized site of their occurrence may be under the clavicle, in the axilla, and in the upper interscapular space frequently opposite the spine of the scapula. I have occasionally recognized very tiny, semidry clicks in the interscapular region without other physical evidence of the slightest tuberculous involvement either in this region or at the apex.

In emphasizing the vast importance of râles as a factor of diagnosis, due cognizance is taken of the conflicting opinions entertained by other observers. Some regard a roughened breathing, variously termed "cogwheel," "harsh," "rude," "interrupted" and "granular" respiration, as of paramount value in the early determination of tuberculous lesions. Turban regards the so-called rough breathing as one of the most important changes of the normal breath sounds. He distinguishes this from ordinary vesicular respiration "in that it appears to be composed of a series of sounds in rapid succession." Grancher alludes to this anomalous form of respiration and calls attention to the absence of softness or smoothness. He describes a harsh respiration, which may be dry, hard or rasping, with or without adventitious sounds, and occurring both in inspiration and expiration, especially the former. Turban, Grancher and Dettweiler have ascribed the origin of rough breathing to a partial obstruction of the finer air passages. It is, of course, readily conceivable that an initial tubercle deposit may encroach on the finer bronchioles to such an extent as to render the air channel narrow and uneven. A slight obstruction of the air current produced by the localized congestion of the mucous membrane in tiny bronchial ramifications may modify the character of respiratory sounds sufficiently to suggest their designation as "rough," "harsh," "interrupted" or "sticky." Sahli believes that this form of breathing is attributable to the presence of secretion in the bronchioles. He states: "When these added sounds can be distinctly differentiated as such from the breath sounds, we speak of râles; if not, they merely give an impure, rough character to the vesicular breathing."

It is apparent that the same sound may be variously interpreted according to the understanding and experience of examiners. It may remain largely a matter of personal equation whether or not the breath sounds in certain instances may be designated as merely impure and roughened or of the vesicular type supplemented by adventitious sounds. In making case records it has been my custom for many years to define apical sounds more or less analogous to what some would term rough breathing as "very fine, semidry râles." Their distinct recognition, of course, justifies their inclusion in the category of râles, although they are quite different in character from the crackling or bubbling adventitious sounds so common in tuberculosis. Roughness of the breath sounds as contrasted with the ordinary smoothness or softness of the respiration is undoubtedly of some provisional diagnostic value in obscure cases. The significance, however, of these modifications of normal breath sounds, including feebleness of respiration, appears decidedly inferior to that of localized râles which are so frequently overlooked. As the descriptive appellation "harsh" is used synonymously with sharpened, puerile breathing relating strictly to an increase of intensity, it is apparent that to avoid confusion this term should not designate the impure vesicular respiration of early phthisis.

INTERPRETATION OF HEMORRHAGE

The diagnostic significance of pulmonary hemorrhage is sometimes subject to erroneous interpretations. A hemorrhagic onset of tuberculosis is not uncommon even without previous subjective symptoms or physical signs. A strong suspicion of incipient tuberculosis is, therefore, awakened by the occurrence of hemorrhage in individuals of apparently robust health. If, however, there are associated loss of weight, elevation of temperature and cough, although without physical signs, a provisional diagnosis of tuberculosis may be warranted. In the absence of definite physical evidences it is important to eliminate all other conditions possibly responsible for hemoptysis. A moderate number of hemorrhagic patients have been observed who presented every apparent subjective indication of pulmonary tuberculosis, yet the bleeding was found dependent on other causes. I have elsewhere reported instances of cardiac disturbance, including mitral disease, a dilated and hypertrophied right ventricle, cases of purpura hemorrhagica and vicarious menstruation, illustrating the danger of mistakes in diagnosis through incorrect interpretations of recurring pulmonary hemorrhage.

Pulmonary syphilis and chronic influenza are not such infrequent causes of erroneous diagnosis as might perhaps be expected. The clinical manifestations and even the physical signs may resemble so closely those of pulmonary tuberculosis as to preclude their differentiation save on the basis of the bacteriologic findings or specific tests.

MANAGEMENT OF PATIENTS

To resume the summary of the cases recently observed it may be stated that several invalids presented the history of a six months' or one year's sojourn in local sanatoria, and some reported an attempted enforcement of the so-called "sanatorium régime" outside of institutions. Many had been informed by their medical attendants that the disease could assuredly be arrested at home, that climate was of no avail, and that tuberculin therapy was of undoubted efficacy as a routine measure of treatment. A large number had been subjected to this, and a few to medication with the various vaccines. The extent to which the mercury treatment had been employed is also worthy of note. Superalimentation had occasionally been enforced, regardless of digestion, circulation or elimination. Fresh air had often been sought even at the expense of fatigue, the necessity of rest in addition to outdoor living not always being recognized as essential. Varying degrees of exercise had been permitted or demanded, irrespective of the temperature or pulse. In many cases attention to the smaller details of therapeutic management had been strangely lacking, although much greater insistence had been made than in former years on the observance of precautionary measures.

Almost without exception patients had been instructed with reference to the necessity of rigid compliance with hygienic rules. In general, emphatic attention had been called to the responsibility devolving on the consumptive to safeguard the interests of others. Not infrequently, accompanying members of the family were found in a state of anxious trepidation from the fancied dangers of exposure, notwithstanding a proper disposal of the sputum and the maintenance of the utmost cleanliness. Laudable as have been the personal efforts in the cause of prevention, it has occasionally appeared that a higher regard was exhibited for the preservation of others than for the protection and restoration of those already afflicted. In one instance, a young woman of neurotic type with moderately advanced phthisis was advised in detail as to her obligation to society, but received almost no information concerning the conservation of strength and the proper individual application of the principles of daily living. In other cases of incipient type the hygienic and dietetic management had been elaborated to such an unnecessary degree as to result in the later moral incapacitation of the invalid. Habits of idleness were engendered which at a later time had been extremely difficult to overcome. An aversion to employment of any kind is not uncommonly noted among individuals who have been subjected for prolonged periods to the demoralizing and degenerative effect of protracted indolence.

The important educational influence accruing from residence in institutions for consumptives has sometimes been perverted to such an extent as to render the patient difficult of subsequent management. Preconceived ideas as to the possible gravity of the condition, the avoidance of drugs and the relative value of various therapeutic procedures have often become a source of considerable embarrassment in the treatment of the clinical manifestations and in the resourceful control of the tuberculous individual. An unreasoning prejudice against the administration of any medicine whatever is somewhat in vogue. In consequence it is sometimes hard to overcome the scruples of phthisical patients against the judicious administration of remedies to control untoward symptoms. Invalids trained to the doctrine of medicinal nihilism are not inclined to yield a ready assent to the employment of appropriate medication even for the suppression of pulmonary hemorrhage, the restoration of disordered digestion, and the relief of various disturbed functions.

There has been displayed at times an unfortunate neglect to observe the importance of an appropriate social environment. The quiet régime of invalidism has often been found seriously disturbed by accompanying members of the family, and particularly by the presence of little children. While in some cases a discreet and intelligent companion may aid in promoting the comfort and contentment of the invalid and insure a more faithful compliance with instructions, it is impossible to overestimate in others the injury inflicted through the absence of tact, perversions of judgment and obliquities of disposition. Children, through the necessity for added care and the greater difficulties in securing suitable accommodations, incumber to no small extent the progress of tuberculous invalids. While so delicate a matter must remain a subject for careful individualization, experience has shown that in the majority of cases the most satisfactory results are attained by the segregation of the patient. That so many children have been permitted to accompany their parents in search of health is perhaps worthy of comment.

A considerable number of patients have presented the history of a severe pulmonary hemorrhage immediately preceding their departure from home. Not infrequently this has been followed by recurrences *en route* and during the first few days in Colorado. It is found that a rather large proportion of the hemorrhages observed are but repetitions of an initial hemorrhage experienced shortly before arrival. While approximately but one-fourth of all invalids may be expected to exhibit a recurrence in Colorado, this proportion would be materially diminished were patients cautioned to defer their journey until the tendency to hemorrhage had been suppressed.

SENDING INDIGENT PATIENTS TO HEALTH RESORTS

Attention has been called by various writers to the undesirability of sending indigent consumptives to health resorts. While emphasizing the folly of permitting destitute invalids who are hopelessly advanced to experience inevitable hardships, a difference of opinion may well be entertained as to the expediency of restricting the importation of those not absolutely impecunious. Under certain conditions of supervisory direction a limited financial status is no insuperable obstacle to recovery. Despite embarrassed resources, final success may be achieved as a result of unusual opportunities which cannot always be attained at home. This subject is worthy of more extended consideration than is possible at this time, but attention may be called to the importance of ascertaining accurately in advance as to the expense necessary to provide proper accommodations, and to the likelihood of obtaining light out-of-door employment for those with incipient infection and dependent on their own efforts for support. That such process of reasoning is not always applied is shown by the history of a clergyman with his wife and four children reduced to the point of abject penury. He had been prevailed on to resign from a sustaining parish and seek a new field of labor in Colorado. Although contributions had been sufficient to meet the expense of transportation, no provision was made for subsequent care. The possible suffering, however, was mitigated to a degree by the fact that the general condition was excellent and the physical and bacteriologic evidences entirely negative. No response was obtained to the ocular tuberculin test.

Apropos of the foregoing considerations the brief report of the following case may be of interest:

> A young man immediately on arrival in Colorado presented a letter of introduction from an acquaintance stating that the invalid on account of the advanced stage of the disease had been denied admission to a well-known state sanatorium. A request was made that he should be cared for without expense and assisted in securing a position. The young man was exceptionally well nourished, without fever or other symptoms suggestive of tuberculosis other than the history of a slight chronic cough which had been subject to occasional exacerbations during the fall and winter months. Examination of the chest was negative, as was also the sputum.
> There was no response to the tuberculin test
> that he had been examined by the medical
> state sanatorium, who submitted to him the
> "The report of your examination yesterday
> case to be moderately advanced and suit
> we have vacancies for cases of this clas
> torium is full and we have many accepted
> to state that I should think the climate
> would be very suitable to your case."

Even on the assumption that an accurate diagnosis had been established, the unqualified statement regarding California or Texas was, to say the least, somewhat indefinite, if not equivocal. The folly of such direction is appreciated when one considers the enormous area included within the limits of what was described as an appropriate climate. Bearing in mind the vast divergence in climatic conditions it is conceivable that on the basis of the information imparted the youth might be expected to profit as well in the heat and humidity of Galveston as in the dry and rarefied atmosphere of El Paso, or in the rainy, foggy districts of California, as in the southerly mountainous regions. If the diagnosis had been correct, the advice as given was radically incomplete. Fortunately, no more serious consequences were involved than the despair incident to the alleged advanced infirmity, the disappointment resulting from the loss of a position, and the expense involved by a trip across the continent.

DEDUCTIONS

Speaking broadly, an analysis of the cases observed during the past year discloses a few significant facts. It is shown that in the present zeal to recognize tuberculosis at an early period an increasing number of patients are hurried to sanatoria or health resorts on a mere suspicion of the infection. Patients without well-defined constitutional symptoms or physical signs are thus subjected to great hardships incident to change of residence, loss of business, separation from family, and other deprivations. It is well known that in many sanatoria an absolute diagnosis is often quite impossible, as approximately 50 per cent. of the inmates do not have tubercle bacilli in the sputum, while very many are without loss of flesh, elevation of temperature, or acceleration of pulse.

It is also clear that for other patients disastrous delays in seeking climatic aid are occasioned by the enthusiasm of medical attendants relative to the supposed advantages of treatment in back yards. In view of recent observation it is impossible to avoid the conclusion that faith in the curability of tuberculosis at home is responsible in large measure for the desperate condition of many consumptives who finally make the journey to a distant clime.

Evidence is not wanting to suggest that rational ideas of management are not always entertained concerning a class of people demanding the greatest conservatism and stability of judgment. Not only are misconceptions sometimes exhibited relative to the efficacy of rest, discretion in diet and caution in specific medication, but delusions as well regarding the value of climate in properly selected cases. Were an unreasoning prejudice replaced by a more accurate knowledge of the various climatic attributes which are capable of producing a direct influence on the organism, much of the wretchedness and disappointment resulting from injudicious advice would assuredly be averted.

Waiving any discussion concerning the comparative merits of the sanatorium and a wisely directed climatic change, it may be submitted that patients in comfortable circumstances should receive such advice as will offer the most favorable opportunities for a speedy restoration to health. It has been amply demonstrated that a large proportion of patients in the incipient stages, through proper methods of living and supervision, may secure an eventual arrest of the infection. It has also been shown by autopsy investigations that this occasionally takes place as a result of inherent individual resistance, notwithstanding unhygienic surroundings, excessive exposure and improper food or clothing. While in many early cases the patients are likely to exhibit gratifying improvement without recourse to change of climate, it does not follow that all patients in incipient stages can achieve a complete and enduring arrest, although the balance may be turned temporarily in favor of recovery. On the other hand, despite strict conformity to a suitable régime at home, procrastination in seeking climatic aid is often attended by unfortunate results.

The choice of climate should resolve itself in all cases into a question of individual fitness. The peculiarities of temperament, the widely differing pathologic processes, the degree of functional disturbance, and other important considerations, emphasize the importance of the utmost discrimination in the matter of climatic selection. This should be adjudged for each pulmonary invalid strictly on the merits of the case, with full cognizance of the import attaching to all modifying circumstances.

It is essential that consumptives, regardless of their status, should be duly impressed by their local physicians with the necessity of conforming to systematic management. That highly improper instructions have been given in so many cases seems almost incredible.

In May of the present year I received the following letter from an inmate of a sanatorium in another state: "I am a patient of Dr. ———, and he advises my trying Estes Park for the summer. He has referred me to you for information regarding the accommodations." In my reply attention was called to the fact that it would be impossible to give detailed advice without definite knowledge as to his individual needs and requirements. A few weeks subsequently the patient reported in person that he had been instructed to consult me solely with reference to accommodations; that his medical adviser had imparted full information as to his condition, and that a physical examination or medical supervision during the summer months was unnecessary. The patient was much emaciated, markedly dyspneic, with pronounced elevation of temperature and greatly accelerated pulse, and yet contemplated, under the advice of his physician, a sojourn in an altitude of 7,500 feet. It was ascertained that for six years the patient had remained under the care of the same medical attendant and exhibited at no time evidence of material improvement. There had been a loss of twenty-eight pounds in weight, a daily elevation of temperature of 100 F. or over, and constant shortness of breath. Despite the occurrence of several hemorrhages, tuberculin had been given during a continuous period of two years, a maximum dose having been reached of 650 milligrams. It was stated to the patient that the results were eminently satisfactory, but that a temporary change to a higher elevation was desirable.

Some significance attaches to the fact that similar errors of diagnosis and treatment have been perpetrated not solely by general practitioners (as might have been supposed), but also by those whose opportunities and equipment should have precluded such possibility. It has been my observation that in the majority of cases the family physician has not shirked his responsibilities in the treatment of pulmonary invalids. Others through literary contributions have accomplished much good in arousing the interest of the profession and in spreading the cause of education among the masses.

Laboratory opportunities and equipment, an aptitude for sociologic study, administrative qualifications and years of scientific research, no matter how capable and conscientious the individual, do not always render him a skilful clinician. A satisfying direction of the pulmonary invalid in individual instances may require of the physician more than skill in diagnosis or familiarity with modern therapeusis. For the wise preliminary guidance of these patients the necessary qualifications are manifold and most exacting. Comprehensive attention to special indications representing questions of personal equation is sometimes possible only by dint of much interested effort. It is primarily essential to conduct a careful investigation not only of all phases of the disease, together with its possible complications, but also of all factors pertaining to the patient, including temperamental proclivities, financial resources, domestic relations and social tendencies. Only from a critical analysis of the various features relative to the invalid and an infinite regard for detail may the general principles of treatment be applied to the best possible advantage. While an aptitude for work of this character may not always be expected of busy practitioners, it is nevertheless fitting to emphasize its importance that the interests of consumptives may be more fully subserved. Finally, in the diagnosis and management of tuberculosis it is well to follow the scriptural advice, to "prove all things; hold fast to that which is good."

1437 High Street.

MODERN ANTISEPTIC SURGERY

AND THE RÔLE OF EXPERIMENT IN ITS DISCOVERY AND DEVELOPMENT [*]

W. W. KEEN, M.D., LL.D.
PHILADELPHIA

The subject naturally divides itself into three parts: (1) the conditions before the introduction of the antiseptic method by Lister; (2) the means by which his system was discovered and developed, and (3) the conditions existing after the introduction of the method, i. e., at the present time.

My surgical life covers all three of these periods since I graduated in medicine in 1862, some years before Lister began his work. I have, therefore, fought my way from the horrors of the preantiseptic days up to the delights of the present antiseptic days.[1]

I. THE PREANTISEPTIC PERIOD

In my early surgical experience every accidental wound and every surgical operation (that is, an intentional wound) was followed by inflammation and suppuration, i. e., the discharge of "pus" or "matter." This was not only constantly expected as an unavoidable process of Nature and believed to be needful for healing, but was constantly realized. Hence the pus was called "laudable" pus! How well I remember forty years ago at the beginning of each winter's session when I was the assistant of the late Professor Samuel D. Gross, his turning to the orderly and saying to him, "To-morrow, Hugh, I shall lecture on suppuration. Go over to the hospital in the morning and get a cupful of pus for my lecture." Pus, mark you, was always "on tap," so to speak, though the little hospital contained only a dozen beds!

Perhaps the best way to give the reader an idea of wound conditions at that time will be to describe an ordinary operation and its results. We will suppose that it is an amputation. The surgeon approached the operation with the clean hands of a gentleman. He usually wore an old coat covered with dried blood spots from previous service. His finger-nails very likely were long and no special attention was given to them. The instruments were taken out of a velvet-lined case and were as clean as ordinary table-knives would be. The operation was done without any preliminary cleansing of the skin other than to remove any visible dirt. If the knife happened to fall on the floor it was picked up, rinsed in a basin of ordinary water and used as it was. The marine sponges then always used were washed clean in ordinary water and used over and over again even after being saturated with foul pus. The blood-vessels were tied with ordinary silk; one end was cut short, the other one hung out of the wound. After an amputation of a fleshy thigh I have often seen 25 or 30 such "ligatures," as they are called, gathered into two bundles, one at each end of the wound. The flaps were then sewed together with an ordinary needle and thread and the stump dressed first with an old rag (which, however, would be ordinarily clean) or scraped lint spread with some simple grease. Over that would be placed some other rags, lint, cotton, or other dressing, and finally a bandage. During the Civil War these greasy dressings gave place to simple cold-water dressings.

By the second day the patient would begin to have considerable fever. By the third or fourth the temperature would rise to what we now know (for medical thermometers were not in general use in that early day!) to about 103, 104 or 105 F. Then we would poultice the wound. Every few hours the patient would be disturbed, a new poultice put on to replace the old one, now cold, foul and ill-smelling, and by this time bathed with pus. I have often seen the pus escaping by the tablespoonful and the wounds alive with squirming maggots resembling chestnut worms. By this time also it was hoped that the silk ligatures, with which the arteries had been tied, had literally "rotted" loose and each one of them was gently pulled on to the discomfort of the patient. Care was taken that the ligatures with knots tied on them (in order to distinguish those that secured the large blood-vessels) should not be pulled on severely until probably the tenth or twelfth day. Meantime the patient was tossing about the bed with pain, with thirst, without appetite, without sleep except such as morphin would secure. This at the same time dried up all the secretions, producing constipation and other evils.

By about the tenth to the fourteenth day, suppuration having been fully established and quantities of pus pouring from the wound, the fever would subside and the wound would begin slowly to heal. Of course, the healing could not be complete so long as the silk ligatures were still protruding from the wound. Sometimes they did not become detached for even months or years, but more commonly all of them would rot loose in from ten days to three weeks. When the silk ligatures on the large blood-vessels came away, if the healing process had formed in the blood-vessels a firm clot, which had become adherent, and, so to speak, "corked" it up, all went well. But, as very frequently happened, when the ligature and the rotten end of the artery were pulled off and there was no clot to act as a stopper, "secondary[2] hemorrhage" followed. This often came on after the patient's wound had been dressed and the surgeon had left, and, if so, very likely the first notice that the nurse had that anything was wrong would either be the gasping for breath of the patient or his moans and cries, or sometimes by the blood which had not only saturated the mattress, but had even appeared in a pool on the floor.

---

[*] This paper is one of the series prepared for and reprinted by the Council on Defense of Medical Research of the American Medical Association for circulation among the public. This fact accounts for its popular style and the frequent use of *non-technical* terms. Twelve of these pamphlets are now ready, taking up the relations of animal experimentation to ethics, diagnosis, cancer, vaccination, the live stock industry, tuberculosis, typhoid, dysentery, rabies, surgery, internal secretions, protozoan tropical diseases, etc.

[1] In this article I use the *word antiseptic* as the more popular one to include also the aseptic method.

[2] So called to distinguish it from "primary hemorrhage," *i. e.* the bleeding occurring at time of the accident or operation.

How fatal were such hemorrhages may be seen from the fact that in 2,235 cases of hemorrhage in the Civil War 61.7 per cent. of the patients died.[3]

I shall never forget one night about ten days after the battle of Gettysburg, when it was my business as "officer of the day" to attend to all emergency cases. That night I was called to five cases of secondary hemorrhage. To indicate what a difference there is between modern and ancient conditions, in the thirty-four years since October, 1876, when I began the practice of the antiseptic method, I have not seen as many cases of secondary hemorrhage as I treated in that one night.

It was a rare thing for any patient after such an operation to get well under three or four weeks, and it was not uncommon for healing to be delayed for three or four months, so that, in spite of the great mortality, the wards of the hospitals were cumbered with convalescent patients. The rare case in which healing took place by "first intention," i. e., at once, was recounted as a triumph. To-day it is precisely the reverse. The case in which healing does *not* occur primarily and at once is regarded as a disaster.

But a prolonged convalescence was the least of the evils to which a patient was subject. A large majority of the wounds were followed by erysipelas, by lockjaw, or by blood poisoning, and hospital gangrene sometimes became a veritable plague. Gangrene in various forms during the Civil War was rife and often fatal. In 2,503 cases 1,142 patients died, a mortality of 45.6 per cent.[4] In one variety which was frequent, hospital gangrene, a simple flesh wound scarcely larger than the bullet which made it, became larger and larger till a hand would scarcely cover it and it would eat into the tissues until one could put half his fist into the sloughing cavity.

Of 505 cases of lockjaw (tetanus), 451 were fatal, a mortality of 89.3 per cent.[5] Pyemia or blood poisoning was terribly frequent and almost as fatal as it was frequent, for of 2,818 cases in the Civil War 2,747 patients died, or 97.4 per cent![6] When a joint was opened or wounded, the result was frequently either amputation or death, or not uncommonly amputation and death. Of 2,382 wounds of the knee-joint alone for which amputation was performed 1,212 patients died, a mortality of 51 per cent., and of 973 similar wounds for which amputation was not performed 591, or 61 per cent. of the patients died.[7]

Fractures, as most people know, are divided into two kinds: simple fractures in which the skin is unbroken, and compound fractures in which the broken bone protrudes through the skin. Simple fractures nearly always heal with relatively little pain and slight fever; but in the preantiseptic days when the skin was broken and the bone protruded two out of three patients with these compound fractures were sure to die.

Moreover, certain regions of the body were forbidden ground unless the surgeon were absolutely compelled to invade them. No one would open the head if he could possibly avoid it. No one would dare to make an incision through the abdominal wall into the cavity of the abdomen unless a bullet or a dirk had gone before him and opened the way. The reason for our hesitation was that death stalked behind us.

How eloquent is the statement of Sir Samuel Wilks,[8] that "the change came home to me in an almost startling manner from what I witnessed in the post-mortem room. Some time before [i. e., before Lister's discoveries], when reading a paper on pyemia (blood poisoning), I had no difficulty in collecting 100 cases which had occurred within a very short time previously, when suddenly this terrible malady disappeared—it was gone never to return." So, too, lockjaw (tetanus), except in accidental cuts that have been neglected and have not received proper surgical care, has almost completely disappeared. Again, at the present day one practically never sees erysipelas after operations; and in order to find illustrations of hospital gangrene to show to my classes for the last thirty years I have had to rely on pictures from the Surgical History of the Civil War and other similar sources, for I have not seen a single case in private or hospital practice since I first adopted the antiseptic method in 1876.

II. THE DISCOVERY AND DEVELOPMENT OF THE ANTISEPTIC METHOD[9]

Neither time nor space will allow me to describe the many earlier steps. Schwann, in 1837, in studying putrefaction, reached the conclusion that it was not the gases of the air, especially the oxygen, as was then universally believed, that caused putrefaction, but organic particles which floated in the air and which could be destroyed by heat. In 1854 Schröder and Dusch showed that putrefaction did not occur in organic fluids in flasks if the air entering the flasks was simply filtered through cotton wool. Pasteur, in 1864, showed that it was necessary neither to heat the air nor thus to filter it, for if the air merely entered through a tortuous tube in which the dust could settle before it reached the fluid no change took place in the fluid, or if flasks containing a material which would putrefy were left open in a place where the air had been undisturbed sufficiently long to allow the dust to settle, as, for example, in a cellar, no decomposition took place and no growth appeared in such fluids.

Lister naturally was profoundly impressed by these studies of Pasteur and he proceeded to make many experiments to confirm or disprove them. Among them I will only relate the following:[10] Lister filled four glass flasks one-third full of urine and drew out the neck of each flask with a spirit lamp into a tube less than one-twelfth of an inch in diameter. Three of these long open tubes were then bent at various angles downward, while the fourth, equally narrow, was left short and vertical. Each flask was then boiled for five minutes, after which they were left with the ends of the small necks still open. Through these open mouths the air, including its oxygen, would pass out during the heat of the day and pass in during the colder night. The boiling was to kill any organisms in the liquid or on the sides of the glass. The object of the bending of the three necks downward was to allow the air to pass in and out, but to intercept the particles of dust, which, according to the germ theory, caused putrefaction. The germs, being heavier than air, could not rise in the bent necks. The fourth neck, however, being short and vertical, not only allowed the air to pass in and out, but gave a very narrow but real opportunity for dust and germs to fall into the liquid. If any of these were living organisms they could produce putrefaction. In a short time the vessel with the short and vertical neck showed growths of mold and the liquid changed its color, showing chemical changes; but in the three flasks with bent necks the urine *after four years was entirely unaltered.* A year after the commencement of the experiment a little of the urine in one of the flasks with a bent neck was poured into a wine-glass; it had not lost its original acidity and normal odor and a microscope showed not the minutest organism. In two days it was most offensive, and under the microscope already teemed with organisms. The other three flasks were subjected to a further severe and rather amusing test. Two years after the beginning of the experiment Lister had to transport them from Glasgow to Edinburgh on the railway when he was appointed to the chair of surgery in Edinburgh. He took charge of these flasks himself, "nursing them carefully," as he says, "to the amusement of my fellow travelers." In the drive from the station to his house the violent rocking of the carriage churned up the contents of the flasks till the upper part was full of a frothy mixture of this proved putrescible liquid with the atmospheric gases; yet after two years more no decomposition had taken place.

The Lister number celebrating the fiftieth anniversary of his receiving his degree, and Lister's Huxley Lecture in the same journal, Oct. 6, 1900, and Cameron's "Lister and the Evolution of Wound Treatment, etc.," Glasgow, 1907.

[10] Lister: ii, 173; Brit. Med. Jour., 1871, ii, 225.

The explanation of this convincing experiment was simply this: The germs in the atmosphere could not rise against gravity in any of these tubes bent downward and so could not gain access to the urine. This easily preserved a decomposable fluid for four years, although the air passed in and out freely every day. But the urine in the flask with the straight but very narrow neck in a few days had undergone decomposition. The only difference between the flasks was that the three bent tubes prevented the entrance of the germs, though not of oxygen or other constituent of the air, while the straight but equally narrow tube allowed the germs to enter through in very small quantities, and yet these few grew and produced putrefaction.

In order still further to confirm this experiment, however, Lister tested these bent tubes by the condensed beam of light which Tyndall had used and found that they were optically empty.[11]

These experiments convinced him that it was not the oxygen or any other gas in the air that caused inflammation and suppuration, but that these were caused by *the minute organisms suspended in the air.* In dressing a wound, then, the problem was how to exclude not the air or its oxygen, which was impossible, but how to exclude the organisms in the air. This could be done by applying a dressing saturated with some material capable of destroying the life of these germs. This was the basis of the antiseptic method.[12] It must be remembered that at that time we were wholly ignorant of what now everybody knows, that there are hundreds of different kinds of germs or bacteria. Even the greatest scientists were then groping in the dark seeking for the light by observation and especially by experiment.

About that time Lister was much struck with an account of the effect of mingling phenol (carbolic acid) with the sewage of the town of Carlisle, England.[13] He proceeded, therefore, to experiment with it in compound fractures. I have already stated how fatal a compound fracture was in those days. Indeed, Mr. Syme, the great Edinburgh surgeon, predecessor and father-in-law of Lister, was inclined to think that, on the whole, "it would be better if in every case of compound fracture of the leg amputation were done without any attempt to save the limb." The marked success which followed his dressing these compound fractures[13, 14] with carbolic acid led him then to experiment with its use in abscesses.[13, 14, 15] This was followed again by such remarkable success that he was led to try it in accidental wounds and finally to intentional and extensive wounds, i. e., surgical operations.[16]

Practically the progressive introduction of the antiseptic system from compound fractures up to deliberate surgical operations was one vast experiment in the human living body—an experiment justified, as all the world well knows, by its splendid and continuing results. Yet when in 1880 or 1881 Lister wished to make additional experiments on animals to perfect his method still further, so stringent was the law in England that he was obliged to go to the Veterinary School at Toulouse, France.[17]

Like many surgeons, Lister had noticed the fact that a needle or a bit of glass would often lie for an indefinite period in the body without producing inflammation or pus, but that a bit of silk or linen thread was sure to produce pus. He believed the reason was that the thread was porous and that its interstices contained these germs which no one had then seen and identified, and that they gave rise to decomposition and produced the pus. So, Lister, from his previous experiments with phenol (carbolic acid), believed that if the thread with which an artery was tied were steeped in phenol and both the ends of the silk were cut short it might be left in the wound without producing any inflammation or suppuration. The wound could then be closed at once—an immense gain, for it would heal at once. "Before applying these principles on the human subject," he says, "I though it right to test them on one of the lower animals."[18] Accordingly, Dec. 12, 1867, he tied the great blood-vessel in the neck of a horse, having steeped the silk for some time in a solution of phenol. Both ends were cut short, the wound was entirely sewed up and treated with phenol dressings. Ten days after the operation the dressings were removed, the wound was healed, and there was no pus! Thirty-nine days after the operation he carefully examined the artery which he had tied. The operation was a complete success, the blood current had been entirely arrested and the thread had been covered in by dense fibrous tissue. Thus encouraged, he says: "I felt justified in carrying a similar practice into human surgery."[19] Jan. 29, 1868,[20] he saw a woman, 51 years old, with an aneurism as large as a large orange in the upper part of the left thigh. (An aneurism, I should explain, is a dilated portion of an artery, the yielding of the wall being due to disease of the wall of the blood-vessel. This dilatation continues to increase in size till finally the wall of the artery is so thin that it bursts and the patient dies from hemorrhage.) On the following day he tied the woman's artery with a piece of silk which had been steeped for two hours in phenol.

The wound was treated like that in the horse's neck, i. e., both ends of the ligature were cut short, the wound again entirely closed and a phenol dressing applied. The patient was immediately relieved of the pain she had previously experienced; she had no fever, the pulse was practically normal the entire time, and "her appetite, which had been absent during the four weeks of agony that preceded the operation, returned two days after it."[21] She made a perfect recovery. November 30, ten months after the operation, she suddenly expired. Fortunately, Lister himself had the opportunity of making the post-mortem. He found that her death was due to the bursting of a similar aneurism inside of the chest. Examining the artery which he had tied, he found that the silk had almost all disappeared, but that there was a little fluid around the remnant of the ligature, which probably would have developed into a small abscess and might have caused great mischief had she lived longer. This, therefore, suggested to him the expediency of substituting for the silk some other substance which would be more readily absorbed.[21]

In Philadelphia years before Dr. Physick had already tried animal ligatures made of buckskin, Dorsey those of kid, Hartshorn had used parchment, and Bellenger and Eve the tendon of the deer, but for various reasons these had all been abandoned. Lister determined to try catgut. Although he had great confidence in the use of catgut steeped in a solution of phenol, yet he says[22] "in order to put the antiseptic animal ligature to the test, I made the following experiment," for only by experiment in an actual living body of animal or man could the question whether it was actually safe or not be surely answered. Dec. 31, 1868, he tied the right carotid artery in the neck of a healthy calf at several places with different kinds of animal ligature, including catgut. All were cut short except one end of the catgut, which was purposely left three-quarters of an inch long to determine what would become of this foreign material. The wound was completely closed and dressed. After ten days the dressings were removed and the wound found quite dry. Thirty days after the operation Lister says, on dissection, he was struck with the entire absence of any infection or inflammatory thickening in the vicinity of the blood-vessel. On exposing the artery itself he was greatly disappointed at first to find the ligature to all appearance still there and as large as ever. On more careful examination, however, he found that this apparent ligature was not the catgut ligature at all, but that this ligature had been transformed into bands of living tissue, making the artery not weaker, as silk often did, but stronger than ever at the point where it was tied. The knots had disappeared and also the three-quarters inch of catgut purposely left. Everything had been absorbed.

Even one not a surgeon can see what an enormous difference in rapidity of healing without inflammation, pain or other serious disturbance of the body this use of catgut with immediate total closure and healing of the wound provided. Before Lister, the old ligatures hanging out in bundles were always inviting infection, suppuration, erysipelas, lockjaw, blood-poisoning, hospital gangrene and death. No patient was absolutely safe till the wound was absolutely healed and this often required weeks or months. With the catgut ligature, both ends being cut short, the wound closed at once, and, the ligature being absorbed, the wound healed in less than a week, not uncommonly in three or four days, with little, if any, immediate suffering and without any ultimate danger of those many serious complications above mentioned. But no one not a surgeon can appreciate to the full the meaning of these brief words. While the patient made a smooth and speedy recovery without complications, the surgeon slept the uninterrupted sleep of the just, secure against wearing anxiety on account of sudden hemorrhage or insidious infection. The heart-breaking tragedies which often made the surgeon wish he were a hod-carrier or even in his grave are now but specters of a horrid past.

As I have said, we had no idea at first of the enormous variety and different characters of the germs. In his early studies on putrefaction, Lister spoke of them in a general way as "germs," because the various species of plants (for they are plants and not animalculæ) had not been distinguished. Now there are scores and even hundreds of known varieties. Many of these simply cause putrefaction or decomposition and are not in themselves capable of giving origin to any particular disease. Other varieties, each one of which causes a special disease and can cause no other disease, have been isolated and identified. Some of these germs cause medical diseases, with which I have nothing to do here. The germs of lockjaw, tuberculosis, anthrax (wool sorters' disease), erysipelas, glanders, etc., are among the most virulent foes with which the surgeon has to contend.

How have these been identified and how do we prevent their entrance into the system of the patient? The process is very simple to describe, but very complicated and difficult practically. Let us take the case of lockjaw for instance. A peculiar kind of germ, looking a good deal like a tack with a straight body and a large head at one end, was discovered by animal experiments by Nicolaier in earth and dust in 1884.[23] In 1889 Kitasato, the Japanese bacteriologist,[24] first obtained it in pure culture, former experimenters having failed because they did not know that it only grows well when oxygen is excluded.

But how do we *know* that this tack-like germ and it alone is the cause of lockjaw?

First, in a patient ill with lockjaw, this particular bacillus or germ must be discovered.

Second, a pure culture of it must be produced; that is to say, the tetanus bacillus must be separated from all other germs and cultivated by itself. Third, some of this pure culture of tetanus unmixed with any other germs whatever must be injected into an animal to see point-blank whether this particular bacillus will produce lockjaw. Fourth, from the body of this animal the same germ that was injected must be recovered. Fifth, with a pure culture of this recovered bacillus the cycle must be begun over again and completed sufficiently frequently to assure the experimenter that the connection between the disease and the germ is not accidental, but essential and invariable. Sixth, no other germ used in the same way must produce lockjaw.

In this same manner the germs that produce inflammation and suppuration, which are *the* ever-present danger to the surgeon, have been identified, and also, what is equally important, the places where they and many others exist. In this way we have determined the fact that, while there are some in the air, they are few in number and so constitute a small though a real danger. But the places where they are found and are most dangerous are on the skin and clothing of the patient, the hands of the surgeon and especially under his finger nails and at the roots of his nails, on instruments, dressings, silk, catgut, and other things used for ligatures; in fact, practically every material that one can think of.

[24] Deutsch. med. Wchnschr., 1889, No. 31.

We know now how all-pervading they are. We know, too, that phenol (carbolic acid), corrosive sublimate and other chemicals, or that boiling for a certain time, or heating to a certain degree and for a certain time, will kill these germs. Thousands of such painstaking researches in test-tubes and by many other bacteriologic methods have been carried out all over the world by men either wholly unpaid, working for the love of truth and love of their fellow creatures, or paid but meager pittances. Then when a discovery seems to have been made comes the needful, the finally convincing, the unavoidable experiment—in a living body itself. The only question is should Lister have made this final test first on a horse and a calf, or on two human beings? Can any one with a sane, well-balanced mind hesitate as to the answer?

III. THE RESULTS

The results of the establishment of the antiseptic method have been so extraordinary as to be incredible were it not for ample testimony the world over. They have been already stated in part, but a few words more must be added.

At present before an operation is begun the patient's skin, the surgeons' and the nurses' hands are scrupulously disinfected, sterile gloves are usually worn and every person is clothed in a disinfected gown. The instruments, dressings, ligatures, everything that is to come in contact with the wound, is carefully disinfected. Disinfected gauze "sponges" are used once and then discarded.

It is almost impossible for any one not a surgeon to understand how different are the results from this radical change of methods. No change of climate from fierce mid-winter storms to lovely summer breezes or autumn golden harvest could be greater. Most wounds now heal within a few days, one might almost say without the patient's being sick. Compound fractures and opened joints heal as if there had been no break in the skin. Arteries can be tied anywhere without fear of secondary hemorrhage. The abdomen is now fearlessly opened.

A woman with an ovarian tumor no longer has an operation postponed until it is very dangerous but inevitable, but by early operation is relieved almost without danger, even from tumors so large as to weigh twice as much as the patient herself. When I was assistant to Dr. Washington Atlee in the late sixties, before the antiseptic period, two out of three of his ovariotomy patients died, yet he was the then most famous operator in America. Now any surgeon who loses more than five out of 100 is looked at askance by his colleagues, and many, many hundreds of cases have been operated on with a mortality falling even below 1 per cent. There is not an organ in the abdomen that has not been attacked; organs which formerly when diseased could not be touched because death was almost sure to follow are now operated on every day. In fact as I once described it, the abdominal cavity is almost the surgeon's play-ground! The stomach, the intestines, the liver, the gall bladder, the pancreas, the spleen, the kidney, every organ is operated on, and with extraordinary success. Did space permit, a more detailed statement could be given, but it could scarcely be more convincing.

In obstetrics the same happy results have followed the introduction of the antiseptic method. Puerperal or child-bed fever, which not uncommonly used to kill one-half or two-thirds or even three-fourths of the women in the maternity wards of a hospital, now is practically unknown except in the neglected cases brought into the hospital at a late date, and the preantiseptic general mortality in maternity cases has been reduced from 10 per cent. or more to 1 per cent. and less. Brain tumors, abscesses and other diseases of the brain formerly inevitably caused death, for we never dared to touch them. Now the number of recoveries is very large. Compound fractures now have a mortality of 2 or 1 per cent. or less, instead of over 60 per cent. and now very rarely require amputation; and amputations formerly followed by death in one-half the cases have a mortality of 10 per cent. or less. In general, both the soldier and the sailor are provided with the first aid packet, which contains an antiseptic dressing. This has enormously diminished the mortality of wounds received in battle.

Perhaps no better evidence of the value of the antiseptic method in civil life can be adduced than the results in three hospitals. In Munich[25] the General Hospital was excessively unhealthy. Blood poisoning was very frequent and hospital gangrene, which had appeared in 1872, had become annually a more and more frightful scourge until 1874, when *80 per cent.* of all wounds that occurred in the hospital, whether accidental or inflicted by the surgeon, were attacked by it! At the beginning of 1875 Nussbaum introduced the antiseptic treatment. From then on till Lister's visit, presumably in the summer of 1875, *not one single case* of hospital gangrene had occurred and only one case of blood poisoning, and that a doubtful one. Erysipelas was rare and mild instead of being very prevalent and severe, and the convalescent wards, which formerly had been filled to overflowing, stood practically empty. In Halle,[26] Volkmann was operating in an extremely unhealthy hospital in small, overcrowded wards, with the toilet rooms opening directly into them and a large drain running directly underneath. It was so bad that it had been condemned to demolition. After his introduction of the antiseptic method in 1872, no single patient suffering from compound fracture in which conservative treatment was attained had died either from the fracture or from a necessary amputation, nor was there a single death from secondary hemorrhage or gangrene. No case of blood poisoning had occurred for a year and a half, though 60 amputations had been done. Hospital gangrene had entirely disappeared and erysipelas was extremely rare and mild.

Perhaps, however, the most extraordinary success was obtained by Lister[27] in his own wards in Glasgow. Lister was professor of surgery in Glasgow from March, 1865, till the autumn of 1869, but in that brief period he introduced measures that were absolutely revolutionary. The Royal Hospital in Glasgow was overcrowded, and in some parts of the building the conditions were so frightful that the wards had to be entirely shut up for a time. Lister's own account of this is interesting. He says:

> "A crisis of this kind occurred rather more than two years ago in the other male accident ward on the ground floor, separated from mine merely by a passage twelve feet broad, where the mortality became so excessive as to lead, not only to closing the ward, but to an investigation into the cause of the evil, which was presumed to be some foul drain. An excavation made with this view disclosed a state of things which seemed to explain sufficiently the unhealthiness that had so long remained a mystery. A few inches below the surface of the ground, on a level with the floors of the two lowest male accident wards, with only the basement area, four feet wide, intervening, was found the uppermost tier of a multitude of coffins,

---

[25] Lister, ii, 248; Brit. Med. Jour., 1875, ii, 769.
[26] Lister, ii, 250; Brit. Med. Jour., 1875, ii, 769.
[27] Lister, ii, 124; Lancet, 1870, i, 4, 40.

> which had been placed there at the time of the cholera epidemic of 1849, the corpses having undergone so little change in the interval that the clothes they had on at the time of their hurried burial were plainly distinguishable. The wonder now was, not that these wards on the ground floor had been unhealthy, but that they had not been absolutely pestilential. Yet at the very time when this shocking disclosure was being made, I was able to state, in an address which I delivered to the meeting of the British Medical Association in Dublin[28], that during the previous nine months, in which the antiseptic system had been fairly in operation in my wards, not a single case of pyemia [blood poisoning], erysipelas, or hospital gangrene had occurred in them; and this, be it remembered, not only in the presence of conditions likely to be pernicious, but at a time when the unhealthiness of other parts of the same building was attracting the serious and anxious attention of the managers. Supposing it justifiable to institute an experiment on such a subject, it would be hardly possible to devise one more conclusive.
>
> Having discovered this monstrous evil, the managers at once did all in their power to correct it. . . . But besides having along one of its sides the place of sepulture above alluded to, one end of the building is coterminous with the old cathedral churchyard, . . . in which the system of "pit burial" of paupers has hitherto prevailed. I saw one of the pits some time since. . . . The pit, which was standing open for the reception of the next corpse, emitted a horrid stench on the removal of some loose boards from its mouth. Its walls were formed on three sides of coffins piled one upon another in four tiers, with the lateral interstices between them filled with human bones, the coffins reaching up to within a few inches of the surface of the ground. This was in a place immediately adjoining the patients' airing ground, and a few yards only from the windows of the surgical wards! And the pit which I inspected seems to have been only one of many similar receptacles, for the *Lancet* of September 25 contains a statement, copied from one of the Glasgow newspapers, that "the Dean of Guild is said to have computed that five thousand bodies were lying in pits, holding eighty each, in a state of decomposition, around the infirmary."

When to all this is added the fact that the large fever hospital was separated from the surgical hospital by only eight feet, that Lister's hospital of nearly 600 beds was cramped in area and almost always full to overflowing, and that he was operating, it might almost be said, in a charnal house, yet that those wards were continuously and conspicuously healthy and enjoyed for "three years immunity from the ordinary evils of surgical hospitals under circumstances which but for the antiseptic system were specially calculated to produce them,"[29] we stand convinced by such a huge unintentional experiment on man himself.

Were not results such as these sufficient to justify the experiments on animals as related by Lister himself and here quoted, by which such blessed relief has been brought to mankind?

What was seen in Glasgow has occurred all over the world. The surgical revolution of the last thirty years is the most momentous in the entire history of surgery. In every science—chemistry, engineering, botany, physics, electricity—the era of precise experiments has been the era when enormous and constant progress has been made. Medicine is no exception. We have closely studied disease by various observational methods, and clinical observation for two thousand years had slowly advanced our knowledge up to a certain point. Then experimental research, which employed methods of precision, varying conditions at will, noting the different results, and multiplying the experiments at will instead of waiting, it might even be years, until Nature's second experiment occurred, began its work; and in the past thirty years experimental research has produced a more fruitful harvest of good to animals and to mankind than the clinical observation during thirty preceding centuries.

But we are far from having attained perfection. In medicine and in surgery many problems of disease and death are still awaiting solution and can only be solved by the experimental method. A number of organs in the body are as yet inaccessible and others have functions of which we know little or nothing. Many operations ought to be bettered in method and in results. The causes of many diseases, such as cancer, scarlet fever, measles, whooping-cough, etc., are as yet unknown. To dispel all this ignorance and discover a cure for all these and other diseases is the earnest wish of wise and humane experimenters the world over. Shall the community aid these humane life-saving efforts, or shall they by restrictive legislation call a halt and let death slay our fellow creatures and especially our dear children? The answer is clear. It will never be other than an emphatic NO to the latter cruel course.

1729 Chestnut Street.

THE OBLIGATIONS OF THE UNIVERSITY TO MEDICAL EDUCATION *

HENRY S. PRITCHETT
President of the Carnegie Foundation for the Advancement of Teaching
NEW YORK CITY

In an admirable paper before the Sixty-fifth Convocation of the University of Chicago, in December, 1907, Dr. William Henry Welch,[1] professor of pathology in Johns Hopkins University, pointed out with clearness that the historical and right home of the medical school is the university, and that it should be an integral part of it, coordinate with other departments. In the discussion of this matter he called attention to the fact that no other type of medical school has existed on the continent of Europe other than that which was under the fostering care and which shared the ideals of the university. It was under similar ideals that the medical school in this country began, and Dr. Welch traced with admirable clearness the story of the transfer of medical education from the university to the proprietary medical school.

He called attention to the fact that the proprietary school in higher education is a unique institution in the history of education, one for which the United States of America is alone responsible. Dr. Welch traced then in the most interesting way the gradual recovery of medical education in this country during the last fifty years and showed that our medical education is to-day on the up-grade and that we are striving to remove it from the proprietary status and to bring it back once more into a close association with the university, where it may receive both the inspiration and the assistance which it must receive if it is to exist on a true basis.

Since the delivery of Dr. Welch's address two years ago, the Carnegie Foundation for the Advancement of Teaching, in conjunction with various medical bodies which are interested in this matter, has made a careful study of the present status of medical education in the United States and Canada. In the course of that examination every medical school in these two countries has been visited and studied. This includes the schools of every sect of medical practitioners. The material which this study has afforded is now being put into form for publication, and it is hoped that within two or three months it may be given to the public. To-day I shall endeavor to give some general results of that study and to give them in the light of the summary which I have just made from Dr. Welch, that is to say, in full recognition of the fact that the home of the medical school is in the university and that the gains which are to be had by the incorporation of the medical school as a part of the university are mutual, the university on the one hand offering a strong faculty and the medical school on the other hand conferring prestige and honor and scientific enthusiasm on the university. Such union must always be reciprocal if it is to be a true union; and there is no reason for the existence of the medical school in the university unless the university itself both confers and receives intellectual and educational help.

* Read at the Joint Conference of the Council on Medical Education and Committee on Medical Legislation of the American Medical Association, Chicago, Feb. 28-March 2, 1910.

[1] THE JOURNAL, Jan. 4, 1908, p. 1.

A brief statement of the situation which one actually finds in the United States and Canada to-day shows that there are in existence about one hundred and fifty medical schools. We have, in a word, more schools for the training of physicians and surgeons in the United States than are to be found on the whole continent of Europe. Of these, eighty-two are connected with actual colleges or universities. In making this count I leave out of consideration as university medical schools those under the control of such institutions as the University of Buffalo, the University of Maryland, and the like, in which the university is really fictitious. During the last ten years these one hundred and fifty medical schools have graduated on the average about five thousand physicians annually. How great an overproduction of physicians this is may be appreciated from a consideration of the following facts: From the experience in the older countries it seems clear that in large towns one physician for every 2,000 persons would, under present hygienic conditions, be sufficient. In more thinly settled regions one physician for every 1,000 inhabitants would suffice. In general, we may say that one physician for every 1,500 persons would be a fair ratio, and this is approximately that of the older countries of Europe. The actual proportion in the United States at this moment is one physician for every 568 persons, which gives us twice as many physicians per thousand of population as England, four times as many as France, five times as many as Germany.

Consider it again from another point of view. The twelve southern states gained, in 1908, 358,837 persons. On the basis of one physician for every 1,500 inhabitants the section needed, in 1908, 238 more physicians. During the course of the same year there were 465 vacancies due to death. In view of the current overcrowding, these vacancies did not really need to be filled; but if we fill two vacancies with one new physician, 233 more graduates would have been needed; in all, 471 new men. As a matter of fact, 1,144 physicians were graduated in southern schools and 78 more southerners in Baltimore and Philadelphia. The total would certainly come to 1,300 additional physicians, three times what was needed on a most liberal estimate. In the rest of the country the total gain in population was 975,000, to meet which 650 physicians would have been required. There were also 1,605 vacancies by death, to meet which would have required 800 more on the hypothesis just made. About 1,500 physicians would then amply have sufficed to fill the vacancies. As a matter of fact, 3,500 were produced. It seems clear that by the operation of the great number of medical schools and the laxity of our laws we have for twenty years past graduated into the profession about three times as many men as are actually needed.

Before considering the duty of the university in the face of these conditions I wish to refer to one or two of the grounds on which this overproduction has been defended and which, from the material which has been gathered recently, are clearly shown to be untenable. In the inquiries which have been made concerning the reasons for the existence of various low-grade medical schools I have been met everywhere by the statement that it was the function of such a school to furnish doctors for rural regions. It was admitted that the training of these doctors was poor, but the constant assertion is made that the inhabitant of a small village or the resident on an isolated farm must accept this poor medical attendance or none at all. The investigations which we have made show conclusively that there is no truth whatsoever in this claim. It is perfectly clear from the statistics which have been brought together that a low basis of education does not force a distribution beyond a certain point. It may not be generally appreciated that the reverse of this is also true, namely, that a high basis of education does not prevent a wide distribution; that is to say, men graduated from good schools will go into all fields. The fact is that in the distribution of physicians many elements will count—the number available for distribution, home ties, individual tastes, professional opportunity, and financial consideration. The experience of foreign nations and our own shows that more expensively trained doctors will go into the country just as the poorly trained do, and it shows, on the other hand, that the ill-trained and poorly equipped men will in large measure congregate and get in each other's way. In proof of this statement it may be said that in Canada, whose laws for the admission to practice are far more advanced than ours, the well-trained graduates of McGill and of Toronto go in large numbers into the territories of the Northwest. In our own country the most expensive physicians whom we have yet graduated are Johns Hopkins men, and no one would propose to-day that the Johns Hopkins standards of admission and of facilities should be universally enforced. Nevertheless, these elaborately trained men have an astonishing disposition to scatter. They are to be found in thirty-two states and territories, and about a dozen have gone as missionaries to the Orient. One finds a Johns Hopkins man at Clayton, Ala., a town of 1,000; at Gorham, Colo., a town of 364; at Wells River, Vt., with 666; at Fairfax, Va., with 200; at Mazomanie, Wis., with 900. Western Reserve University is almost equally high in its entrance requirements, and one finds Western Reserve graduates in small towns of 700, 500 and 400 inhabitants. The argument that a cheap medical school must be maintained for the benefit of rural regions is absolutely without foundation.

A second argument which has been advanced wherever the low-grade medical school takes root is the time-worn argument on behalf of the poor boy. For example, in the city of Philadelphia, where medical facilities are offered on easy terms and under the most moderate conditions of entrance requirement, Temple University considered it necessary, for the sake of the poor boy, to maintain a night school of medicine. This argument, like the other, is based not on consideration for the poor boy, still less on consideration for the public, but on the desire to run a medical school. The truth is that the medical education which the poor boy thus gets costs him just as much as he would pay for something better. A four-year medical education in the Chicago, Baltimore, or Philadelphia schools on the ordinary basis costs in tuition fees and board $1,370. The same student can go to Ann Arbor for six years and save a few dollars; or if he wants a larger city, to the University of Minnesota at Minneapolis, for a little more. Now the absurdity is here: The low-grade medical school will tell you that their graduates can afford to go to small towns because they have not had an expensive education; well, then, so can the graduates of Ann Arbor and Minneapolis, for their education, though of higher grade, has been just as cheap. In a community where a fairly strong medical school is conducted it is possible to start a new school only by lowering standards, and it is this process which brings in the argument of the poor boy. The truth is that the poor boy has no right to enter the profession unless he is ready to make the sacrifices necessary for the right preparation. It is also true that in any large American community the poor boy who will qualify himself rightly will find the way both to a fitting education and to an efficient medical training. The argument for the poor boy is in effect an argument for the poor medical school, and it has no reasonable foundation.

Taking the situation of medical education as it now stands, knowing, as we now know, how great an overproduction of physicians we have been making, the question to which I wish to bring attention is this: What is the duty of a university with respect to medical education under such circumstances? Granting, as one does freely, that the historic, natural home of the medical school is in a university, what is the duty of an institution toward the teaching of medicine in view of the present situation of medical education and of medical practice in America?

To answer this question fairly, one needs to consider with some detail what the concrete services are which a university can render to its medical school. In seeking to answer that question, one will keep in mind the fact that, while medicine has always been a learned profession, it is to-day true that there is a vast difference between the scientifically trained physician and the able practitioner of earlier days. Within twenty-five years the development of certain fundamental sciences has been so great that the practice of medicine has come to be almost the application of these sciences—or at least this much may be said: the practice must start and rest as it did not in the preceding days on these fundamental sciences—pathology, anatomy, physiology, physiologic chemistry, bacteriology, and the like. This means that to-day we seek to train in our medical schools, as always, the practitioner of medicine, but the practitioner of medicine to-day is a scientifically trained man as he never was before. It does not mean that the analysis of the chemical laboratory or of the biologic laboratory will ever replace the skill of the clinician. It will always be true, so far as we can see, that in the treatment of diseases clinical skill and experience will be the largest factor in the physician's equipment, but it does mean that clinical skill to-day is supplemented with aids which the generation before did not know, and that the practitioner who is trained in a school which is unable to give these fundamental facilities is practicing the profession of a generation ago.

In view of the fact that the clinician is still the guiding spirit in medical education, it will always remain true that a medical school must be made up of school, hospital, and dispensary, operated as a single working plant.

Taking into account the present status, therefore, of medical education and taking into account also the standards of training which modern practice demands, it seems to me that the concrete services which the university can render to its medical department may be grouped under three heads:

1. The definition and maintenance of entrance standards.
2. The inspiration of the medical school with an appreciation of productive ideals both in education and in science.
3. The financial support of the medical department exactly on the same basis as other departments are supported.

To put the matter in a single sentence, a university which understands the present situation in medicine, which appreciates the ideals of modern medicine and which appreciates as well its own duties and responsibilities, will make itself responsible for the standard of admission to its medical school, for the ideals which govern it, and for the financial support which is to maintain it.

What is a reasonable basis, what is a reasonable standard to exact as the basis of a medical education? It is generally conceded that a scientific training in physics, chemistry, and biology constitutes an almost indispensable preliminary qualification for the study of medicine. As our present educational system stands, it is practically impossible for the student to obtain this equipment short of two years of college study, which would mean his entrance into the medical school at approximately twenty years of age.

When one comes to consider the enforcement of such a standard, however, it is clear that one must take into account the status of educational facilities in the various sections of the country. No standard can be enforced for which the schools and colleges of the region cannot reasonably well fit students. Our present educational facilities in the eastern and middle states and in the western states are already so considerable, they are so rapidly increasing, and they respond so quickly to pressure of the right kind that there is no question that the requisite number of physicians could be obtained from these sections even with the enforcement of such a standard as that indicated. The only practical difficulty that stands in the way is that the enforcement of such a standard would involve the death of most of the medical schools now existing in these regions.

In the South matters are very different. Both the legislative conditions and the educational facilities in that region are such that the standard just proposed, which is clearly a fair one for the profession itself, could not possibly at this moment be suddenly applied. This, however, is no excuse whatsoever for the almost utter absence of standards which is characteristic of that section. Only three complete institutions in the twelve Southern states have anything that can be definitely called a standard of admission for their medical schools. These are Tulane, the University of Texas, and the University of Virginia. Inasmuch as standards in medical education are necessarily tied up with the general educational system, I venture to suggest that the feasible standard in the Southern states at this moment for entrance into the medical schools is the same as that for entrance to the academic department, that is to say, high school preparation. This is the level which the general school situation of the different states either reaches at this moment or will reach in the near future. From this point progress may be gradual, but it will be inevitable. I venture to point out also that the enforcement of even this standard in the South will bring about the extinction of most existing superfluous schools.

One more thing I venture to add concerning the matter of standards of admission to the medical school, a statement clearly applicable, however, to the American university throughout all its courses, and that is that no increase of standards is helpful which does not mean actual enforcement. The conscientious and just enforcement of the four-year high-school standard throughout the whole country would alone go far toward clearing the situation; but in any case a university which undertakes to maintain a medical school ought clearly to face the duty of maintaining in its medical school standards fully abreast of the educational status of its region. If an institution is not willing to do this, then it ought not to meddle with medical education at all. The college or the university which maintains a decent standard of admission for its college and a far lower one for admission to its medical school is frankly disregarding its own duty to medical education and is seeking, as a rule, to support a medical school out of fees in order to have a certain institutional completeness. The day has gone by in the United States when an institution calling itself a university can do this without being recognized as shirking the responsibilities of a true university.

There are in the United States a few institutions of high grade which require college graduation for admission to their medical schools. We may rejoice to have this standard set up in a few of our best schools. I do not believe, however, that it will be generally adopted, and largely for the reason that, however necessary it is to give the medical practitioner the advantage of a liberal education, it is also important for him to get into the profession before he is too old.

With regard to the second specific service of the university to the medical school, namely, as to its influence on the pedagogic methods and the scientific ideals, I venture at this point merely to call attention to the very general neglect of this function of the university in most American institutions. The American medical school, even when it has been incorporated into the university itself, has remained in many cases an *imperium in imperio*. There has been, as a rule, little commerce between the professors of medicine and the professors of other faculties of the university. This has been due in part to the fact that the professor of the medical school has been in the past a practicing physician coming into the school for only brief lecture hours and having little touch with teaching or with the members of other faculties. In the best schools to-day, where not only the professors of physiology, pathology, chemistry, anatomy, and biology are men giving their whole time to the work, but where also the professors of medicine, of surgery, of pediatrics, are coming to be placed on an explicit teaching basis, the opportunity for the development of a true university spirit in the medical school is beginning to appear. This ought to result in the spread of the scientific spirit through the medical school; and while it will always remain true that the chief function of the medical school is to train the medical practitioner, it will also be true that the spread of university ideals will mean that more men will take up the investigation of medical problems from the scientific standpoint and that our medical schools, so organized, will lend themselves in increasing measure to the development of the scientific side of medicine and the investigation of its problems.

I venture here to allude to one feature of our American medical school organization which, from the standpoint of one long associated with an institution of learning has struck my attention forcibly, and that is the project for a divided medical school. It seems clear to me that such a school has distinct disadvantages and that the very division gives up in large measure the opportunity of the university to create in the medical school university ideals. It is difficult to understand, for example, how a medical school in which the clinical school is two hundred miles away from the scientific laboratories can receive any great inspiration from the men who work in these laboratories. Still more difficult must it be for the clinician, whose spirit ought to dominate the whole institution, to keep the laboratory methods and the laboratory men in touch with clinical aspirations and clinical needs. It may be that the divided medical school will succeed, but it seems that it must succeed against much greater obstacles than the school which is organically one. I cannot help wondering, for example, how it would affect the pedagogic and professional ideals of an engineering school if the first two years of it were given in one place and the last two years in a place two hundred miles away. My impression is that there would be two separate schools with very little more reaction, the one on the other, than exists between any other two schools so situated.

With respect to the third service which the university ought to render to its medical department, namely, that of an adequate financial support, I wish to speak with some degree of definiteness. This obligation is one which few colleges or universities in our country have frankly faced. In more than one report of university presidents during the past year I have read the boast that the medical school has not cost the university a cent! Colleges and universities have taken over medical schools in distant places with no expectation whatsoever of furnishing any support, and generally throughout the relations which have existed between colleges and universities on the one side and medical schools on the other there has been a most remarkable absence of any sense of financial obligation on the part of the university. I am convinced that this action has been due in the main to a lack of knowledge on the part of college and university trustees and officers. They have come to look on medical education as self-supporting; they desire a medical school in order that their institution may seem complete. The overproduction of physicians is a matter with which they are not acquainted, and the college and university have gone ahead to take over a medical school with absolutely no thought of its support—a thing which they would never do with a school of applied science. Just why it should be believed that a medical school could be sustained by moderate fees, while an engineering school or a college of arts needs a large and strong endowment, is a matter which I have found it difficult to understand. Furthermore, when an engineering school undertakes to sustain itself in the main from fees, it exacts a fee somewhere comparable with the cost of the education. Thus the Institute of Technology at Boston, which is sustained in the main from its fees, charges a tuition fee of $250 a year and laboratory fees in addition, which amount in some cases to $50 more. Such a fee for a medical department would be thought impossible.

What does it cost to run an adequate, all-round medical school? By an all-round medical school I mean one in which all departments are fairly strong. It will be found that some schools of fairly high reputation have maintained themselves by making a single department strong and leaving all the rest weak.

The investigations of the Carnegie Foundation prove that it costs easily $10,000 a year to conduct any one scientific department of the first two years of medical education in a satisfactory fashion for classes of fair size. This means the teaching of a comparatively small number of students and makes relatively slight provision for any scientific activity on the part of the teachers. A number of institutions that are economically conducted spend $15,000 or more a year on a single subject like pathology or physiology, including a fair provision for investigation, and these are not institutions which one would think of as most liberally endowed. A medical school, therefore, which is not in a position to spend $50,000 or $60,000 a year on the work of its first two years has omitted some part of its legitimate duty. It will be difficult for any complete medical school to do its fair duty by a moderate body of students with an income of less than $100,000 a year. Furthermore, this cost will increase rather than diminish, for the reason that with the improvement in the training of the first two years correspondingly improved clinical teaching will be required. It has been one of the anomalies of this whole development to note that many medical schools have acted on the idea that standards of admission could be raised without further provision for an improvement in the teaching facilities and in the teaching itself. It requires only a year's experience, however, for such a school to appreciate the fact that young men who have had two years of college training will not be satisfied with the kind of teaching nor with the facilities which will be accepted by boys fresh from the high school. The college trained man becomes restless under the physician who drops in to lecture and spends half the time in telling stories from his medical practice, and he is not at all willing to sit under a teacher whose knowledge of his subject is evidently gathered from the text-book before him. The raising of standards of admission means an important increase in expense on account of the quality of the instruction. An institution which undertakes the teaching of medicine on a basis much lower than that which I have indicated is not likely to serve either the cause of education or the cause of medical practice, and an institution which finds itself facing the question of the creation of a medical school or of the adoption of one should fairly face also the question whether it can get the means necessary for its support. It goes without saying that no university is justified in entering into any arrangement for a medical school which rests on a contractual relation. Unless the university can control, inspire, and support the medical school, it has no right to it.

Few institutions in the United States or Canada have lived up to their obligations to their medical departments in all three of the essential respects to which I have referred. Some have not even appreciated any one of them. As I have before remarked, eighty-two of the one hundred and fifty medical schools of the country are connected with actual colleges and universities. Of these, perhaps one-half fulfil all three of these obligations in a reasonable degree, in the sense that the universities fix and enforce definite standards for entrance, secure the same sort of teaching and scientific activity in the medical department as in others, and, finally, make themselves responsible for funds that go far beyond tuition fees received by the medical department. Of these institutions it may be fairly said that they are alive to and meet the responsibilities which they have undertaken in the matter of medical education.

There is in the next place a group of medical schools legally and organically parts of a college or university, but neglected by the institutions of which they are a part in one or more of the three services to which I have referred. It is difficult to say what these departments gain by their university connection. They receive no support, they get no oversight, they do not breathe the university air, nor receive any inspiration from university ideals. For example, the medical departments of Vanderbilt, Northwestern, Tufts, Bowdoin, administer in their own way the entrance requirements which the university sets up, and in none of these cases are the entrance requirements strictly enforced. In the matter of support, the university is often a harsh creditor to its medical department, sometimes not even lending it a dollar and at other times exacting, as in the case of Vanderbilt and Tufts, principal and interest for every advance made out of the general funds. As these institutions, organic university departments though they be, live on their fees or less than their total fee income, it is clear that the ideals of the university do not materially affect them. They are for the most part routine teaching schools, in no true sense university schools. Some of these organic medical departments belong to universities which can hardly hope by anything short of a miracle to do anything for medical education. For example, Drake University, with total productive funds of $290,000, has an organic medical department. The University of Alabama, with a total state appropriation for buildings and maintenance of $71,000 a year, has such a department. So have the University of Mississippi with similar appropriations of $110,000, the University of North Carolina with an annual appropriation of $70,000, the University of Tennessee with an annual maintenance appropriation of $65,000. It is perfectly clear that the problem of medical education is begun rather than solved when a university incorporates into its organization a medical school.

Twenty-seven of the remaining colleges and universities of the United States and Canada have nominal or affiliated medical departments which they not only do not support, but do not control. The state universities of Arkansas, Georgia, Illinois, and Oregon are in this position. Among endowed institutions that lend their names to proprietary medical schools for which they can hope to do nothing and which they do not control so long as they are in this situation are the University of Denver, Washburn College, Cotner University, Ohio Wesleyan University, Epworth University, Baylor University, and Dalhousie University. The budgets of some of these institutions are absurdly small in comparison with the cost of a decent medical school. Among them are some which are capable of leading respectable lives as colleges, but are little less than impossible as universities—for example, Union University, New York, which is the name given to the superficial combination of Union College with weak schools of law and medicine in Albany.

In a word, an inspection of the eighty-two medical colleges in the United States and Canada which are associated with colleges and universities shows that the relation is in many cases a superficial one. The college or the university has not in these instances approached the problem of medical education with serious purpose or with any fair sense of its responsibilities. It has been willing to give its name to a medical school, no matter how far away it was from university ideals and scientific traditions. In truth, the colleges are in no position to throw stones at proprietary medical schools.

of cases. A close analysis of the latter cases would undoubtedly raise the percentage of positive reactions, as too frequently the clinical diagnosis, which is often accepted when the serum reaction is negative, is incorrect.

The results obtained by various investigators during the primary stage vary. This in all probability is due to the different periods with regard to their infection in which they were examined. Some report finding the reaction in two-thirds of the cases in the chancre stage, others as high as 90 per cent., and my own results run as high as 100 per cent.

Bruck, Stern and Lesser report finding the reaction in a few cases before the appearance of the initial lesion. Lesser obtained the reaction for syphilis in a case of gonorrhea one week following exposure, whereas the chancre did not appear for two weeks, which, in turn, was followed in six weeks by secondaries. The results obtained in the primary stage are of great importance when we consider the possibility of prophylaxis against general infection by extirpating or destroying the initial lesion. It would appear from the observations of many that the reaction does not appear as soon as the initial sclerosis, but a few days or a few weeks later. On the other hand, the reaction has been found positive before the lesion has appeared.

TREATMENT

While I am disinclined to believe that the extirpation of the initial lesion, a teaching centuries old, will obviate the occurrence of a systemic infection, it would seem consistent with our present knowledge of the question that, if a local genital or extragenital lesion contained the *Spirochæta pallida* (which is regarded as the cause of syphilis), and the blood serum was negative to the syphilitic reaction and there was no evident adenopathy, the chancre should be removed. I would not expect this to obviate the general infection, because we know from clinical experience and from reports of cases so treated that it does not do so, but if the primary infection is a local one and the constitutional infection is not detectable at the time of blood examination, this would appear a tenable procedure.

In order that the serum reaction for syphilis may prove of value as an index to specific treatment, it is necessary to know whether or not its occurrence coincides with the activity of the virus, whether with the subsidence of the latter, viewed from a disappearance of symptoms, the reaction becomes weaker, and finally negative, and whether a positive reaction during apparent latent syphilis is, in the absence of visible or palpable specific lesions, to be regarded as a forerunner of them, or indicative of visceral luetic changes. The obtaining of a positive reaction in secondary and tertiary cases to the extent of from 90 to 100 per cent. is conclusive evidence of its association with virus activity.

In nearly all patients placed under vigorous antisyphilitic treatment a weakening and final disappearance of the reaction will follow. The reaction rarely disappears before the symptoms, and usually not for some time thereafter. Some tertiary cases that seem resistant to treatment continue to show the reaction and form an exception to the above rule. But this is, in all probability, due to the fact that many of these individuals are more or less immune to specific treatment and the process continues active. The frequency of the reaction in the early periods of latency in syphilis, where it is not treated, is, from a clinical standpoint, comparable to the frequency of recurrences in these cases. Its occurrence in later periods of latency is likewise comparable to the frequency of visceral lesions found in old syphilitic cases that come to post-mortem from other causes and are there recognized for the first time, and to the development of many visceral and parasyphilitic lesions recognized during life.

The following facts, first, that the reaction is found in practically all secondary cases and in 90 to 95 per cent. of tertiary cases; second, that the reaction weakens and finally disappears; as do the symptoms under specific treatment; third, that a negative reaction and absence of symptoms may sooner or later be followed by a reappearance of both, seem to me incontestable evidence that the reaction means, when found, active syphilis, and is therefore a positive indication for treatment.

If an individual who has been apparently free from symptoms and in good health for years gives a positive serum reaction, it signifies that he has somewhere in his organism an active syphilitic process. This may be in a location that does not cause symptoms and is not ascertainable by the physician. It may signify the development of a serious visceral or parasyphilitic affection, for we know that in practically 100 per cent. of cases of general paresis and in a very large proportion of tabes the serum reaction is positive.

As the treatment for syphilis is usually continued for from one to three years, the serum reaction could be of value only during this time in deciding whether or not the treatment is being pushed to the necessary extent, but in no case should it be interrupted unless the patient gives a negative reaction.

As it is a matter of experience that during the periods of latency the serum reaction is found positive in a considerable percentage of cases, which concurs with clinical experience that recurrences are not infrequent during this time, patients should be controlled at comparatively short periods with the serum test as well as by clinical observations. This should be done because, while the manifestations, if they appear externally, might be considered a sufficient guide for resumption of treatment, no one would care to await a recurrence in the form of a specific meningitis when we have a means of ascertaining activity of syphilis and of anticipating such a catastrophe.

On the other hand, when treatment is given a patient each year or oftener, such frequent examinations might not be necessary, but no period of treatment can be considered complete in the light of our present knowledge unless it is controlled by the serum reaction; so that not only is it an index to the beginning of treatment, but also to its interruption. It should be borne in mind that the skin and mucosa manifestations of syphilis are the least important in the life history of a syphilitic patient, and that patients are not safe because such evidences have not appeared for years. Such lesions seldom prove dangerous to life; at the same time we know that, next to tuberculosis, syphilis, directly and indirectly, is the most frequent cause of death in man (Gerhardt). Its fatal action is through the cerebrospinal and cardiovascular systems, glandular organs, etc.

Patients should never be assured that they can be or have been cured of syphilis, for once syphilitic always syphilitic. The continuous treatment of the first three or four years following infection should be followed by the chronic, intermittent treatment. No period of treatment should be interrupted unless the serum reaction is negative. No patient should be allowed to go longer than three months following the chronic, intermittent treatments in the earlier years, nor longer than six months in later years without a serum test being made. By this method many of the serious and fatal consequences of syphilis will be obviated.

CONTAGIOUSNESS AND MATRIMONY

No opportunity for observations on the question of contagiousness appears to have come to those who have reported on the serum reaction. It is evident that no opinion on this point, so far as it concerns the serum reaction, could be expressed. It is equally evident that any solution of the question of matrimony for a syphilitic based on this reaction could be arrived at only by a study of the question of contagiousness, which is impractical. Any regulation of matrimony on this test alone would seem to be unfounded. However, after the period of time which clinically has been regarded as necessary to elapse before a syphilitic is considered safe to marry, his blood should be negative to the serum test, and the same injunctions for controlling his case as outlined above would be advisable.

PROTECTING THE INDIVIDUAL

The serum reaction is found positive in practically all cases of general paresis, and in a large percentage of tabes cases. While the percentage of positive reactions in tabes cases varies more or less, as reported by various investigators, this is perfectly conceivable when we remember the chronicity of tabes and also the frequency with which tabetics have been subjected to specific treatment, as a result of which abeyance of the virus activity may occur, but at the same time the pathologic changes of tabes continue to progress. We also know from clinical experience that chronic infections may have periods of quiescence irrespective of treatment.

Many visceral lesions of syphilis are first recognized post-mortem, and, as a matter of fact, fully half the syphilitics that come to post-mortem from other causes show some evidence of syphilis that was not recognized during life. Fully 50 per cent. of latent cases of syphilis give positive reactions. There can be little doubt that this is more than a coincidence, and that there is a direct association of the latter with the former post-morten facts. This, as well as the previous mentioned relation of the reaction to syphilitic manifestations, its failure with their disappearance and the return of both, all indicate that a positive reaction indicates activity of the virus. Recognizing this, it seems perfectly logical that we should expect to obviate many of these latter developments of syphilis by controlling the patient's condition with the serum reaction and medicating accordingly.

REACTION IN HEREDITARY AND CONGENITAL SYPHILIS

In hereditary syphilis the test is found, I may say, constantly, the reaction is strong and appears slow to disappear under treatment, possibly because the latter is not continued long enough, as is too frequently the case in congenital syphilis. Many workers who have reported on this phase of the question claim a concurrence of the reaction with the Colle and Profeta laws, while others maintain a directly opposite view, contending that neither law is sustained in the light of this test.

I have examined the blood of women who have borne syphilitic children, and who themselves were clinically apparently free from the disease, and the reaction was negative with their serums. I have also examined a syphilitic woman who had borne a healthy child who had not given the reaction up to the sixth week. On the other hand, the blood of a six-months-old infant born of a tertiary syphilitic mother gave a positive reaction, although this infant had never, so far as the history and examination could be depended on, presented any evidence of syphilis.

3220 Jackson Boulevard.

STATUS AND DUTY OF THE MEDICAL OFFICER *

LLEWELLYN B. ASHTON, M.D., C.M.; PHM.B. (TOR)
Lieutenant, Passed Assistant Surgeon, Illinois Naval Reserve
QUINCY, ILL.

The history of the military surgeon is the history of surgery, for he has always contributed freely of the knowledge gathered in the great school of the battlefield to his less fortunate brothers in civil life, the evolution of his handicraft keeping pace with the growth of medico-military lore. In the early days he was much less favored in academic accomplishments than now; in fact, there was a marked difference between the social standing of the surgeon and that of the physician of that time, for, while the latter was scholarly and refined, and usually succeeded in maintaining his caste, the surgeon was of lowly origin and followed a despised calling. In the dark ages surgeons were little more than body servants to the generals and officers commanding—often serving in the double capacity of surgeons and barbers. Needless to say, the skill and the numbers of such men were insufficient for the task of treating the sick properly; indeed, the common soldier of the early period was given but scant consideration in any event, for it is said that Xenophon had but eight surgeons with his ten thousand troops.

Throughout the middle ages, military surgeons were still inconspicuous for any good purpose they served; they had no regular place in the ranks nor did their names appear on the pay rolls; they took such compensation as they received in gifts from grateful patrons. Out of the stormy centuries of the middle ages, when the profession of arms was occupying the first place in human endeavor, grew a greater appreciation of the need of organized effort to minister to the sick and wounded while bearing arms. Naturally the French and English were the most active in this attempt, and we find Ambroise Paré in the sixteenth century, and later Percy and Larrey, under Napoleon, exercising a marked influence on the practice of the day, for they were men of strong and resourceful personality.

The eighteenth century was well advanced, however, before any of the customs which obtain to-day were instituted, for, in Great Britain, it was not until 1751 that surgeons were uniformed in the dress of the troops with which they enlisted. The physical examination of recruits was begun in 1745. Coming down to the last century, the German sanitary corps was made a part of the German army as late as 1873. In 1860 the first British army medical school was opened at Chatham, since which time the modern army surgeon may be said to have developed. In 1878 the British Royal Army Medical Corps was formed.

In the United States, the early army medical records repeat the stories of the European wars—splendid achievements of individual surgeons of marked genius, but little concerted action on going into battle, and none when on a peace footing. Means of caring for the sick and wounded on the battle field and in camp long have been sadly inadequate, and improvements always have been greatly hampered by a want of proper understanding of the immutable laws of sanitary science and cooperation therein by officers of the staff and line. Until a year or so ago the young cadet at West Point was taught more of the care and health of the horse than he was of

---

* Read at a meeting of The Fifth Infantry, and Naval Reserve Officers' Association, at Quincy, Ill., Dec. 8, 1909, and before the Adams County Branch of the Illinois State Medical Society, at Quincy, Dec. 13, 1909.

that of the men whom he was destined to command; in other words, he was so intent on studying how to destroy the enemy that he gave no thought to saving himself from destruction by deadly internal foes. Naturally the sick soldier always has been a great impediment to the movements of the army corps, and it was never even suspected until a few years ago that most of the camp sicknesses were preventable.

It also may be said of the military operations which have been conducted by the United States more recently that a grievous failure to grasp the true relation of the medical department to the army as a whole has no doubt cost the lives of many thousands of our bravest and best citizens; for it is estimated that, in most of the campaigns of the past, more men have been killed or incapacitated by disease than by the bullets of the enemy.

What, then, is the status and duty of this organization of specially trained men who fight under the banner of the Red Cross? For, whether they enlist with the organized militia, the army, the navy, or the Army Reserve Medical Corps, their function is the same; first, the preservation of the health of the command by the prevention of disease, and, second, the prompt restoration to duty of all wounded men whose disabilities admit of a cure. Since, as already stated, more men are cut down by disease than by bullets, the first of these duties is the greater; and this fact is emphasized by the statistics gathered at the concentration camps of the United States forces during the few months that they were ordered South in 1898, where men were allowed to sicken and die who never heard the sound of battle, save perhaps in their delirium. By comparing these recent events in a modern army, composed of the flower of American youth and having every facility for care at hand, with the experiences of the Japanese army while operating against the Russians for nearly two years in a wild and foreign land, destitute of bases of supplies for the barest necessities, we find a very creditable showing for the Japanese, remarkable for its low sick-rate. The reason is that to-day no other country holds its military surgeons in such esteem and respect. This nation, just emerging from a medieval civilization, has been quick to profit by the mistakes that the western world has only gone on repeating. The Japanese called into service a scientific body of medical men and followed implicitly the suggestions of these expert sanitarians; camp sites, food, water, shoes, clothing, the personal habits of the men, their preparation for battle—every detail of the organic life of these troops was passed on by their medical department, and that untrammeled by official influence or political despotism. Its ruling was paramount—the last word on sanitation.

The scientific awakening of the last two decades and the application of the principles of sanitation to commercial and industrial life are in evidence on every hand. Large employers and manufacturers now consider it good business policy to conserve the health and energy of their operators as a factor in a larger output from their labors. So, too, this nation when it took over the reconstruction of an oppressed people in Cuba, at once found it necessary to engage in sanitary, as well as political government. Our national problems in these piping days of peace have been met more effectually than they could have been in the earlier days when our interests were less world-wide, and knowledge less complete. The addition of the Philippines, Porto Rico, the Canal Zone in Panama, and other tropical possessions has thrown a greater responsibility than ever on our military surgeons, the sanitary engineers of this country. These great responsibilities have made necessary the manning of garrisons and ships of the United States with men unaccustomed to life in the tropics, and in the successful accomplishment of this end the medical departments of all arms of the service have been ever in the vanguard, so that now these territories have been rendered habitable for troops and increasingly healthful for the natives.

General Leonard Wood, who cleaned that pest-hole, Havana, of yellow fever in less than one year, was first a well-trained physician. Drs. Reed, Carroll, Lazear and others, who, by their experiments on the nature and mode of infection of this disease, made it possible to accomplish such a miracle, were also U. S. Army officers. Col. William C. Gorgas, chief sanitary officer of the Isthmian Canal Zone, another U. S. Army surgeon, profiting by his earlier experience in Cuba, has solved the riddle of the Panama Canal, converting a death-trap and slough of despond into a veritable health resort; and thus the dream of adventurers, navigators and engineers at last is coming true. The death-rate of 176.97 per thousand, under de Lesseps, in 1885, now has fallen to 3.84 per thousand among its male white population, under the direction and control of the United States, since the venomous mosquito has been banished.

It is also interesting to note the vast amount of human endeavor that has been contributed to the public weal by the military medical officer in foreign lands, for Science truly knows no country, and to the military surgeon,

"In all lands and thro' all human story
The path of duty is the path of glory."

As an evidence of this fact we may recall that the first observation of the parasitic organism of malaria in the blood of malarial patients was made by a surgeon of the French army, Laveran, who worked it out in the solitude of a military hospital in far-away Algeria in 1880; although the U. S. Army Reports of 1859 show that in that year an American medical officer, John K. Barnes, had called attention to the probability that this disease was of parasitic origin. The knowledge that the mosquito is the medium of infection in malaria is of still more recent date, and this we owe to an English army surgeon, Major Ronald Ross, whose discovery has saved thousands in India alone, since he announced his theory in 1897. Another of this brave band of grim fighters of the invisible was Bruce, who, while serving the British Empire as patriot and scientist, rid the Island of Malta of Malta fever, a pestilence which had scourged it since before the days when it sheltered that gallant company of Hospitallers, the Knights of Malta.

In an address on "The Nation and the Tropics," given at the London School of Tropical Medicine in October last, Dr. William Osler so fitly has eulogized one of the leaders of these forces, "one that sought but Duty's iron crown," so fittingly that I cannot refrain from quoting the passage entire. He says:

> No one has expressed more deeply the sentiment of lonely isolation in the tropics than Ronald Ross in his poem, "In Exile:"
>
> "Long, long the barren years;
> Long, long, O God, hast thou
> Appointed for our tears
> This term of exile."
>
> Few have been able to sing with him the pæan of victory when he discovered the mode of dissemination of malaria through the mosquito—
>
> "Seeking His secret deeds
> With tears and toiling breath
> I find thy cunning seeds
> O million-murdering death."

And the pathway of victory is strewn with the bodies of men who have cheerfully laid down their lives in the search for the secrets of these deadly diseases—true martyrs to science.

What is true of the prevention of epidemic diseases which have proved decimating to troops stationed in the tropics should be equally true of typhoid fever and other camp diseases peculiar to more temperate latitudes. In the experiments carried on in the English and German armies, and on the U. S. troops now serving in Porto Rico, it has been shown that the immunity acquired by serum vaccination of men exposed to typhoid fever has decreased the sick-rate from this disease from 12 to 3 per thousand. Lord Kitchener has recently said that the improvement in the condition of the British army in India during the last ten years has been equivalent to adding more than another regiment to its strength. "In pace paratus" should ever be the watchword.

The military and political destiny of the great nations of the world is intimately bound up with the progress of medical science; for the appreciation by their people of the natural and physical laws which govern the most economical maintenance of armed forces in the event of war will keep step ever with the march of the latest scientific achievements that have any bearing on maintaining the fitness and efficiency of the individual soldier. On this will follow a fuller control and authority in all sanitary measures by the medical officer, the logical military sanitarian.

How, then, may this standard best be attained? In the national guard and naval reserve organizations we have our limitations in time of peace, by reason of the lack of opportunity for practical work in the short tour of duty in camp and afloat each year; yet in time of war we would constitute the major part of the land and naval forces, and it would be up to us to make good. We, therefore, must look to the regular forces as the working models in this work and be eternally prepared by lending our every effort to the extension of the value of tours of instruction for men, of the time of such instruction, and in the establishing of local schools for study by officers. It is a matter of regret that by reason of their smaller number the volunteer medical officers cannot avail themselves of state, or central professional medical schools for the interchange of ideas.

The needs of the situation could be met by the endowment of chairs of military surgery and sanitation in the leading medical colleges throughout the country, open and free alike to all military officers as well as to undergraduates. A natural channel affording a medium for presenting and discussing all matters germane to the subject of medico-military interests might readily be formed, too, by assigning this branch to some correlated section in the state and national medical societies, where the medical officers among the membership, and those of the army and navy at large, could get together at the annual meeting to their mutual profit and pleasure.

As a result of this activity would follow a growing interest by medical men, both of the organized and unorganized militia—for all are alike eligible for service—and a working knowledge of military medical affairs would soon engage the attention of all medical societies to an extent quite unknown now, and to the lasting good of our military organizations.

Looking toward this end, it might be wise to expand the Section on Preventive Medicine and Public Health of the American Medical Association so as to include at once its public and military phases under the heading of Section on Preventive Medicine, Public Health and Military Sanitation, or some other suitable descriptive title. The British Medical Association already has a Section of Navy, Army and Ambulance.

Perhaps the greatest need in the state militia organizations is that they be provided with improved facilities for maintaining regimental and field hospitals in conformity to the regular types to facilitate the training of ambulance companies; but this equipment is now not easily obtainable, because of the indifferent and penurious support of our legislators and their fatuous confidence in the ability of the American soldier to fight when he is called on, however unprepared. The medical officers should also seek by every opportunity to master the manual on the handling and training of men, besides all those details which administration implies. Unfortunately the civil duties of a surgeon count for little in military experience, other than in the routine treatment of sick-call; but, given an occasion, the trained volunteer surgeon should, and the regular certainly would, be competent to take over all the sanitary departments of troops in the field, assuming full charge in every particular.

Through the rare executive ability of the late Col. Nicholas Senn as Surgeon-General of the State of Illinois work was begun along these lines; for he was an authority on military medical science, having studied at first hand the methods of all the leading armies of the world; and as a result our medical department is now, perhaps, more advanced than that of any other state in the Union. It was through his personal effort that the Association of Military Surgeons of the United States and the Association of Military Surgeons of the State of Illinois were instituted; these have proved of the greatest value to the whole body, bringing into touch the brightest minds in the profession for the study of the serious problems of the organized forces.

The Army Medical School at Washington is thrown open now to volunteer officers of the land forces, admitting them equally with the regular army officers to all of its privileges, and to make it easier for them the preliminary qualifications have been waived in a large measure. A similar arrangement has been recommended by the Navy Department in connection with the Naval Medical School, especially for medical officers of the Naval Reserve; this recommendation is now awaiting the necessary legislative action. Perhaps in no other way could so much real benefit be conferred on the personnel of the state militia as through the helpful associations that these special courses offer. It is a regrettable fact that as yet but few men have availed themselves of this opportunity; possibly by reason of the loss incurred through neglect of business for several months, and the expense incident to the course, for there is now no appropriation providing for quarters and pay in the case of militia officers attending.

In the navy a new mark was set when the executive authority on the hospital ships was transferred from the line to the medical department, an arrangement which now is giving entire satisfaction. Another era will dawn when some of the traditions of the army also have been set aside and a wider advisory sphere of usefulness and responsibility granted the medical department, whereby it may become an integral unit fully manned, with complete control of all subordinates and auxiliaries, working independently and smoothly along with the fighting forces.

On the foundation already laid let us go on building according to the latest scientific attainments, until military life shall be made at least as sanitary and wholesome as the homes that our young men leave when they enter this noble calling.

In this paper I have not sought to present the many specific duties of the medical officer as defined in the regulations, but rather to suggest the larger scope of military hygiene and sanitation, in which the members of the medical department and the officers and enlisted men of the line must labor side by side—for we are, indeed, our brothers' keepers. And, growing out of this harmony and cooperation, coupled with an awakened intelligent public sentiment, will surely blossom the perfection and preservation of an improved physique, morale and effectiveness throughout all branches of the armed forces of this nation.

Eighth and State Streets.

THE ARMY MEDICAL CORPS AS A CAREER

EBEN C. HILL, A.B., M.D.
First Lieutenant Medical Corps, U. S. Army
MADISON BARRACKS, N. Y.

Dr. Osler, in an address[1] before the graduating class of the Army Medical School in 1894, pictured rather clearly the general conception of the life of an army surgeon as held by the medical profession at large. In somewhat varied guises, his attitude is reflected in the advice that is apt to be given when a student of medicine, or a recent graduate, is considering the army as a career.

Also, as will appear, Dr. Osler's words indicate a lack of definite knowledge on the part of general practitioners as to the duties and opportunities of a medical officer. In beginning his address he says:

> For me the Army Medical Department, so far as particulars are concerned, means a library with unsurpassed facilities, the worth of which is doubled by the liberality of its management; a museum in which I have spent some delightful hours; an index-catalogue, which is at my elbow like a dictionary; and the medical history of the late war. . . .

Later, in attempting to cheer the surgeon who is about to enter on a career in which, as Dr. Osler intimates, there will be few cases, little opportunity for contact with medical centers and isolation from professional colleagues, he remarks on the pecuniary advantages and admonishes the beginner that "faithfulness in the day of small things will insensibly widen your powers, correct your faculties and, in moments of despondency, comfort may be derived from a knowledge that some of the best work of the profession has come from men whose clinical field was limited but well tilled." Again, he remarks that "after all, the isolation is neither so enduring nor so corroding as might have befallen your lot in the routine of country practice."

That a physician of such broad knowledge and such keen perceptions should have held these views is not surprising, for few physicians in civil practice have opportunities of observing the medical service at army posts. They argue that, since soldiers must be physically sound on enlistment, there can be comparatively little disease except that of venereal origin. As a result the advantages of the regular and sufficient pay must be balanced against a very narrow professional experience.

This article is not intended to create an impression that the average soldier is an invalid. Nor is it desired to intimate that the army surgeon is constantly holding clinics of peculiarly interesting cases. But by emphasizing the fact that an army post contains not only soldiers but also women and children, and by briefly outlining the manner in which the physicians are selected and trained for the corps, I hope that I may show that the isolation from professional colleagues is not serious, and that the entrance into the medical corps does not signify a future "professional degeneration"—a prophesy I have heard often expressed.

EXAMINATION AND PREPARATION

On entering the medical corps at the present time a physician must pass, with an average of 80 per cent., a preliminary examination usually covering a period of six days. This consists of a physical and professional examination. If successful, the candidate is commissioned as a first lieutenant of the medical reserve corps until his graduation from an eight months' course at the Army Medical School in Washington. During this probation period he receives $2,000 a year, an allowance of $36 a month for quarters, and an ample allowance for fuel and light. At the school excellent courses requiring thorough preparation and diligent attention are given in clinical microscopy and bacteriology, military hygiene, military surgery, military and tropical medicine, sanitary chemistry, operative surgery, ophthalmology and optometry, x-ray work, hospital corps drill, and duties of medical officers, medical department administration and customs of the service. The scope of these courses may be realized when it is mentioned that a recent graduate in medicine who had studied under Professor Ziegler of Freiburg and Professor Welch of this country found no opportunity for reminiscences during the hours devoted to pathology and bacteriology. On graduation the officer is commissioned in the medical corps as a first lieutenant. His pay for the next three years, until his captaincy, remains the same. On changing station, mileage at the rate of 7 cents a mile is allowed, and 5,100 pounds of household effects are crated and delivered to his new post. A leave of thirty days is obtainable each year.

The professional opportunities of the service are not fully appreciated by the profession at large, so it may be permissible to comment on the range of diseases which may be met in this country. In contrast to the rather general impression, venereal cases play quite a subordinate part in the sum total of disease at a post. There is, to be sure, venereal disease, but a routine treatment is usually adopted, and after the diagnosis is assured there is little attention paid to this form of sickness. Records are kept for reference and syphilitic patients are compelled to continue treatment for a definite period after leaving the hospital. Under existing army regulations this is easily possible, whereas in most civil clinics the patients are lost track of after a month or so. Accordingly, even with treatments covering long periods, little time has to be devoted by the surgeon to venereal disease. This is fortunate in that a surgeon has ordinarily many other cases requiring study and thought. When one considers that on an average post there are from 50 to 100 women, counting the wives and relatives and servants of the officers and non-commissioned staff, 25 or more children and usually from 300 to 800 men, it may be seen that a surgeon has a rather varied practice in general medicine, surgery, children's diseases, gynecology, obstetrics and other specialties. Instead of a narrow practice confined to a few cases, it is extremely general.

---

[1] Osler, William: The Army Surgeon, in *Æquanimitas and Other Addresses*, p. 103.

RANGE OF PRACTICE

Reviewing the cases of three months at a certain eight-company post, one notes the following cases:

Diseases of the Mouth, Tonsils, Pharynx and Esophagus.—Mercurial stomatitis, ulcers of the tongue and mouth, alveolar abscesses, tonsillitis, diphtheria and pharyngitis.

Diseases of the Stomach, Intestines and Peritoneum.—Gastritis, acute and chronic, gastralgia, constipation, diarrhea, gastroenteritis. enteritis. colitis, peritonitis, appendicitis and malnutrition and digestive disturbances caused by the presence of nematodes and cestodes.

Diseases of the Genitourinary Tract.—Uremia, chronic parenchymatous nephritis, tuberculosis of the kidney, rupture of the bladder. cystitis. gonorrhea. pelvic inflammation, vaginitis, urethritis, endometritis. prolapsus uteri and syphilitic infections in practically all forms.

Diseases of the Circulatory and Respiratory Systems.—Angina pectoris, endocarditis, mitral insufficiency, aortic stenosis, bronchitis. asthma, lobar and lobular pneumonia, pleurisy, pleural effusion and filaria nocturna.

Other Diseases.—Rheumatism, tuberculous adenitis. scabies, sciatica, lumbago. alcoholism and neuralgia.

Conditions Requiring Operative Measures.—Ruptured bladder, appendicitis. placenta prævia, retained placenta, tuberculosis of kidney, osteoplastic cranial operation for bullet wound of cranium, fractures and minor injuries.

A careful comparison with previous periods shows that this range of cases during the past three months is not exceptional at this particular post, and yet, comparatively speaking, this station referred to is by no means a large one.

EQUIPMENT OF HOSPITALS AND PROFESSIONAL OPPORTUNITIES

All hospitals are thoroughly equipped for every kind of surgical work, and the medical department supplies all needs. In most posts there are also *x*-ray machines and full photographic equipment. The laboratories contain every instrument for clinical study. Original investigation is encouraged, and to those following the progress of tropical diseases it is needless to enumerate the important researches that have been completed by army surgeons.

At each hospital the leading American and several foreign medical journals are received regularly. From time to time additions are made to the hospital libraries, so that an army surgeon finds a rather complete library awaiting him at each post. Should any special work be deemed necessary by the surgeon, it is forwarded by the medical department. This would surely indicate that a physician in the service who allows himself to neglect professional studies has himself and not his environment to blame, and such a man would probably remain in the service only until his next examination for promotion. Additional stimulus to study is also found in the fact that frequently surgeons who manifest an especial interest in any particular branch of medicine or surgery are sent to medical centers where their studies can be continued.

As for the isolation referred to earlier in this paper, it is possible that at times a surgeon may be the only physician at a post, but this is rather exceptional at present, and the tendency is to concentrate troops, and have larger hospitals and more medical officers.

When in time the medical profession learns of the true position of the army surgeon, of his excellent opportunities for professional development and of his incentive to serious study, then the advice to the medical student will be to enter this career, which offers such exceptional chances for successful study and research.

PELLAGRA

A. J. DELCOURT, Sr., M.D.
HOUMA, LA.

Not the least interesting feature of the medical history of recent times, which has been so fertile in sensational scientific events, has been the sudden coming to the front of the problem of pellagra. Except in the experience of a few practitioners who occasionally encountered undisputed cases of pellagra, this disease had passed almost unnoticed for a number of years; but it has of late suddenly assumed in medical and public attention a rank hardly equaled by apparently more important public problems.

It is not desired to detract in any way from the importance attached to pellagra as a direct and serious danger to public health, a danger which is but too well attested by experience in the past and in other countries; but it may very well be that, on account of the recent discovery of a considerable number of cases in this country, and especially through sensational disclosures, mostly through the lay press, the situation has been made to assume an aspect more serious than is really justified.

The problem of pellagra is surrounded with such difficulties and obscurities that much study should be given to it before attempting to formulate definite conclusions. Scientific circumspection is the more strictly to be enjoined in that, in addition to the novelty and the unfamiliar aspect of the disease, by far the greatest number of observations have been made in hospitals and insane asylums where patients have drifted at last in the advanced stages of the disease, or else when suffering from very complex ailments. Under such circumstances the picture of the disease would naturally be obscured or distorted and the diagnosis, even by the most experienced observer, would be difficult. It is assumed that this accounts for the harrowing pictures of the disease lately drawn and for the pessimism largely prevailing in regard to pellagra.

However conflicting on some particular points, and however much wanting the evidence may be under particular circumstances, it cannot be denied that those observers who have given the closest attention to pellagra have all looked on alimentation by damaged corn as the cause of the disease. Furthermore, those countries of the old world that have been forced to a determined fight against pellagra have all centered their means of defense on that theory, and it has rewarded them with such a fair measure of success as to encourage them to continue the fight on the same lines. The occurrence of analogous intoxications from other kinds of damaged grain, such as ergotism, furnishes a strong argument in favor of accepting zeism as a factor in the pathogenesis of pellagra.

Pellagra was first noticed in Europe in the countries situated near the natural northern limit of corn culture, where the ripening of the grain was often imperfect. The variations in the severity of the disease seemed to correspond with variations in the crops. Thus, after an unseasonable year, the disease would break out in sudden explosions in the spring and assume an epidemic character, and then with the coming of better crops its violence would abate and only sporadic cases would occur.

Much is to be learned from the extended experience of European investigators whose studies on this subject have extended over a century and a half.

It is an endemic trophic disease of toxic origin, especially with vernal manifestations, and characterized by gastrointestinal, cerebrospinal and cutaneous manifestations. In its attenuated or light forms, pellagra may be ushered in by languid, tired feelings, disinclination for any kind of work, more seldom by nausea and vomiting. A few patients may experience a particular feeling of heaviness about the head or of vertigo, a look of sadness or rather of mental depression, as evidenced by the apathy displayed, or by the neglect of duties hitherto cheerfully discharged. Most often pellagra has no precursory symptoms and the disease is at once ushered in by its cutaneous manifestations. The regions most commonly affected are the dorsal surfaces of hands or feet, upper parts of the chest and sternum, the neck, and such parts of the arms and legs as are usually uncovered. Very seldom is the face affected.

The cutaneous lesions of pellagra must be considered as *erythema solare*, the result not of heat, but of the actinic rays at the violet end of the spectrum. These lesions, beginning with the spring, sometimes sooner if the winter happens to be mild, confine themselves to the unprotected parts of the skin, lasting generally during July and August, to desquamate in the fall, leaving during the winter and until the next vernal exacerbation a glossy, erythematous skin. Gaetano Strambio, in the latter part of the eighteenth century, noted that by protecting the already affected skin against insolation it can be restored to its normal condition, but the patient does not escape from the other effects of the disease. The cutaneous lesions reappear the following spring and may thus recur for several years.

In the severe forms the gastrointestinal symptoms are more pronounced, including stomatitis, vomiting and diarrhea. The nervous system is more gravely affected, depression and melancholia being extreme and diplopia, vertigo and hallucinations being experienced. A feeling of heat, muscular contractions, involuntary movements, convulsions and epileptiform attacks are observed. There is extreme weakness, especially of the back and lower limbs.

These symptoms, marking a gradual degeneration or at least an impairment of the nervous system, may be associated or not with delirium. This delirium may manifest itself under two forms—acute and chronic. The acute form may prove fatal in a few days and is attended with a high fever and a hard and vibrating pulse. Some patients are dejected and gloomy, refusing to eat and drink or even to answer when addressed. Others are noisy and obstreperous, or even furious and turbulent, and many, according to Strambio, by moving the head to and fro seem to imitate the tolling of the bells. The chronic delirium—pellagrous mania—according to the same author, assumes different forms. One of them is a kind of dementia; another form is marked by a loss of memory and attention—amnesia—and a third, much more common, is a melancholia, most often religious, with an impulse toward self-destruction, especially by drowning—hydromania. This chronic delirium is almost always incurable, though it sometimes disappears after several years of existence. In the insane asylums of some Italian provinces pellagrous maniacs constitute a considerable proportion of the inmates. According to Marie, pellagrous insanity is on the decrease in France. In other countries the number of pellagrous insane is always considerable.

To such incurable and desperate states of organic degradation has been given, in the Italian hospitals, the name of *tabes pellagrosa*, the exact meaning of which should be more precisely defined. We are here dealing with a most important point concerning pellagra and one that has contributed in no small degree toward obscuring the diagnosis and causing the disease to be misunderstood. The denomination of tabes pellagrosa has been applied to two different states, one of which is but the last degree of pellagrous intoxication. The other represents, so to say, one mode of its termination, when the toxic infection, having accomplished its deadly work, leaves the system in a cachectic condition similar to that caused by any other dyscrasia in its ultimate state, or by any other process of denutrition.

If the statement of T. Roussel is adopted as true, that most pellagrins found in an incurable state in the hospitals and insane asylums belong to this second category, there is uncovered one of the main sources of error which has caused pellagra to be mistaken for and mixed up with all sorts of cachectic conditions, thereby giving rise to those diagnoses so lightly formulated and so unjustly multiplied, pellagra of the insane, sporadic pellagra, etc.

From the foregoing I may conclude that pellagra is not to be considered, as has been done by so many observers, and is still done, as an ill-defined pathologic condition, a kind of diathesis, a gastrointestinal affection accompanied or followed by various nervous accidents, but rather as a clearly defined affection characterized by phenomena which plainly can be divided into two successive pathologic states: first, a primitive toxic, chronic disease, with vernal manifestations, the progress and degree of which are governed and determined by the occurrence of repeated intoxications; second, a cachexia and a consecutive morbid state resulting from the intoxications and from mixed debilitating conditions through which the toxic disease has been originated and has developed itself.

Now that pellagra has been raised to the high importance of a national hygienic problem and the attention of the medical profession centered on it, there can be no doubt that the obscurities that still surround it will soon be dispelled and a flood of scientific light thrown on it.

A STUDY OF THE ADMISSIONS TO THE U. S. MARINE-HOSPITAL, CHICAGO

G. B. YOUNG, M.D.
Surgeon, Public Health and Marine-Hospital Service
CHICAGO

The following statistics as to the change in the admission rate for certain diseases during the past twenty-five years among the patients in the United States Marine-Hospital at Chicago are believed to be of some interest.

Hospital statistics are not usually very interesting, and are, moreover, apt to have their values seriously impaired by the difficulty in estimating rightly the effect of the many factors which qualify their apparent import, as lack of definiteness in diagnosis, changed conditions as to staff, or varying character in the patients.

The figures for the Marine-Hospital at Chicago, however, as for the other hospitals of the service, while perhaps of no more interest than others, are singularly free from difficulties due to variability of attendant conditions, and this for the following reasons:

1. All diagnoses are made in strict accordance with an official nomenclature.

2. The patients are drawn from persons of one definite occupation and are almost all adult males between 21 and 50 years of age.

3. The method of recording the facts is uniform and fixed.

I doubt if there are two dozen civil hospitals in this country in which the class of beneficiaries, the system of record, and the nomenclature have remained so nearly uniform for twenty-five years.

The diseases selected for investigation were: (1) those among which any marked change in incidence would indicate some distinct change in sanitary, climatic or social conditions; and (2) diseases not appreciably affected by such conditions, diseases whose very uniformity of incidence would serve to make more striking change in admissions for the diseases of the first group.

In the first class I have placed enteric fever, malarial fevers, rheumatism (acute and chronic), syphilis, tuberculosis of lungs, acute bronchitis and pneumonia; in the second, cardiac diseases and kidney diseases.

About one in four patients applying for relief at our dispensary are sent to hospital; others receive treatment as out-patients, and only the actual hospital admissions have been considered. These vary in number from year to year; the average for the twenty-five years has been 560, the figures varying in round numbers from 400 to 800. The year is the "fiscal year," July 1 to June 30.

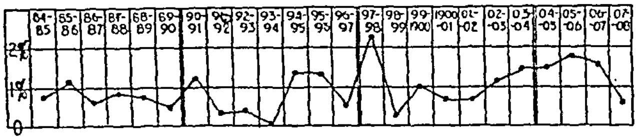

Chart 1.—Percentages of admissions for diseases of the kidney.

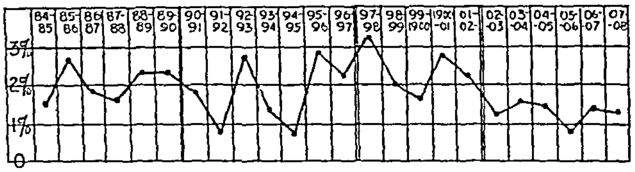

Chart 2.—Percentages of admissions for cardiac diseases.

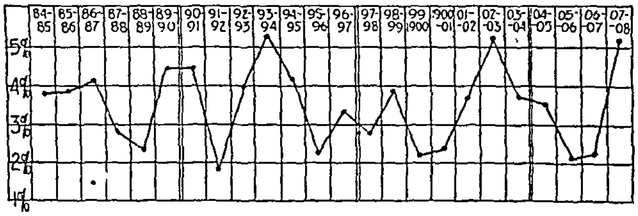

Chart 3.—Percentages of admissions for bronchitis.

One very striking fact is that among 13,500 admissions in twenty-five years there were only 9 cases of diabetes.

The charts for the diseases in the second group are first given, and a glance at them shows at once just such a lack of change in incidence as had been expected. The percentages vary a little from year to year, but the range above and below the mean are about equal.

The charts given by the diseases of the first class are found to fall naturally into two divisions: (a) those whose percentages are found to have been little, if at all, affected by changes in sanitary and other conditions, though their character would have led one to expect differently, namely, bronchitis and pneumonia; and (b) those whose percentages show very distinct changes.

I confess that I am somewhat surprised at these figures. For reasons to be explained in connection with the rheumatism table, and because the development of the use of the microscope for discovery of tubercle bacilli has eliminated many cases that might formerly have been diagnosed as bronchitis, I had expected that the table would show a progressive decline in the admissions for bronchitis, interrupted here and there by the occurrence of increases due to influenza epidemics.

The increases of the influenza years are, indeed, shown, but the expected decrease does not appear.

The same remarks apply to the pneumonia rates.

The enteric fever table shows just what was expected: a rise, a decided fall and then a steady increase, the initial rise and decline coinciding closely with the condition of the city water before and after the opening of the drainage canal, the steady rise of the last four years being a part of the well-known, but not completely explained, rise in the enteric rate among the shipping around the great lakes. The final figures leave the rate 4 per cent. against 1.4 per cent. twenty-five years ago.

The tuberculosis chart is something like the enteric chart: a sharp rise, a sharp fall, a fairly even average for a number of years and then a steady rise.

Now, there are certain facts to be considered in connection with this chart. First, the sudden fall in the number of admissions from 1889 to 1892 (from 9.4 to 4.4 per cent.) coincides exactly with the general introduction of the issue of modern microscopes to the service hospitals and the general introduction of the practice of examining sputum. One would have expected that this would have resulted in a sharp rise in the admission rate; on the contrary, it dropped more than 50 per cent.

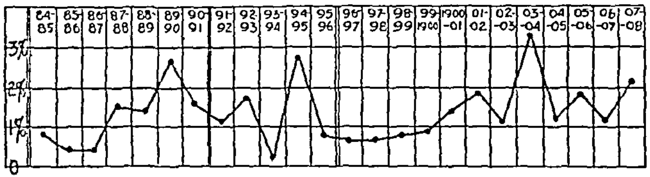

Chart 4.—Percentages of admissions for pneumonia.

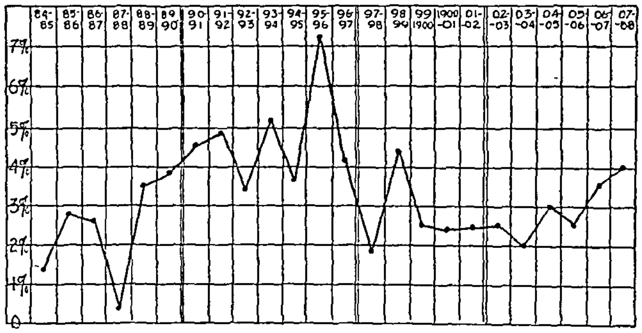

Chart 5.—Percentages of admissions for enteric fever.

In 1897-1898 the service opened at Fort Stanton a sanatorium for its tuberculous cases, and from 1901 probably 33 per cent. of the cases have been sent there, the percentages for the last three years being 40, 35 and 56.5.

Formerly patients were admitted, improved and were discharged, and were readmitted, possibly more than once, either here or at some other service hospital, each time of admission counting necessarily in the tables as a new case. I am sure that at least 15 per cent. of the admissions for tuberculosis prior to 1900 were readmissions. It follows thus that for the decade from 1890 to 1900 the net admissions were just about 4 per cent. and were strikingly uniform in number. Now, from 1900 on, the readmissions of patients coming in the same year as original admissions ceased to be an important factor. Yet just at this time apparently begins the steady increase of from about 1.5 to 2 per cent. a year.

Turning to the out-patient figures, we find that their numbers have decreased to the vanishing point; last year there were three, and year before none. Now, of course, this is due to the policy of treating as nearly as possible all cases of tuberculosis in hospital, a policy I have strongly enforced for the past four years, and I have, therefore, examined the out-patient figures for a number of years back to see if they gave any explanation of the gradual rise in the admission rate.

They do not explain it; on the contrary, they emphasize it, for the total out-relief and hospital relief in 1898, the year before the segregation plan got to working, was exactly the same as last year, when the system had been ten years in operation. Moreover, the figures which I have prepared for the whole service during the past twenty years show a decline in the amount of tuberculosis treated.

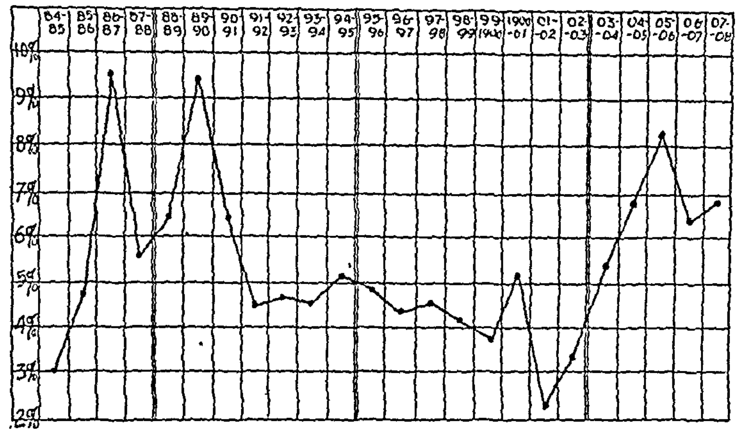

Chart 6.—Percentages of admissions for pulmonary tuberculosis.

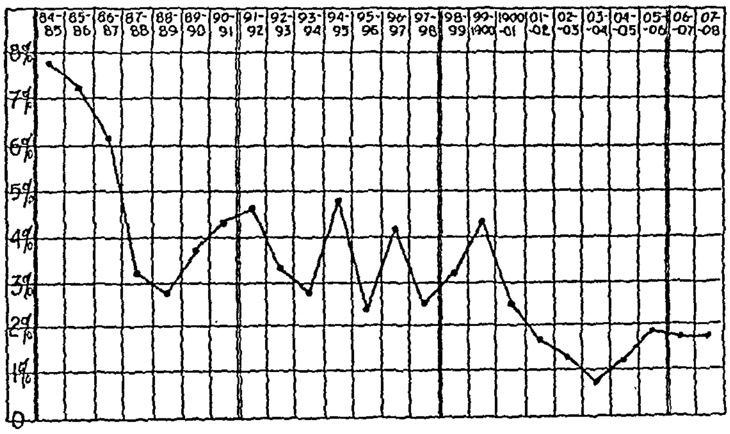

Chart 7.—Percentages of admissions for malaria.

The Chicago figures, therefore, seem to indicate clearly an increasing prevalence of pulmonary tuberculosis among the merchant seamen frequenting the port, in the face of a declining rate for merchant seamen generally.

We come now to the three most striking results of the investigation, viz.: the charts for malaria, rheumatism and syphilis.

The malaria chart illustrates strikingly the necessity of understanding all of the qualifying circumstances if one hopes to make intelligent deductions from medical statistics; it also illustrates how often such qualifying circumstances are entirely outside of the normal professional horizon—are, in fact, dependent on economic or industrial causes. At first glance it shows a very striking and steady decline in malarial admissions, from nearly 8 per cent. of the total to below 2 per cent., in round number a decline of admissions for malaria of 75 per cent., giving the impression of a great improvement in the prevalence of malaria about the lakes.

There has certainly been a great improvement in this respect as far as concerns Chicago and vicinity, for twenty to twenty-five years ago there were suburban sections and sections along both north and south branches of the Chicago river which were distinctly malarious; but the two main factors in this improvement are industrial. They are the decline in steamboating on the lower Mississippi and the rise of the great lumber, iron, copper and transportation corporations engaged in business about the lakes.

Formerly when navigation closed on the lakes there was an extensive migration synchronous with that of the ducks and geese. When serving at St. Louis, Cairo and Memphis I came to know a good many of the regular migrants who came and went year after year, but the migration was then already becoming a thing of the past.

It was these men who, coming north infected, formerly furnished a large quota of the malaria which was responsible for from 6 to 8 per cent. of our admissions. We still get a few such cases every year, but not many.

There was formerly a large fleet of schooners and small steamers on the lakes engaged in carrying lumber, etc. They entered the smaller harbors, and often loaded almost alongside the shore. Moreover, they discharged along the south and north branches and were apt to lie some time at the bank. At the present time the large steamers load mechanically with great rapidity at great terminals, often miles from the close vicinity of the forests and mines, and discharge as quickly.

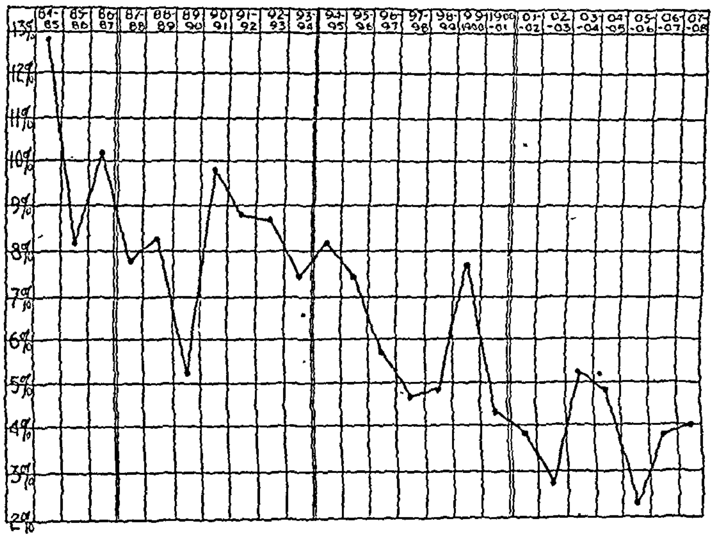

Chart 8.—Percentages of admissions for syphilis.

The chart mirrors these changing conditions very clearly. The decline in the river shipping was rapid after 1885 and coincides with the sharp drop in the curve. Then for about ten years this apex vibrates up and down with fairly even excursions above and below 3.5 per cent; and, finally, there comes the sharp decline of the past decade, coinciding closely with the rise of the great companies and the disappearance of the schooners.

Here at last in the syphilis chart is one which can be considered entirely on the basis of the sanitary or medical facts in the case; and I cannot see how it can fail to interest greatly those concerned with the "venereal peril." Here are the figures of admissions for twenty-five years among 13,500 young adult males of as nearly as possible the same class and suroundings, and they show a decline from 13 per cent. to 4 per cent. of the admissions, and a steady regular decline as well.

A word as to diagnosis. The service regulations require that the cause, not the manifestation, of a dis-case he stated. That is, for example, a tabes due to syphilis is entered "syphilis, secondary," and under "subsequent complications" it is entered "tabes," in brackets. This is the uniform and prescribed system; so the question of terminology cuts no figure in the result shown by the chart.

The decline is certainly not due to increase in the morality or sobriety of our beneficiaries, nor in their character; indeed, the latter has declined, the English, Irish and American sailors having to some extent given place to a very low order of foreigners. These last possibly drink less whisky and certainly fight less than their predecessors, but I think that they are less often married.

What, then, is the cause? Three solutions suggest themselves:

1. A decline in the prevalence of syphilis.
2. An improvement in diagnosis and treatment, resulting in fewer of the severe eruptions and crippling, late lesions.
3. An attenuation of the virus by reason of a more general syphilization of the class.

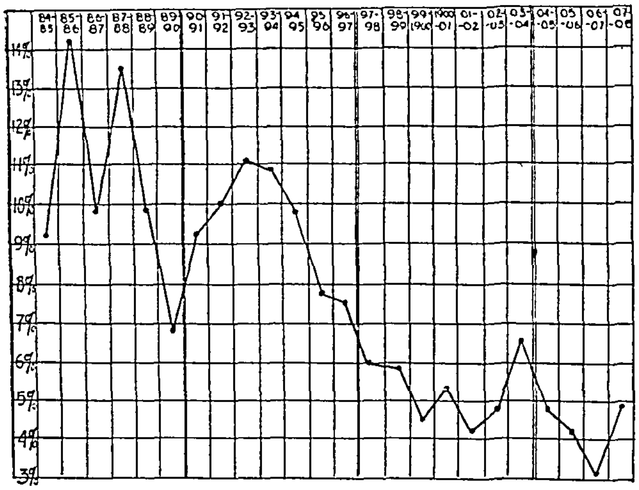

Chart 9.—Percentage of admissions for rheumatism.

I do not believe that the first is true. The statistics of the country generally are said to tell a very different story.

The second explanation is unquestionably sound. We, like the profession at large, twenty to twenty-five years ago did not so accurately draw a distinction between chancre and chancroid, and so more patients remained without constitutional treatment until their secondary stage was well developed; moreover, the very number of such cases made us less considerate of the individual patient, and they were discharged earlier and were hence more apt to relapse in later years.

The third reason is the one which, I think, is mainly responsible for the decline. It is a personal opinion merely, I know, but I have held it for some time; and, indeed, I began this inquiry because I thought that the syphilis I was seeing seemed much diminished in severity and I debated whether the cases were really fewer as well as lighter. This is not the place to argue the matter, but I state it as my opinion that there has been a decline in the severity of syphilis due to the wider prevalence of this disease—in other words, to an attenuation of the virus.

In Chart 9, again, is a chart that is worth attention. The steady and almost uniform decline is most remarkable and the cause is as plain as the results are striking. The decline in rheumatism is the direct result of the enormous improvement in the conditions under which the men work and sleep. Gone are the sailing vessels and small steamers with their drenched decks, hours of exposure on watch and the turning-in in cold, damp, unheated forecastles. The absence of work aloft and on deck on the steamers and their higher free-boards have radically changed the conditions on watch, and the living quarters are comparatively warm and dry.

Looking back at the bronchitis and pneumonia charts, it will be noticed that these diseases have somewhat increased, and it was stated in that connection that this was a surprise at first. On reflection, however, it appears that the reason for these increases is the same as that for the decline of rheumatism.

The sailor has been replaced by the fireman. He escapes the diseases associated with cold and exposure; he does not escape those due to sudden exposure when overheated.

THE PROPHYLAXIS AND TREATMENT OF GASTROENTERIC TOXEMIAS OF BOTTLE-FED INFANTS IN SUMMER

JUDSON A. HULSE, B.S., M.D.
AKRON, OHIO

One-third of all infants born into the world die before the third year, and the majority of these deaths can be attributed to gastroenteric toxemias of summer. About 85 per cent. of these deaths occur among bottle-fed infants.

In preventive medicine we encounter social as well as medical problems. The saving of the lives of infants from preventable disease is as much a social as it is a medical problem—so long as tenement builders are permitted to construct dwellings for human habitation without regard to provision for adequate systems of light or ventilation, and are allowed to fill them from basement to garret with men, women and children huddled together like sheep or cattle. So long as cities and municipalities permit the sale of unwholesome milk just so long will infant mortality be a stigma and a disgrace on our state and national life.

The saving of the lives of these infants is a greater problem than that of race suicide, and an infinitely more practical one, and as such demands the attention, not alone of medical men, but of public men, high in authority, who ought to be engaged, a portion of their time at least, in enacting laws safeguarding the lives of infants.

In the cities of Ohio, with but few exceptions, health officers are more concerned with the problem of unwholesome milk than with congested tenements, with their accompanying filth, squalor, foul air and poverty, since these latter conditions do not prevail to any extent.

Certified milk is fast coming to the rescue, and is the means, no doubt, of saving many lives, but its imperfect system of production and delivery and the higher cost often place it beyond the reach of the poor families who need it most. Moreover, it has other disadvantages; the babes who are fed on it are constipated and do not thrive; nor do they show the same rate of gain as do infants fed on less wholesome but fresher milk. These disadvantages are slight, however, when we consider the greater freedom from nutritional troubles which certified milk assures. In Akron a splendid plant is in operation for the production of certified milk, and the health board bacteriologist informs me that the bacterial count is as low as 7,000, while ordinary milk being sold in the city shows a count of 2,000,000. There has been some trouble with the delivery system. Some of the milk is 24 hours old when it reaches the consumer, and when kept for use another 24 hours, or 48 hours in all, it is entirely too old for infants during the hot months, unless we can be absolutely sure of its proper handling before and after delivery. I am informed that the bottles are to be stamped in the future, so that the consumer may know the age of the milk when received. This I consider a most vital matter.

Certified milk holds an important place in the reduction of infant mortality, but it cannot compare with reasonably clean milk fresh from the cow as a food for infants at any season of the year. Many cows are kept in the city of Akron and its immediate vicinity, and I have been advising families either to own a cow or to get milk from some neighbor's cow for the baby's use, instructing the mother in detail as to its proper care and preparation. I have yet to see a single case of infection from milk so obtained and cared for. It will be objected that there are only a comparatively few people who can obtain milk in this way, and this is true; but, on the other hand, there are many who could obtain such milk who are not now doing so chiefly because they are told that certified milk is the best obtainable for the baby, which is only true when fresh milk is not to be had. If certified milk for any reason is also out of the question, and ordinary milk must be relied on, then let it by all means be pasteurized during the excessively hot weather. Most of the objections to pasteurized milk are of but little consequence, since it need be done only for a period of three months; moreover, mothers can be taught to pasteurize milk by some simple home method.

At some future day we shall be able to procure wholesome milk at a moderate cost. The various milk commissions and health protective societies and organizations of like nature are carrying forward the work of education to such an extent that people are beginning to demand clean, wholesome milk, and the dairyman is coming to understand that unless he produces it he will be driven out of business by the stress of competition.

When the milk question is once solved, then the greatest of all factors in infant mortality shall have been conquered.

Mothers should be taught the great value of keeping the baby out of doors night and day during the hot months. This I consider next to clean milk in importance. The more fresh air the infant gets the better will be its digestion. I have repeatedly seen infants who were unable to digest properly any modified food mixture when kept indoors, go on to perfect digestion and assimilation on precisely the same modification when the tonic effect of fresh air was added by keeping the baby continually in the open air. Babies do not get fresh air enough, ill or well. "The catch cold fear" of most mothers is so firmly grounded that it will require generations to overcome it, but the fresh air camps, day nurseries and other fresh-air organizations are accomplishing much in the way of education, though much teaching yet remains to be done.

Heat is another factor in the production of gastroenteric disease—a temperature range of from 74 to 90 F. degrees being especially dangerous. I discovered that most of my cases of infection resulted from the 10 p. m. feeding, due, in my opinion, to two factors—the milk is older at this time and the nursery excessively hot. I found that during the hottest nights of last July the temperature of the average upstairs sleeping room was 10 degrees higher than the air on the downstair porches; for example, when the temperature was 81 F. in the nursery at 10 p. m. it was found to be but 71 on the downstair porches. To put a baby to bed in a room at 81 F. invites an attack of indigestion by heat depression and by raising the child's temperature to such an extent that the growth of pathogenic bacteria ever present in its alimentary canal are thereby favored, and when to this is added warm milk, 24 hours old or older, the conditions are most favorable for an attack. On the other hand, if the child is placed out of doors on a properly protected and screened porch to spend the night, with the temperature at 71 F., and gradually dropping, the factor of heat is eliminated, and the infant's digestion is assured by the stimulating and tonic effect of the fresh air, and therefore the danger of night infection is reduced to the minimum.

Over-feeding is best avoided by giving the baby an abundance of fresh boiled water to drink. The destruction of flies is important. Good serviceable screens are a good investment. Light clothing and frequent cool bathing are essential. Unceasing diligence in all hygienic matters is paramount in the prophylaxis of gastroenteric toxemia.

In the treatment of this infection a number of general principles are to be observed.

First, the withholding of all food for at least three days is imperative; after that time barley water may be given.

Second, the child should rest in bed out of doors. No child should be permitted to creep or to sit up even if apparently able to do so.

Third, the toxins should be eliminated by stomach washing, colonic irrigation and catharsis. As a rule these attacks assume such an alarming character at the onset that the physician is called in early, and there is no procedure so valuable as stomach washing, using boiled water at a temperature from 100 to 110 F., to which may be added a small quantity of lime water. Two drams of castor oil should be given through the tube before its withdrawal—a thorough colonic irrigation should follow, and after the stomach is settled cooled boiled water may be given freely by the mouth. This is all that is required in the majority of cases, and the child will be apparently well in three or four days. In cases seen a little later, stomach washing is not indicated unless that organ is irritable, but colonic irrigation should be done every four hours the first day of treatment—after that twice daily is usually sufficient. This should be followed by nutritive enemata at intervals of four hours. The rectal feeding should be continued until it is safe to begin feeding by mouth. If the rectum protrudes and becomes irritable, the application of a 5 per cent. ointment of cocain will be found efficacious. Calomel should follow the oil, but the less medication used the better. These infants are over-drugged, and thus the irritation is increased and prolonged, especially by calomel. Abt,[1] of Chicago, has recently shown by a "series of experiments the irritating effects of the common cathartics on the intestinal mucosa of infants. The benzidin test was used for blood. Calomel, magnesium sulphate and castor oil were the cathartics given. Both blood and mucus were shown in the stools after a few days. Calomel produced the greatest amount of irritation." When we consider how delicately the intestinal mucosa of an infant is constructed, it is well to be cautious in the administration of cathartics.

---

[1] Archives Pediat., November, 1909; abstr. in The Journal A. M. A., July, 1909.

Fifth, of measures to control temperature and restlessness, a tub bath is the best. The child can be in the tub from ten to twenty minutes out of every two hours if necessary. An ice cap to the head is useful.

Sixth, the following measures may be used to allay the inflammation: In addition to rest in bed and after thorough cleansing of the alimentary canal, bismuth subnitrate may be given, from 1 to 2 drams daily, for a child one year old. Salol, 1 or 2 grains every three hours, is of some benefit as an intestinal antiseptic. Opium is indicated if there is much pain and continued frequent stools. It has been used too freely in the past and should not be given at all if cerebral symptoms and high temperature are present. Opium is useful in convalescence, when the taking of food is followed by a movement of bowels. In cases of a cholera infantum type with threatened collapse, it may be given hypodermatically in the form of morphin sulphate, 1/100 of a grain, with 1/1200 grain of atropin. This dose is suitable for a child of one year. For the prostration so often present, brandy should be administered by adding it to the boiled water, which the infant takes to allay thirst—½ oz. in 24 hours. Hypodermoclysis may be necessary in the graver cases. During convalescence tonics are indicated, and beef juice should be given freely. Organic iron in a liquid form to which is added Fowler's solution is a convenient method of administration. Lastly, removal to the country or seashore in those cases in which relapses are prone to occur will accomplish more than anything else in restoring the infant to health.

The use of antitoxin has not yet reached a practical basis in the treatment of gastroenteric disease of infants. I have, therefore, omitted its consideration in the preparation of this paper.

INJURY BY ELECTRICITY*

JOHN J. MOORHEAD, M.D.
Instructor in Surgery, New York Post-Graduate Medical School and Hospital; Attending Surgeon, Red Cross Hospital; Assistant Visiting Surgeon, Harlem Hospital
NEW YORK

In view of the widespread and increasing industrial use of electricity it is not surprising that electric trauma is on the increase and that cases thereof are being cited in medical publications. Despite this, authoritative information as to the physical effects of electricity is very scanty,[1] especially in American literature. In Germany (notably through the investigation of Jellinek[2]) and in France and Great Britain, there has been much preliminary experimentation and subsequent case reporting by physicians; but in this country investigation has been limited almost solely to electric engineers, and case reports have been few in number. This is my excuse for bringing the subject before the section as this paper aims to narrate what has been learned from personal observation and a very considerable search of the available literature.

TECHNICAL TERMS

For an intelligent understanding of the matter, it is necessary to know some of the usual technical terms, and they can be stated thus:

> The *volt* is the unit of pressure. The *ampere* is the unit of strength. The *ohm* is the unit of resistance. The *coulomb* is the unit of quantity.

But for all practical medical purposes it is enough to remember that volt is the unit to express pressure, intensity or electromotive force; and that the ampere denotes strength or current quality. The volt is the impelling force which moves the electricity through any conductor. The ohm is the unit of resistance and expresses that quality of the conductor which resists the passage of electricity through it.

Electricity flowing through any conductor is impelled by the voltage of the circuit and is opposed by the resistance of the conductor. The size of the current which flows is directly proportional to the voltage and inversely proportional to the resistance. This "size" is measured in amperes, the ampere being the unit of current, and its numerical value is found by dividing the volts by the ohms; ($A=V/O$; "Ohm's Law"). Ordinary conductors carry currents of three varieties: direct (or continuous); alternating; and interrupted.

The contact may be of four kinds, viz., *positive,* where the body is firmly and constantly pressed against the conductor; *partial,* where the contact is slight and steady; *brushing,* where the contact is slight and for a short interval, and *arcing,* where the current reaches the body via a vapor through which the current passes. The *intensity* may be (1) *low* (100 to 300 volts); (2) *medium* (400 to 600 volts); *high* (1000 volts and over); this classification being that adopted by Prevost and Batelli, of Geneva, as the outcome of many experiments.

The *duration of contact* may be (1) *short,* from one to five seconds; (2) *medium,* from five to eight seconds; and (3) *long,* from eight seconds upward.

Mode of receipt is generally by charged (1) wires or rails; (2) metal apparatus or tools; (3) flashes or arcs which are productive of burns only.

The average electric pressure in electric lighting is from 100 to 225 volts (direct), usually about 110 volts; in overhead and underground trolley systems from 500 to 600 volts (direct); suburban lighting circuits 1,000 to 2,000 volts (alternating); series arc lighting circuits 2,000 to 4,000 (direct or alternating); in overhead, long haul railway systems (as the N. Y., N. H. & H. R. R. Co.) 11,000 volts (alternating). In the third rail systems, like the local subway, the voltage is about 550 (direct). The highest voltage transmitted by wire in this country is that generated from Grand Rapids, Mich., 100,000 volts. Another system in Denver transmits 88,000 volts, and one in Los Angeles 75,000, and that from Niagara Falls 60,000.

A voltage of from 200 to 500 is usually not dangerous, but the alternating current is considered to be more dangerous than the direct. In the electrocution of criminals from 1,300 to 2,000 volts are used, the average being 1,700 of the alternating type.

FACTORS INFLUENCING PHYSICAL EFFECTS

The physical effects are mainly determined by the following:

1. Amount and duration of current.
2. Site, type and area of contact.
3. The individual.

[2] Jellinek, S.: Numerous articles in German medical journals.

Amount and duration of current is the main essential, and the greater the degree and the longer the duration, the greater the effect. High voltage, long duration and positive contact generally predicates coma, severe systemic shock, burns and oftentimes death. Medium intensity, with medium duration and partial contact, generally means burns of the second or lesser degree, less profound coma and shock with more or less paresthesia, especially numbness and tingling. Low intensity, with short duration and brushing contact generally means burns of the first degree or none, slight, if any, coma, and moderate paresthesia mainly of the tingling type. Low intensity, with brief duration and partial contact, generally means absence of burns or systemic symptoms, paresthesia of the formication type being generally alone complained of.

Amperage is so variable that it has not been mentioned because of its uncertainty, but the higher it is, the greater the effect in general.

Site, type and area of contact is less important, pursuant to the physical law that electricity takes the shortest route between two electrodes, and this has led to investigation to determine the resistance of various bodily elements to the transmission of electrical energy. It has been found that the tissues transmit proportionate to the amount of their fluid constituents; the more saline this is, the better the conductivity. Blood is the best conductor, mainly because of the saline serum. Muscle comes next, nerve tissue follows, and bone is a poor conductor. Similarly, experiments have shown that the bodily tissues exert varying resistance to the passage of electricity, as denoted by the unit of resistance, the ohm. The average human resistance is 1,000 ohms. Dry skin is very resistant, and one observer (Jolly) says that this is 150 times greater than that of the underlying tissues. A dry, hard, thick skin offers more resistance than one that is moist, soft or thin; an acid or alkaline perspiration reduces the resistance, while an oily skin raises the resisting power. If a strong alkali be applied to the skin so that the oily secretions are removed, the resistance is much lowered, so that the subject experiencing little effect from 100 volts might be disturbed by 10 volts. Larrat[3] says that if muscle is given a standard resistance of 1, then nerve and cartilage can be denoted by 2.5; bone as 15 to 20; and the skin and epidermis as between 100 and 500. Electric energy meets greater resistance passing transversely *to the axis of a tissue than* when [illegible] insmitted longitudinally, this being 6:1 in muscle, [illegible] in nerve fibers. Turner's experiments indicate that transmission *from hand to* hand *meets* with a resistance of 1,375 ohms; through one hand 900 ohms; from cheek to cheek 600 ohms; from one supramalleolar region to another 700 ohms; and through the calf of leg 350 ohms.

As compared with any metal, the body is a poor conductor, it being calculated that muscle is 115 million times a poorer conductor than copper. It has also been estimated that one inch of the sciatic nerve has eight times the resistance of the Atlantic cable.[4]

The greater the area of contact, the greater the effect, especially if the current traverses vital parts, notably if the heart is in circuit.

The individual variation means the personal equation, and it is strikingly similar to that of drug idiosyncrasy, notably as to sex, age, physique, occupation and temperament. Males are less affected than females; the aged offer less resistance than the young on account of the constituents of the blood vessels; those of rugged and muscular physique have a greater conductivity than those of the *opposite* type; the phlegmatic are subjectively less prone than the neurotic; those accustomed to electric energy are often less influenced than the novice. Illness, *sleep and alcholism render persons less* sensitive.[5]

Variations as to time of day, type of clothing, amount of food in the stomach and general well being, all seem to exert some influence; but the given effect cannot always be determined by these factors, and I have known electric workers to have practically no effects from contact under circumstances that left no doubt as to high voltage traversing the system.

PHYSICAL EFFECTS

In a general way these are three in number:

1. Death.
2. Burns.
3. Nervous symptoms.

Death.—Death from electricity is usually sudden, and is best represented by the execution of criminals, lightning stroke and unexpected contact with highly charged materials, the body completing and short-circuiting two conductors. Under such circumstances there may or may not be decided external evidence of what has occurred, any such taking the form of burns of varying degree, areas of lividity or ecchymosis, or simple crimsoning to mark the place of entrance or exit of the current. It is, however, very unusual for a lethal dose of electricity to fail to leave some visible evidence at the points of contact. Postmortem, such cases are surprisingly free from gross microscopic changes, and the most careful search of all the tissues has as yet failed to give any adequately uniform cause of death. The findings in general are not unlike those following drowning or suffocation. The body of Czolgos, assassin of President McKinley, was subjected to the most minute scrutiny, especially by Spitka's examination of the brain and cord, but nothing more than the customary fluidity and venous stasis of the blood with flaccidity of the heart muscle was found. In a still more recent autopsy of an electrocuted murderer the same negative findings were recorded. Observers appear to have two main theories to account for death under such circumstances; one being that the heart muscle is paralyzed by a tetanic spasm analagous to that observable in skeletal muscle under high voltage; and the other theory, that there is a definite cellular destruction, especially of the vital centers. In connection with this last, it has occurred to me that the disintegration that seemingly takes place may generate toxic materials, thus adding a chemical to a mechanical irritation that almost immediately kills. Death from low tension current is by heart fibrillation; heart and respiration alike fail from lethal medium tensions; and respiratory failure is the cause of death in high tension accidents.[6]

Burns.—Burns by electricity differ from those due to extremes of temperature only in origin, and they may be of the usual first, second and third degrees. An electric burn is an index of resistance of the tissue affected, and always indicates that the full strength of current has not been received. The character of the burn is sometimes determined by the type of metal acting as a conductor, and burns by arcs and flashes from copper conductors sometimes produce less severe burns than those emanating from iron or steel. By contrast with burns due to flame, or contact with steam, hot solids or liquids, deep electric burns are apparently less painful, produce less systemic shock, and heal more quickly. This was vividly impressed on me in a recent Harlem hospital service, where in adjacent beds lay patients who sustained irregularly distributed burns of all degrees in an incendiary fire, and also those who had received "third rail" burns; the former had more systemic symptoms, the burns were more intractable to treatment, and the complaints of pain were greater than in the latter class of cases. This is probably due to the fact that electric destruction of tissue is sudden and absolute, as if done by electric cautery. The contrast is even greater by comparison with burns from hot liquids, such as boiling water, oil or tar, and this irrespective of the surface areas involved. The resultant scarring and contraction appear about equal, even though electric burns are often more diffusely distributed over widely separated areas than burns of other kinds. If the clothing is ignited, there is added the element of heat burns to those which may be the direct result of electric contact. Examples of "third rail" burns are shown in the annexed illustrations (Figs. 1 and 2).

Burns resulting from partial or arcing contact often heal slowly and show a tendency to slough or to become gangrenous, especially if the trophic supply be involved. Cases of this type sometimes give external signs disproportionate to the underlying damage, and the severer symptoms may be a few days in appearing, and then show as isolated or confluent areas of a more or less gangrenous type. From the time of receipt of burns of this kind to the outbreak of severer manifestations, the interval period is always filled by symptoms indicative of more or less deep seated damage, in addition to the superficial evidences.

REPORT OF CASES.

As chief surgeon of the Metropolitan and Interborough Railways I have had many opportunities to examine cases of electric injuries, and one of the worst of these was the following:

CASE 1.—*History.*—S., a laborer, was working in a manhole repairing the "channel rail" of one of the surface roads, the current of 550 volts being turned on. In some manner he fell against this charged rail so that his back contacted at about the lower scapular level, his feet being grounded on concrete.

Examination.—He remained in that position several minutes and when released was found to have a third degree burn that practically escharred his back from mid-scapular to the lower lumbar region, and it is said that the burn reached far enough to expose the underlying viscera. He suffered profoundly from shock and was unconscious, and his recovery was protracted. Even at this date (6 years later) there is an unhealed area about 3 by 4 inches in the central portion of the scar, but all except this space cicatrized without skin grafting in a remarkable way considering the original extent and severity of the wound.

Subsequent History.—Some years later he was seen and exhibited by me, and at that time he had a butterfly-shaped scar 13½ by 11 inches in the involved area, in the lower portion of which was a supposed lumbar hernia. The scar had contracted enough at first to almost draw the wings of his scapulæ together and spinal flexion was impossible; but by continued self-bending and manipulation of his back, he so far recovered as to be able to resume manual labor. Later he was operated on by me and the supposed lumbar hernia proved to be retracted bundles of muscle fiber. The above mentioned unhealed areas were covered by autogenous Thiersch grafts, but healing was not yet complete in January, 1910. He at no time developed a traumatic neurosis (Fig. 3).

CASE 2.—*History.*—Another severe case was that of D. H., aged 23, ironworker, born in Finland. He was working on an iron trestle repairing overhead wires of a suburban electric and steam railroad, and, while assuming an upright position, his left occipital and clavicular regions contacted with a wire bearing 11,000 volts, and he became temporarily unconscious. Through the courtesy of Dr. F. B. Littlewood he was seen with this physician ten days later at the New Rochelle Hospital, and at that time he was able to be out of bed for a portion of each day.

Examination.—He then presented numerous sloughing and granulating burns of the left upper extremity and chest, and an extensive third degree burn of the left occiput and of the soles of the feet. He had little if any systemic shock or sepsis. There was no nervous involvement organically or functionally. Mentally he was as apt as could be expected, considering the fact that about one-sixth of his body was more or less badly burned.

The duration of contact in this case could not be ascertained, but it must have been short and imperfect, as it is to be noted that the contact was on the head and the left upper extremity, and that he was grounded by his feet standing on a metal support so that the main part of his body was temporarily a part of the circuit. He wore no hat, and his shoulders were bared except for a thin shirt, and he had no tools in his hands. Theoretically this man should have been unable to withstand electric shock of that volume, but the burns evidenced the fact that only a portion of the voltage was received. I am told by Dr. Littlewood that he made an excellent recovery, and that his progress and subsequent symptoms were those typical of severe burns.

CASE 3.—*History.*—I am also indebted to Dr. Littlewood for notes of the case of J. M., who was working on the same railroad and who came in contact with a transformer so that his left shoulder apparently received 11,000 volts.

Examination.—He immediately became unconscious, and when seen at the New Rochelle Hospital by Dr. Littlewood, had severe burns of the entire left half of the body, and the sole of each foot showed two large blebs about the circumference of a dollar. His temperature ranged from 98 to 99.4, pulse 99 to 120, respirations 20 to 40. The next night he began to vomit, and developed an uncontrollable singultus. The vomitus became biliary, and assumed the type seen in gastroduodenitis following severe burns of this or other origin.

He died early on the fourth day apparently from systemic shock. In this case the manner and duration of contact was problematical, but it is stated that the contact was for an appreciable time and that he was probably grounded on metal judging from the blebs of the feet. It is to be noted that the respiratory rhythm was more disturbed than that of the heart, and that his temperature was at no time more than one-half degree below normal. Death in this instance was probably due to respiratory failure accompanied by paralysis of the diaphragm. No autopsy was permitted. The cause of the gastroduodenal symptoms in any class of severe burns has never been satisfactorily explained, and it is generally a bad feature.

NERVOUS SYMPTOMS

In the absence of direct destructive or inflammatory damage to nerve fiber and the subsequent development of a more or less localized neuritis, the nervous effects are almost invariably those of the hystero-neurasthenic type, it being rare in my experience to find either neurosis separately as a consequence of electric or any other form of trauma. I have never known an organic disease of the central nervous system to develop from the passage of electricity through the body, nor does the available literature narrate more than one instance of this nature. If a direct injury has been done to nerve fiber, the symptoms will be those corresponding to the distribution of the affected nerves, and hence no description is needed.

Where direct injury to nerve tissue is absent or minor in extent, the subsequent development of neurasthenic and hysterical symptoms is generally psychic in origin or dependent on auto- or hetero-suggestion, and the signs then presented are usually disproportionate to the actual physical damage sustained. Such cases rarely present objective evidences of electric contact and occur usually in those predisposed because of a neurotic or actually hysterical temperament. The flash or spark or arc from charged metallic contacted points occasionally induces this set of nervous symptoms, either with or without bodily contact. Cases of this and allied sorts are often designated by the term "electric shock," and less frequently as "electric neurosis;" but the symptoms do not differ in any essential respect from the ordinary shock or neurosis attributed to any other trauma.

Examination of such a patient develops a wealth of subjective symptoms and a poverty of objective symptoms, and the average case will correspond to the following:

Case 4.—*History.*—Mrs. F. was alighting, during a rain, from a suburban electric car operated by the overhead trolley system. While she had one foot on the car platform and the other on the metal step, her hand being on the dash handle, she claims to have received a "shock," the force of which threw her face downward to the ground. She was stunned but not unconscious, did not vomit, and when assisted to the adjacent sidewalk was able to discuss the occurrence with some show of agitation and not a little anger. She walked unaided to her home near by and saw her doctor some few hours later. He gave her lotions for the bruises of the knee, elbow and hands. There were no burns or obvious electric effects, but she did complain of tingling and needle sensations in the hand that touched the dash-handle and in the foot that contacted with the metal step.

Examination.—When I saw her some fourteen days after the accident she was abed, somewhat pallid, and had a characteristically tense and drawn expression, and was markedly irritable in manner and speech, all of the foregoing being said to be foreign to her normal state. There was an obvious rapid tremor of the closed eyelids, about the angles of the mouth, and of the outstretched fingers and protruded tongue. External evidences of injury were lacking aside from a fading area of bluish discoloration over a palm-sized area just above the right knee, probably from her fall. No evidences of electric contact, or of so called "electric shock" were apparent. No paralyses and no areas of diminished sensation; conjunctival and pharyngeal reflexes absent; marked demographia; knee-jerks lively, all others normal. Romberg sign marked; no Babinski, or allied manifestations. Gait was normal and pulse rapid. There were areas of shifting tenderness along the spine, these being very inconstant and readily brought out by suggestion. Two spots were found in the upper dorsal region consistently tender, but she leaned back in a chair on these same areas and made no complaint. There was no contraction of visual fields, and no color distortion. Here is a typical case of the milder form of recoverable hystero-neurasthenia, and she had many symptoms that might as well be stigmatic as symptomatic. She recovered perfectly in a short time.

Contrasted with the former mixed type of functional nervous disturbance, the following case of almost typical hysterical motor paralysis with milder neurasthenic symptoms is narrated:

Case 5.—*History.*—G., an electrician, was admitted to the Harlem Hospital in Dr. H. A. Haubold's service with a history of having been injured two weeks ago in an out-of-town power house, the patient stating that while holding a dead wire in his left hand, someone turned on the current of 110 volts and his hands and fingers were burned; immediately fingers of the left hand contracted; it felt as if an electric current passed through him every time his fingers were touched; he claims to have lost all sensation over entire left upper extremity; and says that he cannot move his fingers; he has had other electric burns, but was never affected in this manner before; the current entered the palm of the left hand, but the place of exit is unknown.

Examination.—On examination the left hand presented the pseudo-Dupuytren's contraction appearance indicated in the annexed photograph (Fig. 4), palmar flexion at the metacarpophalangeal joints of the inner four fingers being marked, that of the ring and little finger being most prominent. There was no apparent atrophy, nor was there any burn or other sign of trauma. He would not permit the slightest manipulation of the extremity except when his attention was diverted, and then the fingers could be partly extended. He claimed loss of thermal and tactile sensation over variable areas from the elbow down; but these shifted, especially on suggestion, and followed indefinite nerve distribution. Active motion of the wrist was limited; that of the elbow and shoulder normal. He would not permit passive motion, nor would he consent to electric tests. The examination as to his general state showed him to be in excellent condition except that he was of neurotic type and presented many hysterical stigmata and neurasthenic manifestations.

During the fortnight intervening between the accident and his entry to the hospital, he was under the care of a physician, who had given him some internal medication with local application of iodin, and who is said to have made a diagnosis of "paralysis from electric shock." At no time were splints or retentive forms of apparatus employed. He would not consent to the proposed anesthetization, nor would he allow a dorsal splint to be applied, and accordingly he was dismissed from the hospital with a diagnosis of "hysterical paralysis of hand." There was unquestionably an element of voluntary exaggeration in this instance as so often happens in that class of case in which litigation is pending. When seen a month later he had regained function enough to do his usual work but still had many subjective complaints.

Occasionally there are recorded cases in which blindness and deafness and other special sense defects have been attributed to electric contact or flashes, but all instances of this sort are of the hysterical variety, and fall into the class of so-called "fright neuroses." An example of this sort came to my notice recently in which "blindness" was said to have been induced in a susceptible woman by the flash and spark display when an overhead trolley wire was struck by a metal beam. She was seated in her room some two hundred feet away from the scene of this brilliant display of light and sparks but within sight and sound of the occurrence, and she claimed that she experienced the sensation of a ball of fire dancing before her eyes, and she immediately became sightless. Examination showed no organic defect of vision; the case was one of hysterical amaurosis induced by fright in a susceptible person. Vision returned within a short time.

OTHER EFFECTS

Crile[7] says that high tension currents produce no chemical change of importance in the various tissues and organs aside from the burning at the place of contact, and that the blood is unaltered. To prove this, a current of 2,300 volts (alternating) was passed through the head of an animal, and during the ensuing month of observation there was no discoverable loss of function. The same observer also says that when atropin is administered before the current is applied, the inhibitory effect is almost wholly obviated, except when the current passes through the heart muscle and then death ensues.

TREATMENT

Treatment presents no special problems, inasmuch as it is for the relief of shock, burns or neuroses. In cases of profound injury, and even where death has apparently occurred, prolonged artificial respiration should be maintained, as in drowning cases, with compression of the chest-wall in the precordial region; even digital compression of the heart itself has been proposed, but never successfully practiced. Crile recommends rhythmic pressure over the heart area, the tongue being drawn out, as he says that this combines circulatory and respiratory artificial stimulation.

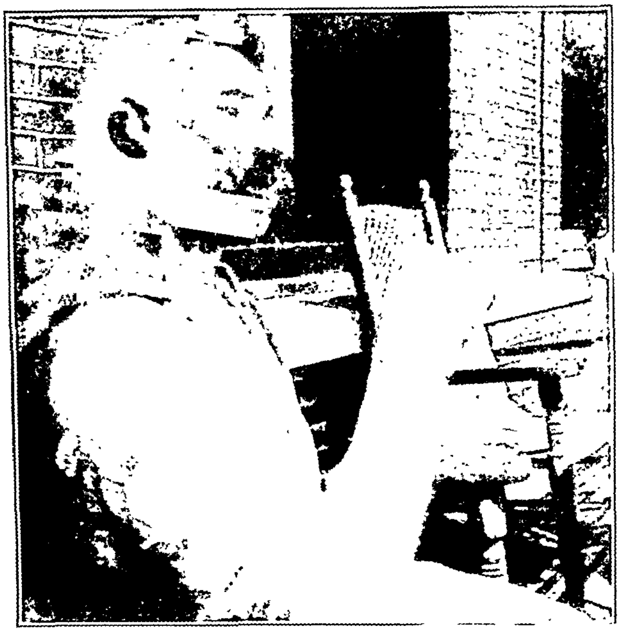

Fig. 1.—Example of third-rail burn.

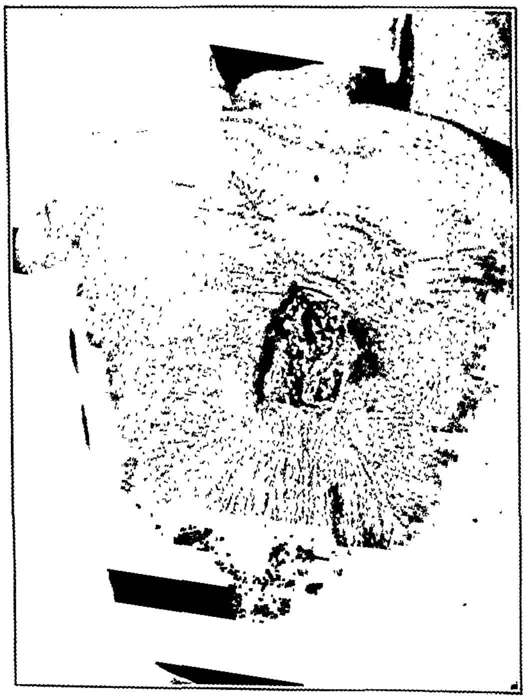

Fig. 3.—Third degree electric burn extending from mid-scapular to lower lumbar region.

With the foregoing manual methods, the use of various stimulants of the atropin, strychnin and adrenalin sort is also advisable.

Burns are treated in accordance with the custom of the individual physician, and it has been observed that the so-called open method of treatment is especially efficacious in this type of burn.

Neuroses are best treated by isolation, plus the mental or therapeutic means best liked by the individual practitioner.

PROGNOSIS

Prognosis depends on the extent of initial inhibition symptoms; in patients that survive forty-eight hours, the prognosis is that of the absorption of septic and toxic products from the burned areas, with the development of cardiac, respiratory or kidney complications, and with, occasionally, the presence of fatal gastro-intestinal disturbances.

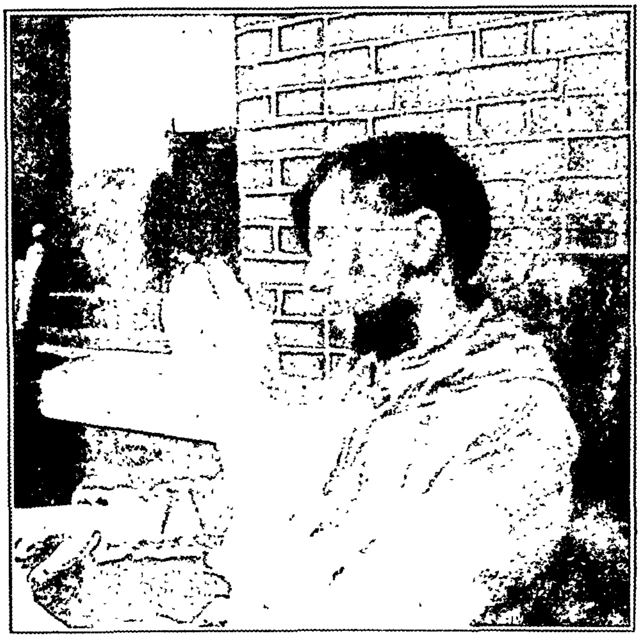

Fig 2.—Example of third-rail burn.

The ultimate scarring and contraction from the burns requires no comment. Neuroses do not ordinarily develop until after the patient has recovered from the main objective symptoms, and these nervous manifestations then frequently stand in relationship to a pending claim, and recovery does not usually ensue until adjustment is effected.

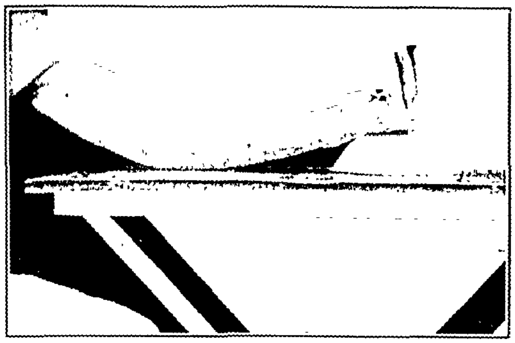

Fig. 4.—Pseudo-Dupuytren's contraction as the result of electric burn, showing marked palmar flexion at the metacarpo-phalangeal joints of the inner four fingers.

CONCLUSIONS

It can be stated that there is no special form of physical effect inherent to electricity inasmuch as every symptom can be paralleled by other forms of trauma. Likewise there is nothing pathognomonic in electric shock and the symptoms of it are those common to other forms of systemic shock, with or without burns or neuroses. The duration of symptoms is no more prolonged after electric than other forms of trauma; nor does there appear to be any sound basis for the claim that one electric shock renders the recipient more prone to similar experiences, but on the contrary an acquired immunity seems to be created by repeated applications. Electricity is well understood scientifically and is governed by well-known physical laws, and there is no good reason for the view often expressed that its effects on the human economy are unusual or peculiar.

THE SURGERY OF THE HYPOPHYSIS FROM THE STANDPOINT OF THE RHINOLOGIST

J. MONTGOMERY WEST, M.D.
Assistant Laryngologist, Johns Hopkins Hospital
BALTIMORE

Heretofore rhinologists have been interested in the hypophysis only in a general way. Like others, they have been watching intently the results of the researches which are gradually unraveling the mystery enveloping the physiology of this gland, but up to the present time they have given but scant attention to the surgery of this structure. The explanation of the apparent lack of interest in the surgery of this region is to be sought in the fact that cases requiring operations on the pituitary body are never seen by rhinologists, and hence the nasal surgeon has never considered the hypophysis, although practically an extracranial structure, as being within the field of nasal surgery. Once the rhinologist's attention is directed to this region, however, he sees that he is in a position to help solve the problems of the surgery of this organ. The removal of the anterior wall of the sphenoid sinus through the nostril involves a technic with which the rhinologist has for years been entirely familiar. The anterior wall being removed, he has but to lengthen and to modify his instruments and he is in a position to attack the superior wall[1] separating the sinus from the sella turcica containing the pituitary body (Fig. 1).

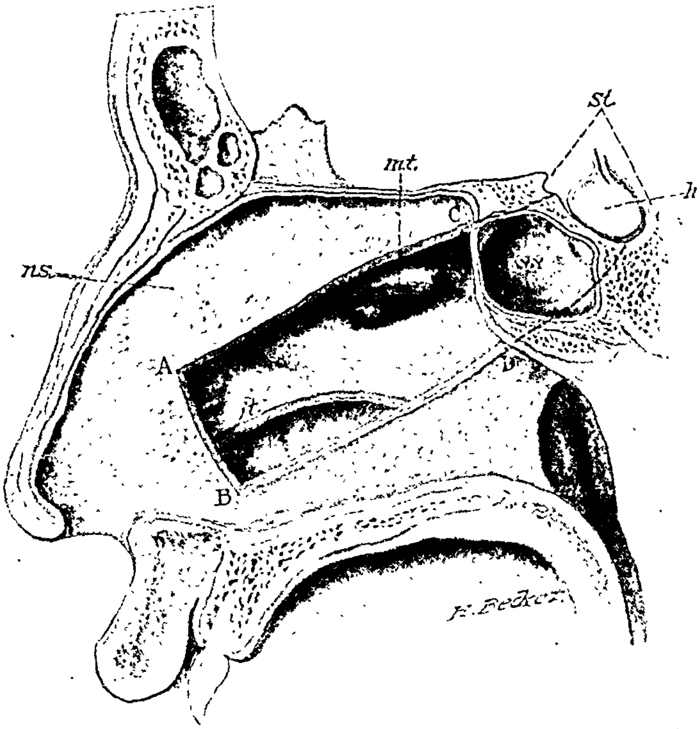

Fig. 1.—ABCD represents the window formed by resecting a quadrilateral piece from the nasal septum, N. S.; through this window the insertion of the removed middle turbinate is seen at M. T.; I. T., the remaining part of the inferior turbinate. AC and BD, continued by dotted lines, show the direction of approach through the sphenoid sinus, S. S., to the sella turcia S. T. containing the hypophysis, *H*. *For the sake of* clearness the anterior wall CD of the sphenoid sinus is shown, although in the operation it is removed before the nasal septum is attacked.

My interest was first awakened in this subject in February, 1909, through a case shown by Cushing before the Johns Hopkins Hospital Medical Society. In this case Cushing had successfully operated on the hypophysis by the supranasal method, that is through the superior part of the nose following a course parallel to the cribriform plate.

The methods of approach to the hypophysis, which had up to that time been suggested, were many, some more or less similar, and several were of a very mutilating character. Without attempting to describe in detail the difference between the various procedures, it may be noted that the methods may be classified according to Schloffer[2] as (1) *intracranial* and (2) *extracranial*.

1. Of the intracranial methods, aside from minor modifications, two entirely different procedures have been suggested:

A. *The approach through the temporal region of the skull*, lifting the temporosphenoidal lobe and thus reaching the hypophysis. This method, first suggested by Caton and Paul,[3] has been followed by Horsley[4] and McArthur.

B. The approach through the frontal bone, avoiding the frontal sinuses, lifting the frontal lobe and following the anterior fossa (Kiliani,[5] Krause[6]).

2. *The extracranial methods are those by which the* sella turcica is approached through the sphenoid sinuses, as, for example, by removal of the palate, and the interior of the nose (König[7]); or, as suggested by Kocher,[8] the superior maxilla is chiseled through above the alveolar process, and after incision of the soft parts a *Wangennasenlappen* is turned down and out; or after the nasal walls of the maxillary sinuses have been removed, through the fossa canina, Löwe[9] suggests making a skin incision along the nose which permits of a radical opening up of all the nasal sinuses by an anterior approach. Schloffer[10] in one case has turned the nose to one side, and, following a course parallel to the cribriform plate, after removing the turbinates and the nasal wall of the orbit, has succeeded in removing a tumor from the sella turcica. This method of Schloffer has been followed by Eiselsberg[11] in five cases and a similar operation has been done once in this country by Cushing.

It will be noticed that all of these operations are more or less extensive and necessitate great destruction of tissue.

Schüller[12] and Erdheim have pointed out the great value of the *x*-ray in aiding us to judge of the size of an hypophyseal tumor, and Schloffer's pathologic studies lead him to the conclusion that, so long as the cranial entrance to the sella turcica is enlarged to a diameter not greater than 2 cm., the tumor is operable by the transphenoidal route. Moreover, owing to the proximity of the carotids and the cavernous sinuses, the window which is resected from the sella turcica must necessarily be of small size, and hence all solid tumors operable by this route will be small. Large tumors of the pituitary region will probably all be inoperable.

---

[1] In speaking of the part of the wall of the sphenoid sinus which separates the sinus from the sella turcica, as the superior wall, we follow the description of Zuckerkandl (Anatomie der Nasenhöhle, Edition 2, Vienna, 1893, i, 335).

[2] Schloffer: Beitr. z. klin. Chir., 1906, l, 767.

[3] Caton and Paul: Brit. Med. Jour., 1893, p. 1421.

[4] Horsley: Brit. Med. Jour., 1906, ii, 44.

[5] Kiliani: Ann. Surg., 1904, No. 40, p. 35.

[6] Krause: Die deutsche Klinik am Eingange des 20 Jahrhunderts, 1905, viii, 1004.

[7] König: Berl. klin. Wchnschr., 1900, No. 46, p. 1040.

[8] Kocher: Operationslehre, 1902, Edition 4, p. 133.

[9] Löwe: Zur Chirurgie der Nase, Berlin, 1905.

[10] Schloffer: Wien. klin. Wchnschr., 1907, No. 21, p. 621.

[11] Eiselsberg: Wien. klin. Wchnschr., 1909, No. 8, p. 287.

[12] Schüller: Die Schädelbasis im Röntgenbilde, Fortschr. a. d. Geb. d. Röntgenstr., Ergänzungsband 11.

Considering, then, the fact that perhaps all operable tumors of this region will be small, it occurred to me that a conservative surgical method following a transnasal route diagonally through the nose roughly parallel to Zuckerkandl's line from the nostril to the sphenoid sinus ought to accomplish the same result as the more radical procedures. The following facts support this conclusion:

1. Adrenalin, owing to its constricting effect on the cavernous tissue of the nose, renders the nasal passages so patent that, in most cases, the anterior walls of the sphenoid sinuses can be clearly seen over a considerable area by inspection through the nostril. This being the case it would seem rational to follow this open route from the nostril through the sphenoid cavity, and by thus utilizing the space offered by the natural passages through the nose one is enabled to open the sella turcica with the *least possible destruction of tissue.*

2. Without entering into the question of the physiology of the hypophysis, it will suffice to say that the researches of Howell[13] and of Schäffer[14] have shown that this organ has a definite physiologic function, and, while the experiments of Friedman and Maass[15] have apparently shown that in cats the pituitary body can, without injury to the animal, be removed, on the other hand, Paulesco[16] and also Cushing[17] have demonstrated that in dogs part at least of the anterior lobe is necessary to the life of the animal. The results of animal experiments cannot always be applied unchanged to human beings, and, besides, the complete extirpation of the hypophysis has apparently in man been accomplished in several cases without a fatal result. With the evidence at hand, however, the question of partial removal comes up at once. A glance at Figure 1 will show that this infranasal route, anatomically considered, would seem to be advantageous particularly for partial removal, for in this case the hypophysis is approached from below, making it easier to remove the posterior lobe than if the supranasal route parallel to the cribriform plate be followed.

3. The nasal surgeon, as mentioned above, had already developed the technic of this operation to the point of opening up the sphenoid sinuses, and it would seem but an easy and natural step to cross the sphenoid cavity and attack the sella turcica.

4. While in conditions demanding operation on the hypophysis the question of the cosmetic result is of minor importance, still, other things being equal, the procedure causing the least disfigurement should be the method of choice. In some of Eiselsberg's cases healing was accompanied by marked deformity. This infranasal method should be followed by no deformity at all.

With these facts clearly in mind I began on fresh cadavers to develop a technical method for this operation, which up to that time had not been suggested. In one of my early experiments, after resection of the middle turbinate, part of the inferior turbinate and the anterior wall of the sphenoid sinus of *one nasal cavity* alone, it was possible to remove the pituitary gland through the nostril without cutting the ala and with the nasal septum intact. This case represents, of course, unusually favorable conditions, and in my other experiments it was always necessary to remove part of the nasal septum, including the septum sphenoidale. Later as routine I began removing both middle turbinates, for this shortens the operation considerably. I followed in each case the general course here described, that is, in the direction of Zuckerkandl's line through the sphenoid sinus to the sella turcica. As each new difficulty arose I have tried to devise instruments to overcome it. Meanwhile Kanavel[18] of Chicago published an article describing a method of approach similar to that which I had been following. He is more radical, however, and advocates elevating the nose. I have developed the technic further than Kanavel has done, and am describing the procedure as I have developed it.

Fig. 2.—Chisel with knobs at either corner of the cutting edge used in removing the quadrilateral piece from the nasal septum. These knobs straddle the septum and prevent the chisel from slipping into the nasal cavity.

In the first place I suggest with Moskowicz[19] that the operation be done in two stages. I believe, however, the turbinates of both nasal cavities, the anterior wall of the sphenoid sinuses, part of the nasal septum, including the septum sphenoidale, can in most cases be removed at a preliminary operation with *local anesthesia* (cocain, adrenalin) without slitting the ala nasi at all. It will probably be a question entirely of the patient's tolerance for cocain and adrenalin; and it is suggested that in the cocainization particular attention be given to the regions of the foramina through which the nerves enter the nose, that is, the ethmoid and the sphenopalatine foramina. By observing this precaution one should be able to produce the necessary anesthesia with the minimum amount of cocain. This preliminary operation will technically always be best carried out, I am inclined to think, if done by the nasal surgeon.

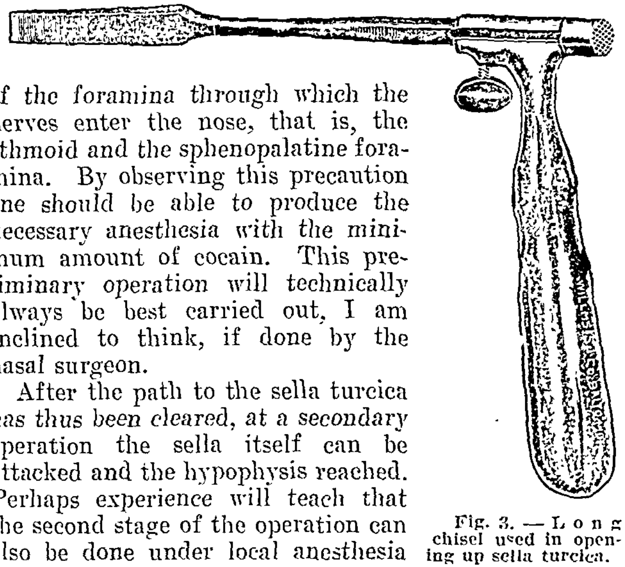

Fig. 3. — Long chisel used in opening up sella turcica.

After the path to the sella turcica has thus been cleared, at a secondary operation the sella itself can be attacked and the hypophysis reached. Perhaps experience will teach that the second stage of the operation can also be done under local anesthesia with cocain. Indeed, it may be shown in practice that it is possible, in some cases at least, to do the complete operation, that is both stages, as here suggested, with local anesthesia at a single sitting. For the second stage I recommend slitting the ala, although I have not found it necessary in any of my experiments on cadavers. Whether this second stage of

the operation should come within the field of the nasal or the brain surgeon remains for the future to decide.

The technic in detail is the following:

1. The middle and as much as is necessary of the inferior turbinate of one nasal cavity are removed to permit a clear view of the anterior wall of the sphenoid sinus. The anterior wall of the sinus is then removed. The instruments used are familiar to all nasal surgeons and need no special description.

2. This procedure is repeated in the opposite nasal cavity, reserving the septum to be attacked later. The partial resection of the nasal septum is postponed until after the removal of the turbinates of both nasal cavities, on account of the hemorrhage often met during operations on the vomer.

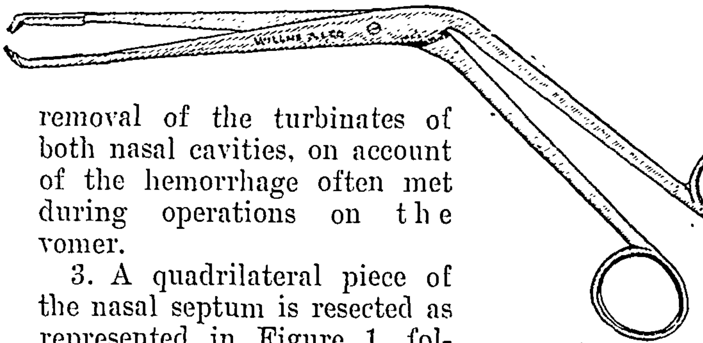

Fig. 4.—A long forceps with teeth set at an angle, used in removing pieces of bone from the sella turcica.

3. A quadrilateral piece of the nasal septum is resected as represented in Figure 1, following roughly Zuckerkandl's line in the direction of the rostrum sphenoidale. After this the septum sphenoidale is removed.

In attacking the nasal septum it is advantageous to begin by making an incision with a knife along the line A B (Fig. 1), then with a chisel (Fig. 2) cut, following the line A C to the sphenoid. Continuing with the chisel make a similar cut along the line B D, parallel to A C. This quadrilateral section of the septum is now removed in one piece, using for this purpose the Jansen forceps designed for the submucous resection of the nasal septum. The chisel (Fig. 2) used on the nasal septum is provided with knobs at either corner of the cutting edge which prevent it from slipping into the nasal cavity as it glides along the septum. (In cases of marked deviation of the septum this structure is then, of course, attacked as the second step of the operation.)

4. The septum sphenoidale is now removed partly with a long chisel (Fig. 3) and partly with a Grünwald nasal forceps. In practice it may be found to be helpful to note accurately the position of the sphenoidal septum with reference to the median line, and then to leave a slight ridge of septal bone to act as a guide to the midline at the secondary operation.

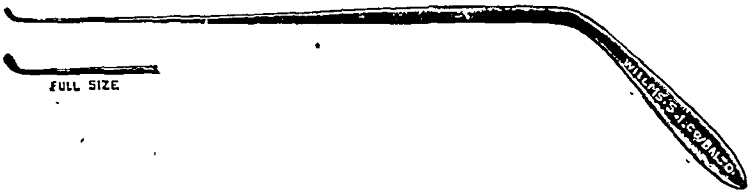

Fig. 5.—An extra long sound made of tempered steel which is often used to advantage.

5. The sella turcica is now opened up with the chisel (Fig. 3), the splinters of the bone being removed with the toothed forceps (Fig. 4). A long sound (Fig. 5) is often used to advantage.

In carrying out this fifth step, that is, the second stage of the operation as here proposed, the importance of keeping in the mid-line so as to avoid the optic nerves and the carotids cannot be too strongly emphasized.

It should be noted that Crowe's work showing the inhibitory effect of hexamethylenamin on infections of the meninges will make the rhinologist bolder in opening up the cranium from the nose.

To develop the technic for this operation, I have experimented on eleven cadavers. Owing, however, to the uncertainty of autopsy material and to the delays incident on devising and modifying instruments, the work (begun early in June, 1909) has extended over a period of six months.

For illumination of the field of operation I have used an ordinary gas-jet and a head-mirror such as belongs to the routine equipment of the nasal surgeon. A dilating speculum with an electric lamp attached at the distal end might be of assistance to surgeons who are not familiar with intranasal technic.

In suggesting that such an extensive intranasal operation be attempted under local anesthesia, one cannot but feel grateful to two men whose work has made possible, in the large majority of cases at least, both painless and bloodless nasal surgery. I refer to Koller, who first made use of cocain as an anesthetic, and to J. J. Abel, whose researches stimulated the work which culminated in the making of the adrenalin preparations as now used in practice.

Finally, I am much indebted to Dr. Whipple, of the pathological department of the Johns Hopkins Hospital, who kindly furnished the material for these experiments, and I desire also to express my appreciation of the assistance of Dr. Parsons and Dr. Brülle.

SUMMARY

In a word, this method is conservative and consists in approaching the sella turcica from below, following a course diagonally through the nose from the nostril to the sphenoid sinus, removing as much as is necessary of the turbinates, the entire anterior walls of the sphenoid sinuses, a quadrilateral piece from the nasal septum, including the septum sphenoidale, and finally attacking the sella. This procedure takes advantage of the natural space afforded by the nasal passages, and thus permits the sella turcica to be opened up with the *least possible destruction of tissue*. Further, I believe that the greater part of this operation can be done under *local anesthesia*.

A NEW APPARATUS FOR PROCTOCLYSIS

ANGUS McLEAN, M.D.
DETROIT

This apparatus consists of a galvanized iron or tin box (size 7 by 8 by 9 inches), the walls, floor and cover of which are made of two layers, between which is placed a sheet of asbestos to minimize heat radiation. For the front, two layers of glass instead of metal are used.

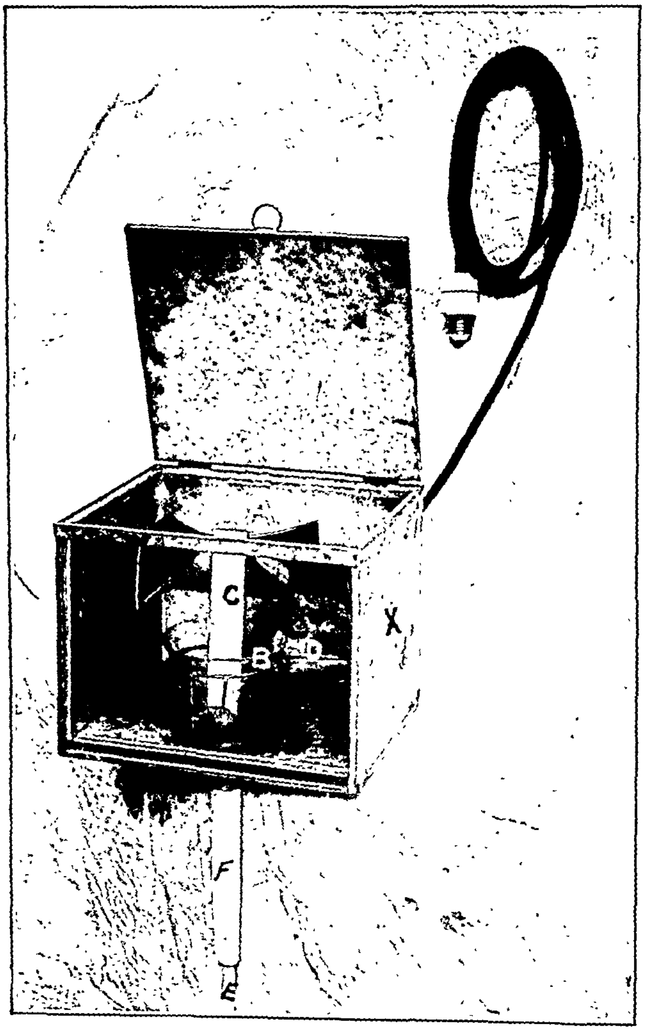
In this box are placed a two-quart dish (A), a funnel (B), a strip of gauze (C) and an incandescent bulb (D).

A. The two-quart dish is for the saline solution. The peculiar shape seen in the illustration is used to economize space. It is made as broad and as shallow as possible to insure a uniform drop.

B. The funnel receives the saline solution drop by drop and is connected with a tube (E) which leads to the patient's rectum. The tube leading to the rectum is enclosed in one (F) of larger caliber. This is attached to the floor of the box, but does not communicate with its interior. The purpose of tube F is to prevent radiation of heat from the inner tube, thereby conserving the heat in the saline fluid during transit from the container to the rectum.

C. The gauze hangs over a spout on the dish, and by capillary attraction causes the saline solution to flow drop by drop into the funnel and thence into the rectum. It is so arranged that the distal end hangs about 2 inches below the lowest level of the dish. A strip is used 1 inch wide and of varying thickness, depending on the number of drops per minute required (four-ply giving 50 drops a minute).

D. An incandescent bulb (or, if electricity is not at hand, an alcohol lamp) is placed under the dish and as near as possible to the double glass front in order to prevent condensation of vapor. A sixteen-candle-power bulb is sufficient. This will keep the temperature of the saline solution at 140 to 145 F. indefinitely. This temperature I have found necessary to cause the solution to enter the rectum at a temperature of 100 to 101 F., for, in spite of the double tube and the drop falling through air heated to 140 F. the loss of heat from the dish to rectum, through a tube 4 to 5 feet long, is about 40 degrees. Were the smaller tube not enclosed by a tube of larger caliber the water would enter the rectum at about 96 F., and the slightest draught coming in contact with the single tube would bring the temperature of the fluid entering the rectum still lower (to 85 and 80 F.).



A new apparatus for proctoclysis; A, dish for saline solution; B, funnel which receives the solution drop by drop; C, gauze hanging from spout of dish A, and conducting solution into funnel B; D, electric bulb; E, tube leading to rectum; F, larger tube enclosing tube E.

From this description it is evident that no part of the tube is constricted and that consequently there is always a free communication between the rectum and funnel. The drop is formed outside of this communication. Should feces, pressure of the thighs on the tube or anything else cause an obstruction to the flow into the rectum, the solution will at once be seen filling the funnel. Gas forming in the rectum, having absolutely nothing to obstruct its passage outward, will readily bubble up through the tube. The box itself is so arranged that the funnel will be from 8 to 12 inches above the level of the patient's rectum. In case the rate of absorption is slower than the rate at which the solution is dropping, the tube will naturally become filled with water. Even then, gas that may accumulate in the rectum, being much lighter than water, will easily bubble up through the tube. The amount of pressure necessary to bring about this result is that equal to 30 mm. of mercury, and pressure to that extent any patient can conveniently bear. Again, if the rate of absorption is slower than the rate at which the fluid is dropping into the funnel, say, 60 drops per minute, the fluid is running too fast for the individual. The rate of flow can then be diminished by simply using a strip of gauze with a lesser number of thicknesses. This will prevent the tube filling with water and consequently a pressure equal to 30 mm. of mercury, necessary to force gas through a column of water in the tube, will never exist. Gas will simply find its way through the patent, empty tube as soon as it is formed or, if it has been formed higher up in the colon, as soon as it reaches the rectum.

For the rectal end of the tube, the rectal tips advocated by Murphy are used.

This apparatus, therefore, furnishes a perfect drop which can easily be regulated to suit the needs of the patient. It allows for rapid expulsion of flatus. It is simple and very inexpensive (any tinsmith can make an outfit), and, if necessary, it can quickly be improvised in any household where a basin, a funnel, a tube and a piece of gauze are at hand.

57 West Fort Street.

A CASE OF HEMORRHAGIC PEMPHIGUS

CHARLES F. CLOWE, M.D.
SCHENECTADY, N. Y.

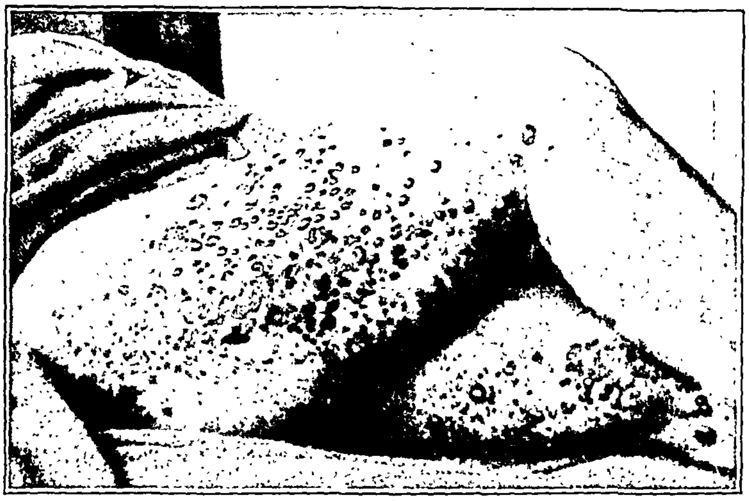
A case of pemphigus is rare enough to attract attention at any time, but a case of this degree of severity is so unusual as to merit reporting.

Patient.—J. McC., aged 29, driver of an ice wagon, a blonde, weighing 325 pounds, was admitted to my ward in the Ellis Hospital, Oct. 14, 1909, with the following history.

History.—His father died of tuberculosis at the age of 61. His mother, two sisters and a brother are alive and well. The patient had the usual diseases of childhood, pneumonia at 14, and gonorrhea at 22, of which latter he was "cured" in about six weeks. For the past two or three years he has had indefinite pains attributed to rheumatism. There is no evidence of syphilis. He is an excessive user of tobacco and at times drank heavily of both beer and whisky. For the past two years he has drank steadily, chiefly of beer. He suffers more or less from indigestion. His bowels move normally.

Present Illness.—Early in August, 1909, the patient noticed some blisters on the skin of the thighs and pubic region which itched somewhat. These dried and new ones came for the next three or four weeks, during which time he kept at work and felt fairly well, although he visited a physician and applied local treatment. During the month of September the eruption steadily increased and his strength and appetite failed, until about October 1, when he was obliged to give up work.

Examination.—He is an extremely large man. His body is almost covered with a bullous eruption, the blebs varying in size from a pea to the area of a half dollar. The eruption is most profuse on the thighs, in the axillæ, over the abdomen and neck. No part is free except the palms of the hands and soles of the feet. The blisters are seated on a slightly reddened base and filled with a clear serum. Many of them are tinged with blood. The character of the eruption is well shown in the accompanying illustration. His tongue is coated, there is complete anorexia, bowels are regular. He is delirious during the night and at times during the day, is hard to manage and vile in his language. His pulse was always relatively high and of poor quality. Tobacco and alcohol were both stopped on admission. A blood count showed whites 7,200, reds 4,320,000. On examination the serum in the blisters was found sterile.



Hemorrhagic pemphigus.

Treatment and Course.—The blebs were punctured, the fluid expressed and a dressing of very soft oxid of zinc ointment applied. He was given 5 m. of Fowler's solution and ½ ounce of linseed oil three times daily. The patient steadily improved and in about two weeks the eruption had entirely disappeared with no loss of tissue, and only a bright red stain remained. During this time, however, he developed a marked paresis of the extensors of the arms and legs accompanied by no pain, but a general muscular soreness. This gradually has cleared up under the use of strychnin and electricity until at this writing (Dec. 15, 1909), he is in very good condition.

613 Union Street.

A NEW APPARATUS FOR THE ESTIMATION OF BLOOD-PRESSURE

DELNO E. KERCHER, M.D.
PHILADELPHIA

The apparatus for the estimation of blood-pressure which I desire to present has the following features to recommend it:

Extreme simplicity; the avoidance of all ground joints, cocks, valves and complicated mechanisms.

Absence of metal parts to amalgamate the mercury.

Ease of manipulation; only one hand being required to work the apparatus, the other being free to feel the pulse or manipulate the stethoscope in auscultation.

Cheapness; there being no expensive parts or construction, this apparatus can be sold for one-half the price of the cheapest instrument at present on the market.

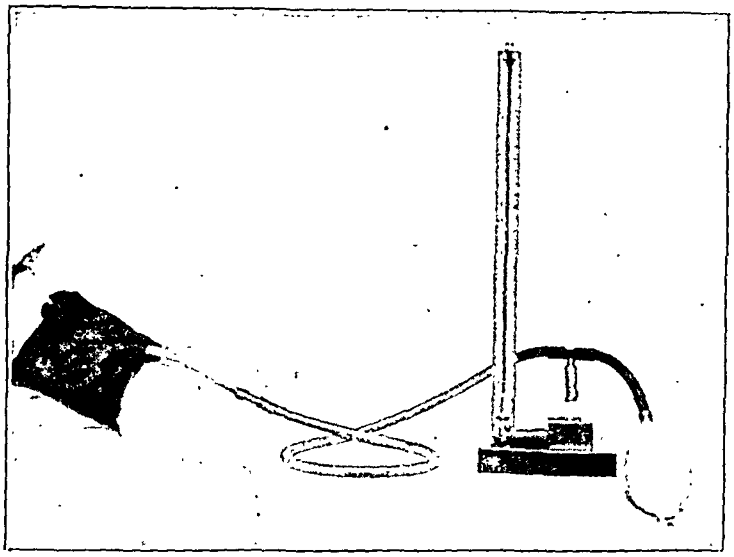
Portability; it may be taken apart readily, carried in any convenient bag and quickly put together again for use. The entire apparatus weighs fourteen ounces.

This apparatus consists of:

1. Wooden base with supports for small glass mercury cistern and for upright 300 mm. scale graduated in millimeters. Lying in a groove in this scale is the glass tube containing the mercury column which measures the pressure.

2. A strong cloth cuff 4 by 36 inches, containing the rubber pneumatic tube.

3. Three feet of strong rubber tubing bearing at one end a slip connection for attachment to the pneumatic cuff, at the other a rubber bulb with double valve for applying the air pressure to the apparatus, and in the tubing about six inches from the bulb a T connection to attach the cuff and bulb to the mercury cistern.



Apparatus for estimation of blood-pressure.

4. One ounce of pure mercury.

1534 Pine Street.

COMBINED MOUTH GAG AND TONGUE FIXER AND SUCTION APPARATUS FOR TONSIL OPERATION

EDWARD C. SEWALL, M.D.
SAN FRANCISCO

An efficient mouth gag and tongue depressor which I have been using for over six years is shown in the accompanying illustration (Fig. 1). It is modeled on the style of the old Hartman mouth gag, but involves an entirely new principle, in that it has a spatula so curved that it fits over the dorsum of the tongue, reaching the base of the epiglottis. By the employment of force from behind forward the base of the tongue is pulled away from the pharyngeal wall and fixed there. This allows free breathing space for the patient, and also puts the pillars of the fauces on the stretch so that their separation from the tonsil is much facilitated.

Figure 2 represents an apparatus devised by myself and Dr. F. A. Hamlin which adds very materially to the safety and ease of doing a tonsil operation. It consists of a large bottle in which a partial vacuum is produced by means of a water suction pump. A column of mercury registers the "negative pressure." A tube is attached which is sterilizable and can be passed easily through the mouth or nose into the throat. The pump used is of large size and fits on an ordinary faucet. The bottle exhausts quickly and, being of large size, retains its efficiency for a considerable period. This apparatus can be set up in any operating room at nominal cost.

A little experience in the use of the gag and tongue fixer is important, and a few words are pertinent as to the method employed in the Cooper College Clinic, where the apparatus has been developed.

The gag and tongue fixer is used usually with a general anesthetic, no gag being necessary where local anesthesia is employed. The patient invariably is given ether with the Allison inhaler, usually preceded by nitrous oxid. The recumbent position with overhanging head is employed. When the patient is anesthetized, a tube is passed through the nose and the ether given by the Bottsford-Junker apparatus. This usually produces some irritation, accumulation of mucus and coughing. It is here that the gag is of use. Such accumulation of mucus in the throat of anesthetized patients, especially where ether is used, is a source of danger. On introducing the gag and tongue fixer the breathing is immediately free except for the presence of the mucus, and this is then easily removed by slipping the tube of the suction apparatus into the throat. Such a method is recommended whenever in giving an anesthetic for any purpose there is liability of aspirating mucus. It is more efficient and in all ways preferable to the unsatisfactory method of wiping out the throat.

In the introduction of the gag, on account of the curve of the tongue fixer, it is sometimes necessary to bend the head backward in order to get it over the tongue. The blade is adjustable and should reach to the epiglottis. The mouth is then opened by pressing the thumb piece and held by the ratchet. The part of the ring resting on the teeth is so bent that it is suitable for infant or adult mouths. One point of great importance in the use of the gag is that the handle be raised by the anesthetist so that the gag fulfill its object, i. e., the bringing forward of the base of the tongue.

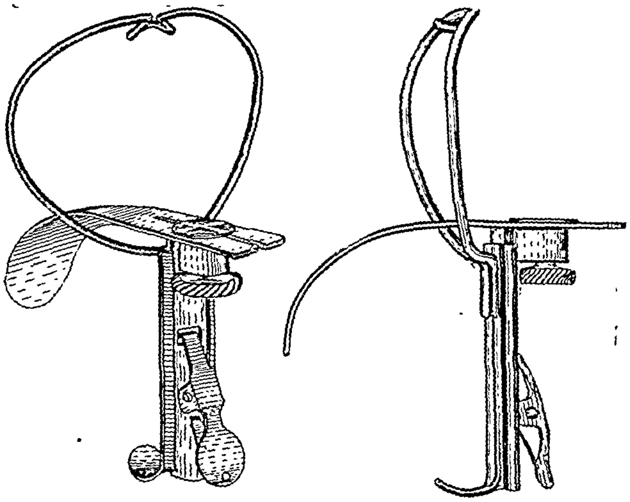


Fig. 1.—Combined mouth gag and tongue fixer.

The mouth is now open, the tongue fixed away from the field of operation, the breathing is undisturbed and there is no possibility of aspiration of mucus or blood. The overhanging head allows all the latter to flow toward the nasopharynx, where it is quickly aspirated by the suction apparatus. The pillars are drawn taut and the fold of the anterior pillar running to the base of the tongue engages the separating knife readily. The tonsils are removed in their entirety.

I wish to recommend the gag and tongue fixer especially in relation to the hemorrhage that may occur in tonsil operations. It must be admitted that, though the tonsil with its capsule is removed, leaving the superior constrictor bare, this does not do away with all danger of hemorrhage. Where hemorrhage occurs after the patient has recovered from the anesthetic, the usual means of stopping it are first employed. If these fail, the gag and aspirator make it possible to again fix the parts and clean the field. Where readministration of an anesthetic is for some reason undesirable, the patient may be held by force and the gag introduced. He has no control over his tongue or throat, no matter how he may gag or struggle, and any vomitus which may appear is aspirated.

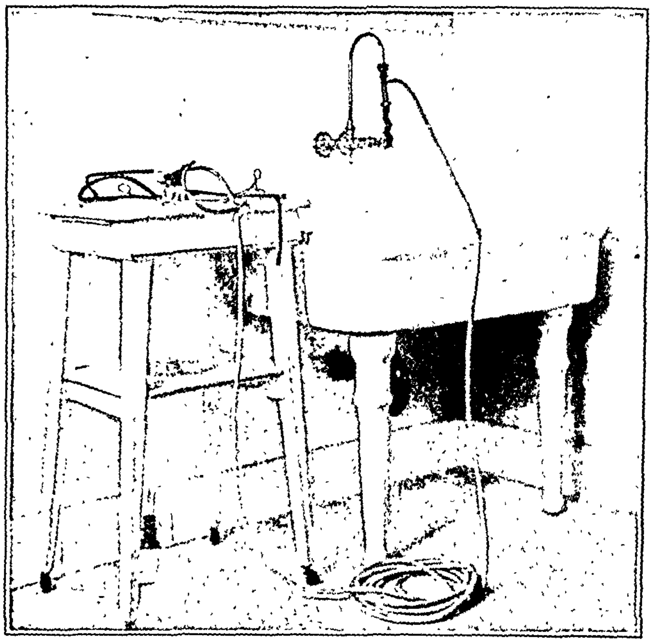

Fig. 2.—Suction apparatus used in tonsil operations.

The amount of blood lost in this operation by children especially is important. For that reason the bottle has been graduated in ounces and thus the exact amount of blood lost can be measured. If any simple antiseptic solution is used in cleansing the tube the amount of this is deducted from the total amount of fluid in the bottle.

This gag and tongue fixer is manufactured by H. Weniger, 244 Ash Avenue, San Francisco.

135 Stockton Street.

EPIDERMIDOLYSIS BULLOSA CONGENITA

(EPIDERMOLYSIS BULLOSA HEREDITARIA OF KÖBNER)

J. PHILLIP KANOKY, M.D.
AND
RICHARD L. SUTTON, M.D.
KANSAS CITY, MO.

Since Tilbury Fox,[1] in 1879, described two cases of "congenital ulceration of the skin, with pemphigus eruption and the arrest of development generally," and Goldscheider,[2] in 1882, reported his peculiar example of "acantholysis," about 100 cases of the novel affection from which their patients suffered have been placed on record. In addition to these, we desire to report the clinical history and the laboratory findings in a case of

---

1. Fox, Tilbury: Lancet, London, 1879, i, 766.
2. Goldscheider: Monatsh. f. prakt. Dermat., No. 6, 1882.

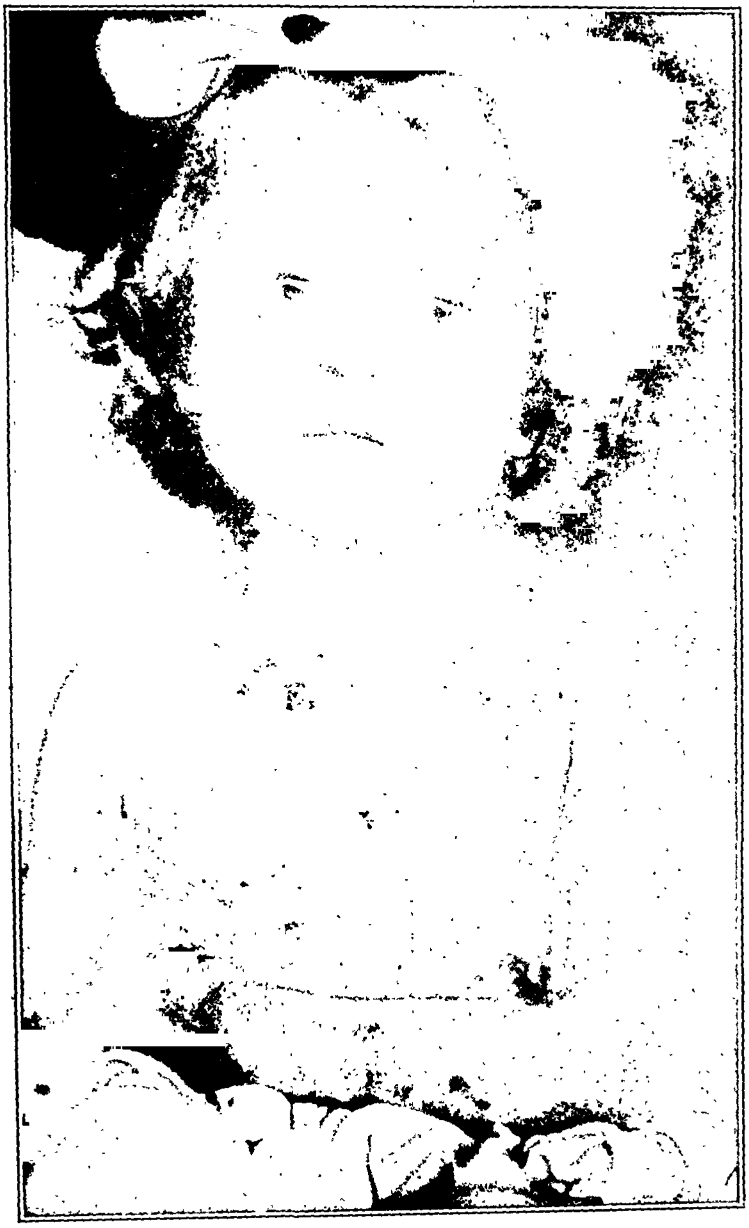

Fig. 1.—Showing ruptured and disappearing bullæ on trunk and arms.

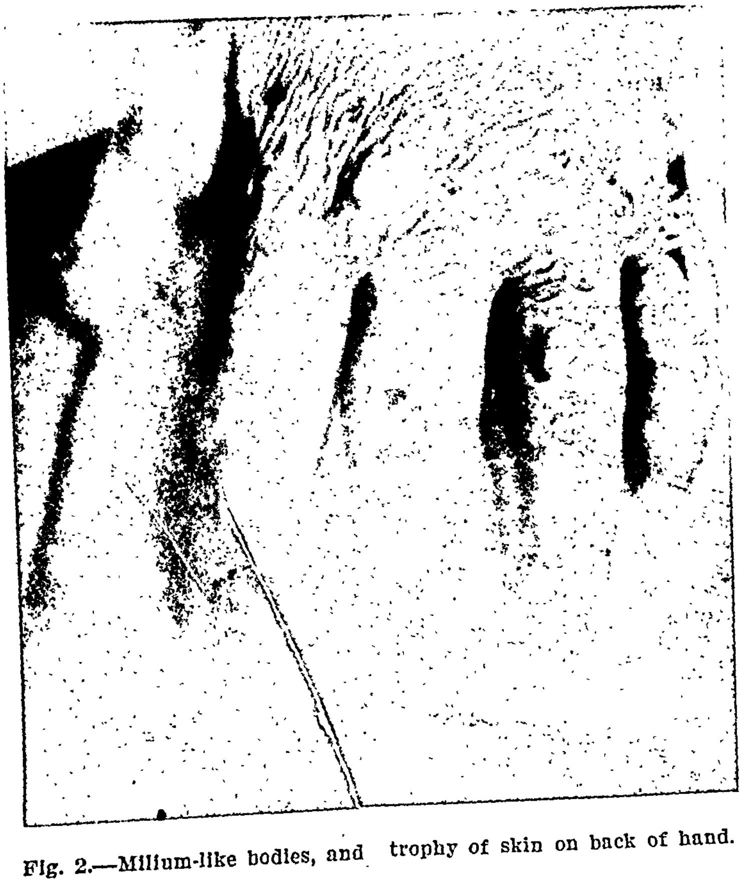

Fig. 2.—Milium-like bodies, and trophy of skin on back of hand.

epidermidolysis bullosa which has been under our care during the past five months.

Patient.—M. W., female, aged 3 years.

Family History.—The father is a farmer by occupation, and a strong, healthy man of 26. The mother is 22, has always enjoyed good health, and has never had a miscarriage. There is one other child, a boy, aged 5. His health is excellent. The cutaneous history of the family is negative. No other member has ever been affected with a similar disorder so far as the grandparents remember.

Personal History.—The patient has never experienced any illness other than the one for which relief is now sought. She was a nine-months baby, and the delivery was uncomplicated. At birth the skin and nails were apparently like those of any other child. The mother's health during the period of gestation was good.

Present Illness.—When the patient was two days old a large bulla appeared on the outer side of the left leg. No cause for it could be assigned. A few days later, she struck the back of her left hand on the side of the crib, and the slight injury resulted

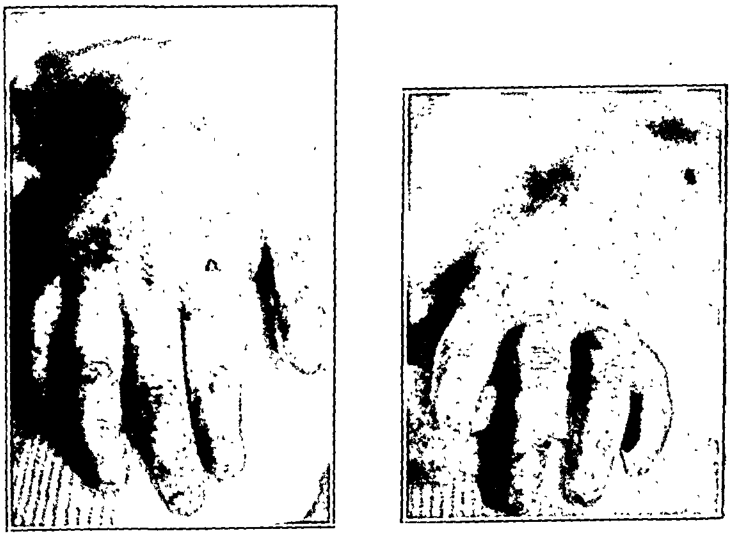

Fig. 3.—Showing atrophy of nails.

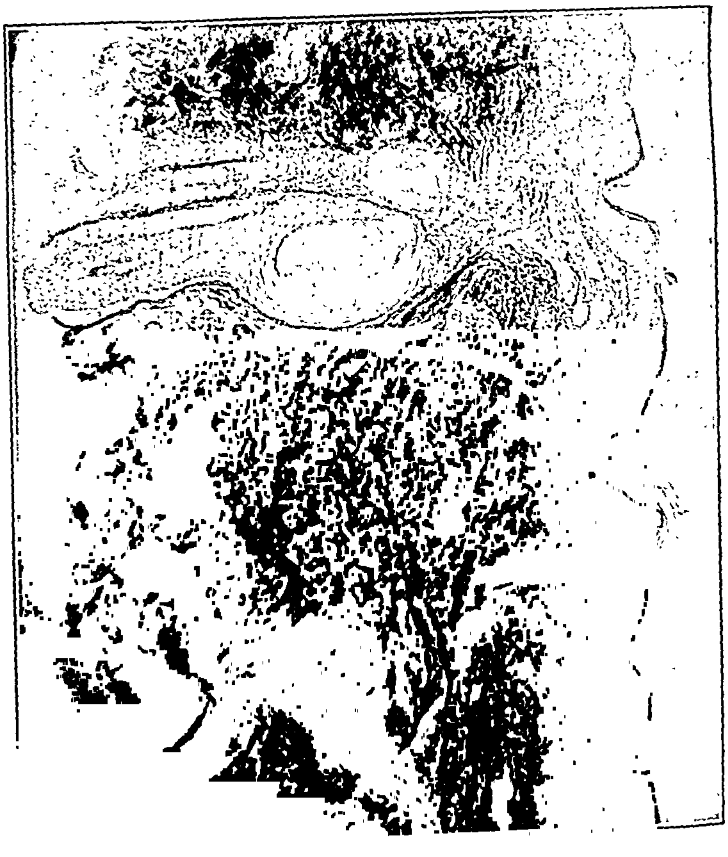

Fig. 4.—Section showing absence of elastic tissue in papillary and subpapillary regions and hair follicle.

in the development of a large hemorrhagic bleb one hour later. Since then the skin has never been entirely free from lesions. No part appears to be exempt. Vesicles have developed on the buccal mucous membrane frequently since the third month. As a result of repeated exfoliation, the finger nails have practically disappeared, and the toe nails have become atrophied and deformed. In consequence of injuries to the scalp, and the ensuing development of bullæ, several bald spots have appeared. The patient becomes cold easily, and often complains of chilliness when her brother is not suffering in the least. There has never been excessive sweating. The lesions are almost painless. They itch very little, and heal promptly. They form rather slowly—in from one-half hour to two hours after the receipt of the injury. Commonly they contain only serous fluid, but occasionally, following considerable injury, they are filled with blood.

Examination.—The patient is a well nourished child, a blonde, and rather large for her age. The hair is long and silky. There are three spots of cicatricial alopecia on the scalp. The teeth are normal. The buccal mucous membrane is paler and smoother than usual, and the tongue is partly bound down. The pharynx appears to be unaffected.

On the body and limbs are numerous lesions in various stages of development or subsidence. On the back of each hand is a considerable number (20 or more) epidermic cysts (minute, pale, flat or cup-topped elevations). In these localities the skin is thin, parchment-like and atrophic. Both palms are marked by the remains of recent bullæ. Friction with a rough towel produces blebs. The seats of former lesions are not wholly immune, but it is more difficult to produce bullæ here than on surfaces which have never been injured.

In four blood counts, made at intervals of one month, the highest number of whites found was 12,400, and the lowest, 6,800. An average of the four gave 39 per cent. polymorphonuclears, 41.2 per cent. small mononuclears, 11.2 per cent. large mononuclears and transitionals, and 8.6 per cent. eosinophils. The serum in the blebs contains very few eosinophils. Exposures to the *x*-rays, for from three to eight minutes, at a distance of 12 cm., a soft tube being used, invariably result in the production of bullæ (as in Berger's[3] case). The lesions heal within the usual period, and we have not found the areas thus treated any less liable to subsequent injury than those which have not been exposed to the rays.

Histopathology.—A piece of the uninjured integument, measuring 1 by 2.5 cm. was excised from the right upper arm under chloroform anesthesia. This material was cut in two, and one portion fixed in alcohol, the other in 10 per cent. aqueous solution of formalin. Later the formalin specimen was divided, and one-half mounted in celloidin, the other in paraffin. For comparison, sections of normal skin, taken, post-mortem, from the upper arm of a three-year-old child, were used, together with some material secured (also post-mortem) from the chest of a fifteen-year-old boy. The sections intended for study of the general structure were stained with hematoxylin-eosin. For elastic fibers Weigert's elastic tissue stain and Unna's orcein mixture were employed. In the hematoxylin-eosin sections the only changes observable in the horny layer are those which might occur as a result of acute edema. The cells are plumper and more rounded than normal, and those in the uppermost layers are less flattened than the ones in the fourth and fifth layers of the control. The outer (upper) portion of the section stains fairly well, but as the granular stratum is approached the coloring becomes faint and pale. The nuclei throughout stain very poorly. In the prickle-cell layer the interepithelial channels are widened and some of the fibrils are broken. There is some granular degeneration of the cells that constitute the lower part of the rete, and the nuclei stain irregularly. The interpapillary processes are swollen and edematous. The papillæ also are swollen, and the blood and lymph vessels are somewhat dilated, but there is no cellular infiltration. In the subpapillary region there are some lymphocytes and considerable numbers of connective tissue cells in the neighborhood of the vessels. The edema is less in the deeper regions, and there is little or no perivascular infiltration, but the vessels here also are dilated. Some of the coil glands are slightly affected. Their component cells stain irregularly, and the lower portions of the ducts are at some points blocked with cells, but there is no dilatation.

It is extremely probable, as Politzer[4] has suggested, that practically all of these changes occur as a result of injuries sustained by the skin during the performance of the biopsy. This also would account for the slight difference in the microscopic findings of various observers. But the fact that there must be a predisposition to injury on the part of the skin must also be taken into consideration. Until recently no plausible reason for this lack of resistance had been found. That it was due to some structural fault had been suggested by Payne,[11] Elliot,[5] Gilchrist,[6] Welch,[7] and others, but the exact nature of this peculiarity escaped the notice of a large number of careful investigators. It is when the stains for elastic tissue are used that this typical and, so far as we know, specific anatomic difference between the sections of normal skin and those of epidermidolysis bullosa is shown.

Stanislawski,[8] working in Podvisotski's laboratory at Odessa, was the first to note the absence of elastic tissue in the lesions of the affection, but, in spite of the fact that the excellent drawings with which his article is illustrated fail to show the presence of elastic fibers in the upper corium, he specifically states that this tissue was normal in the uninjured localities. Engman and Mook[9] pointed out that the elastic fibers were almost or entirely absent in the papillary and subpapillary regions of the derma in not only the bullæ, but in the apparently normal skin as well.

In the sections from our case scarcely a trace of this tissue is to be found in the upper corium. Below the subpapillary region the network is fairly heavy and regular, but as it passes upward it quickly shades off into a thin, friable-looking mesh which disappears practically altogether when the upper derma is reached. The fibers are entirely absent in the hair follicles as well, a fact which has not been noted by previous observers.

The controls show the thick, wavy fibrils running up into the papillæ, and passing into the mucous layer above, to finally terminate between the cells of the basal layer of the epidermis. We consider it extremely probable, as Pusey[10] suggests, that these prolongations of elastic tissue constitute an important factor in binding together the two major layers of the skin, and we believe that the almost complete absence of these fibers in this region in epidermidolysis bullosa undoubtedly explains the predisposition to injury manifested by the integument in cases of this affection.

Inasmuch as this condition is a congenital one in practically every instance, and hereditary in only about 50 per cent. of the cases, it appears to us that the term "epidermolysis bullosa congenita" is to be preferred to "epidermolysis bullosa hereditaria." Dr. Achilles Rose has kindly informed us, however, that the expression "epidermolysis" is incorrect, and that "epidermidolysis" is the proper word to employ. Although it may appear injudicious to suggest a new name for a disorder which has already suffered from over-christening, it is never too late to give an affection its proper designation, and so, in this instance, the title "epidermidolysis bullosa congenita" is used.

EXPERIMENTAL EPIDEMIC POLIOMYELITIS IN MONKEYS

SIXTH NOTE: CHARACTERISTIC ALTERATIONS OF THE CEREBROSPINAL FLUID AND ITS EARLY INFECTIVITY; INFECTION FROM HUMAN MESENTERIC LYMPH NODE *

SIMON FLEXNER, M.D., and PAUL A. LEWIS, M.D.
NEW YORK

In our last communication,[1] we pointed out that by making use of the filterable nature of the virus of epidemic poliomyelitis we had succeeded in detecting it in the nasal and pharyngeal mucosa of the monkey, from which we concluded that one path of elimination of the virus was by way of the nasal mucosa through its lymphatic connections with the pia arachnoid of the brain. On the basis of this observation, we assumed that infection in the monkey might be accomplished by the reverse route, namely, from the nasal and pharyngeal mucosa, and that this route probably represents one of those traversed by the virus in the course of spontaneous infection in man. We have made some experiments covering this point and have ascertained that when an emulsion of the spinal cord from a recently paralyzed monkey is brought into intimate contact with the scarified mucous membrane of the nose and pharynx infection results. In the protocol that follows, note should be taken of the location of the paralysis in the muscles of the upper half of the body.

Experiment 1.—March 15, 1910: *Macacus rhesus*, ether anesthesia; scarified nasal and pharyngeal mucosa; dropped a milky suspension of spinal cord into nose and rubbed it in gently with cotton pledget. March 18, reapplied same suspension. No immediate effect. March 21, 8 a. m., paralysis of muscles of neck and arms; legs strong but animal cannot stand; died during night of the same day.

In a recent publication,[2] we described the series of changes in the meninges which we believe precede the development of the vascular impediments that ultimately cause paralysis. We have followed the alterations which take place from day to day, following intracerebral inoculation of the filtrate, and have found them to be of rapid development and characteristic nature.

When a considerable dose of filtrate is injected, the cerebrospinal fluid secured twenty-four hours later by lumbar puncture is of normal quantity but contains a considerable number of small cells, hardly exceeding a lymphocyte in size but showing a polyform nucleus, a few lymphocytes, and some red corpuscles. At the expiration of forty-eight hours, the white cells have increased in numbers, but the cells with polyform nuclei still predominate. At the expiration of seventy-two hours, a large number of mononuclear cells have appeared and the fluid presents a striking opalescent appearance. On the day of paralysis, the fluid tends to be only slightly cloudy and contains a mixture of large and smaller (lymphoid) mononuclear cells, and a few cells with polymorphous nuclei.

The fluid withdrawn on the third day, which is several days in advance of the appearance of paralysis, contains the virus, and when injected intracerebrally it is capable of setting up paralysis in another monkey.

Experiment 2.—March 10, 1910: Inoculated *Macacus rhesus* intracerebrally, under ether anesthesia, with 1.5 c.c. of fluid obtained by lumbar puncture on third day after injection of filtrate. March 16, paralysis of left arm. March 17, paralysis of arms, legs and neck. March 21, died. Lesions characteristic.

These experiments show that the cellular changes in the meninges and cerebrospinal fluid begin immediately after the intracerebral injection of the filtrate and are thus present several days before the onset of the paralysis. Should this observation be confirmed for human beings, a valuable method of diagnosis of atypical and abortive or non-paralytic cases would be secured. An abrupt change in the nature of the cerebrospinal fluid, from being opalescent, rich in cells and spontaneously coagulable just before or at the time of paralysis, to a more limpid fluid, poorer in cells immediately after, often occurs. The spinal cord removed on the third day after an intracerebral injection shows beginning meningeal infiltration and normal vascular and nervous structures.

Through the kindness of Dr. W. T. Longcope of Philadelphia, we secured portions of the spinal cord and a mesenteric lymph node, preserved in glycerin, from a child of five years who had died on the fifth day of illness. The child was under the care of Drs. Marcy and Hodge. The symptoms were suggestive of infantile paralysis—onset sudden. Sections prepared from the spinal cord, kindly sent by Dr. Longcope, showed characteristic and extensive lesions of epidemic poliomyelitis.

Suspensions of the glycerinated spinal cord and mesenteric lymph node were each injected intracerebrally on March 8, into a monkey (*Macacus rhesus*). The animal inoculated with the spinal cord was well until March 19, when weakness and paralysis of the legs appeared. It was killed with ether. Characteristic microscopic lesions existed in the spinal cord. The monkey having received the suspension of the lymph node remained well until March 18, when paralysis of the legs and left arm appeared. Lumbar puncture yielded a faintly cloudy fluid containing an excess of mononuclear cells. The animal was killed with ether. Characteristic lesions were present throughout the spinal cord.

This experiment proves the virus of poliomyelitis is contained not only in the central nervous system but in mesenteric lymph glands, and suggests that it may be present in other organs in human subjects of the disease.

FORMALDEHYD POISONING

FRANK A. ELY, M.D.
DES MOINES, IA.

In view of the paucity of literature[1] on formaldehyd poisoning, the following case seems worthy of record:

The patient, a boy of 3 years, gained possession of a bottle containing a few drops of a 40 per cent. solution of formaldehyd which he tipped to his lips as though in the act of drinking. He was immediately seized with a paroxysm of coughing and choking, but the attack soon ceased. The child's mouth was rinsed out thoroughly with water and he was soon at play as if nothing had happened.

---

[1] References to the literature are given in The Journal, Jan. 29, 1910, liv, 370, and Jan. 15, 1910, liv, 221.

On the next day I was called and found the child suffering from a hoarse, laryngeal cough with accelerated and labored breathing. The pulse and temperature were normal and in every respect the child seemed to be in perfect health.

I made laryngeal application of adrenalin with temporary benefit. Inhalations of steam were advised and frequent teaspoonful doses of olive-oil were ordered to allay any pharyngeal or esophageal irritation.

Fifteen hours later I was called in great haste and found the child deeply cyanosed and showing every sign of laryngeal obstruction. I immediately transferred the patient to a hospital and called a specialist in consultation, hoping that intubation or tracheotomy might be performed and thus relieve the respiratory difficulty. Upon the arrival of the consultant, it was decided to defer operative procedures for the reason that we could not be at all sure that the obstruction did not extend low down in the trachea, in which case the introduction of a tube might produce an immediate fatal termination. Repeated applications of adrenalin were made and the breathing became somewhat easier, but during the night, eight hours after admission to the hospital, the child died.

Post-mortem examination, made six hours after death, showed a marked thickening of the mucous and submucous coats of the epiglottis, larynx and trachea, with a superficial necrosis which extended to the bifurcation of the trachea. The esophagus showed no pathologic changes, nor was there evidence of destruction of the mucosa of the mouth and pharynx.

The extensive thickening of the tracheal mucous membrane proved the wisdom of non-operative treatment because the morbid changes extended so low down that even a low tracheotomy would have failed to relieve the condition.

The points of greatest interest in this case are as follows:

1. The absence of systemic disturbance other than that produced by respiratory obstruction.
2. The absence of destructive changes in the buccal, pharyngeal and esophageal mucous membranes.
3. The extensive infiltration and necrosis of the tracheal mucosa extending below the point where a tracheotomy operation would be of value.

IODIN AS AN ASTRINGENT, ANTISEPTIC, DISINFECTANT AND GERMICIDE IN MOUTH DISEASES

EUGENE S. TALBOT, M.D., D.D.S.
CHICAGO

For an astringent, antiseptic, disinfectant and germicide in the mouth, there is nothing so convenient and quick acting as tincture iodin. I have used this drug as an astringent, antiseptic and disinfectant since 1878, but did not know of its germicidal properties until six years later, although I was obtaining the desired results of germ destruction.

Patients present themselves with fetor of the breath, pus about the teeth, inflamed gums, diseased alveolar processes, acid mucus and saliva, the latter being also ropy and stringy, plaques on the teeth and decay with all the forms of bacteria from the most harmless to the more dangerous pathogenic microorganisms such as the pneumococcus, diphtheria bacillus, tubercle bacillus and the germs of children's diseases. Miller has demonstrated more than fifty varieties of microorganisms in the mouth. Pus germs are often present in and about the necks of the teeth and easily infect wounds and inflamed tissue. These germs are also taken into the stomach at every swallow and some pass through into the intestines. While most of the better class of patients possess fairly cleanly mouths, yet from 12 to 20 per cent. of all patinets have pus germs in the oral cavity.

Tooth decay is due to lactic-acid ferment and nearly every person has it to a greater or less extent. Clinic and dispensary patients, and especially the poorer classes who never use brushes, washes or powders in the mouth, possess regular cesspools of filth. Before the fingers, even, are placed in such mouths, the mucous membrane, gums and teeth should be thoroughly painted—completely covered—with tincture of iodin. Enough iodin should be applied to run in between the gums and the teeth, and then it should be allowed to dry; afterward the mouth should be rinsed with water.

Attention was first called to this method of procedure by my researches on interstitial gingivitis. The pathology of this disease showed the inflammation to be deep-seated throughout the alveolar process. In order to reach this inflammation, iodin alone would penetrate the bone.

All people after the temporary teeth erupt have interstitial gingivitis more or less throughout life. The mouth of every patient of mine, therefore, who has any operation on the mouth or teeth, since I began this method, is treated to an iodin bath before or after the operation. This may occur every day, every other day or whenever the patient has an appointment.

The officinal tincture of iodin contains 7 per cent. of iodin dissolved in alcohol to which is added 5 per cent. of potassium iodid. This preparation, if used often will cause the mucous membrane to become tender and sore; it will also, in some patients, destroy the mucous surface. To overcome this difficulty, many years ago, I formulated the following, which I have called iodoglycerole:

Zinc iodid	15 parts
Water	10 parts
Iodin	25 parts
Glycerin	50 parts

The proportions were suggested by Prof. C. S. N. Hallberg of the University of Illinois School of Pharmacy, in order to obtain a clear preparation without deposits. As compared with the ordinary tincture of iodin, its astringent properties are greatly increased, the glycerin causes rapid absorption and the irritating effects are reduced to a minimum. The penetrating effect is remarkable. The glycerin thickens the preparation and prevents it from mixing with the saliva and running over the mouth as the ordinary tincture will do. Long, round, wood applicators can be obtained at the drug and instrument houses and on one end cotton is wound; this is saturated with the preparation and the gum margins above and below painted. The jaws are closed, the lips and cheeks distended and the application made as before, the teeth are also covered; the lips and cheeks are held away from the jaws until the iodin has dried.

No one drug will destroy lactic-acid bacilli and their ferment and thus stop tooth decay like iodin. Frequent applications will destroy all germs in the mouth and reduce mouth and general disease to a minimum.

Before operations on the mouth and fauces, the gums, teeth and mucous membrane should be given an application of iodin; especially in the removal of tonsils. After this treatment, and after the iodin has become absorbed, the tonsil or part to be operated on should receive similar treatment. This application should be made from 10 to 15 minutes before operation.

To prevent contagions and infections among public school children, their teeth, gums, and mucous membrane should be painted with iodoglycerole as often as once a month, during the school term. This method will greatly reduce tooth decay.

103 State Street.

New and Nonofficial Remedies

SINCE THE PUBLICATION OF THE BOOK "NEW AND NONOFFICIAL REMEDIES, 1910," THE FOLLOWING ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK ARE ASKED FOR.

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT SO FAR AS KNOWN IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

FILICIC ACID AND RELATED SUBSTANCES

Aspidium and pharmaceutical preparations thereof have long been used as teniafuges. The most recent work indicates that aspidium probably contains the following constituents, in approximately the amount indicated: Filicic acid, 3.5 per cent.; flavaspidic acid, 2.5 per cent.; albaspidin, 0.05 per cent.; aspidinol, 0.10 per cent.; flavaspidin, 0.10 per cent.; amorphous acid, 5.0 per cent. and filicic nigrine, 6.0 per cent. These substances are, for the greater part, derivatives of phloroglucinol, and some of them are ketones possessing acid characters.

The various formulas assigned to the filicic acids and the different results reported regarding their physiological activity, have given rise to much confusion, leaving the chemistry in an unsettled condition. One of the first formulas assigned to filicic acid is that of Luck—$C_{26}H_{30}O_9$, which differs considerably from the formula—$C_{14}H_{18}O_5$—given this substance by Grabowski and $C_{14}H_{16}O_5$, as suggested by Daccoma. Later two forms, a crystalline and an amorphous filicic acid, were recognized by Poulson, who suggested the formula, $C_{35}H_{40}O_{12}$ for the crystalline filicic acid and $C_{35}H_{42}O_{13}$ for the amorphous acid, which latter he considered as the active therapeutic principle of aspidium. Poulson believed the crystalline acid to be the anhydride of the amorphous acid. More recently, Gallas has stated the formula for both the crystalline and the amorphous filicic acid to be $C_{18}H_{22}O_6$. Gallas and later Kraft concluded that one form of the acid was the lactone of the other form. Filicinic acid, which has the formula ($C_8H_{10}O_3$) is sometimes confused with filicic acid. Besides a difference in the theories regarding the constitution of the various filicic acids, there has been considerable controversy over the anthelmintic properties of these substances.

Our knowledge of the subject is very imperfect, but the majority of authors still accept filicic acid as one of the active constituents of aspidium.

FILICIC ACID, AMORPHOUS.—Acidum Filicicum Amorphum.—Amorphous filicic acid is an organic acid $C_{35}H_{42}O_{13}$, obtained from several species of aspidium.

Amorphous filicic acid is a white, or yellowish powder, without odor or taste, melting at 125° C. (257° F.), soluble in cold alcohol.

Actions and Uses.—Amorphous filicic acid has been recommended as an anthelmintic, and is generally considered one of the active principles of several species of aspidium.

Dosage.—0.5-1.0 Gm. (8 to 15 grains) given with calomel or calomel and jalap.

Note:—The crystalline filicic acid, preferably desig- At the ex-
filicinic acid, which is considered as an anhy- the white cells have

d from the male fern extract by isolating
tallic salt. from which the free filmaron is
purified.

Filmaron occurs as a s
in water, difficultly solu
rather difficultly soluble in
in all proportions in ether
traw-colored amorphous powder, insoluble
ble in ethyl and methyl alcohols, and
petroleum ether. It is readily soluble
amyl alcohol, chloroform, benzene, carbon disulphide, and acetone, and also, though with partial decomposition, in solutions of the alkalies and alkali carbonates. The alcoholic solution exhibits a slightly acid reaction. Filmaron melts at about 60° C. (140° F.). It exhibits a strong tendency to cake together to form a resinous mass which is difficult to reduce to powder and dispense, hence it is not marketed in substance, but as a 10 per cent. castor oil solution, which is known as "Filmaron oil."

0.5 Gm. filmaron and 5 Gm. pumice stone, and 1 Gm. magnesia are finely triturated with 250 Cc. water, the mixture shaken for half an hour, and then filtered. On passing a rapid current of carbon dioxide through the filtrate, a voluminous, flocculent precipitate forms; the filtrate should afford but very slight precipitate on the addition of hydrochloric acid.

On dissolving 0.1 Gm. filmaron in 0.2 Gm. acetic ether or 0.2 Gm. carbon disulphide by rotation in a test tube, and setting the stoppered tube aside for three days, no separation should have taken place at the end of this time (absence of other male fern constituents; filicic acid and flavaspidinic acid).

0.1 Gm. filmaron should completely dissolve in 0.5 Gm. warm petroleum ether, and leave no more than a slight trace of undissolved substance. To detect the filmaron in the castor oil solution (filmaron oil), dilute the filmaron oil with ether, shake out with sodium hydroxide solution, acidulate the alkaline liquid, and then take up the liberated filmaron with ether. On evaporating the ether the filmaron is obtained as a residue.

Actions and Uses.—Filmaron is said to exhibit the specific action of male fern extract and to be useful as an anthelmintic for expelling intestinal parasites.

It is claimed to be devoid of the injurious side actions sometimes exhibited by the oleoresin of male fern and to be harmless when given in the dose necessary for the expulsion of tape worm.

Dosage.—See Filmaron Oil.

Manufactured by C. F. Boehringer & Soehne, Waldhof near Mannheim (Merck & Co., New York). U. S. trademark No. 40,558.

Filmaron Oil.—Filmaron oil is a 10 per cent. solution of Filmaron in castor oil.

Dosage: 10 Cc. (2½ fluidram).

(*To be continued*)

Therapeutics

CHOREA

Although the treatment of this disease is frequently discussed, its management is still too little understood, and the mistake of giving large doses of arsenic in the belief that, because the symptoms often abate during its administration, arsenic did it (it being forgotten that acute chorea is a self-limited disease) is still prevalent. Poisonous doses of arsenic can never be beneficial in chorea.

Dr. John Allan, of Edinburgh, Scotland, in the *American Journal of the Medical Sciences,* February, 1910, offers some valuable recommendations for the management of chorea. He well states that the most important factor in its successful treatment is more or less absolute rest and removal from all sources of frets and teasing which may occur when a child so afflicted, even mildly, is sent to school or allowed to associate with other children. Even if the disease is mild, the child should be put absolutely to bed, or at least should be put to bed several times during the day. From three to five weeks of bed rest and then two or three weeks of intermittent bed rest is the greatest promoter of quick recovery and
In view of prevention of cardiac complications. Hard
poisoning, the following case ercise, or even much walking, should

solution of formalin
playing or hard ex
be prohibited for some weeks after a
sufficiently to be about. During the period of rest in
bed massage should be administered daily, as soon as
there is no fever, and, of course, there may be no fever at
all. The massage should be more or less general, depending on its effect on the child.

More or less isolation of a choreic child is essential. Only those persons should come near the patient whose judgment is such as not to fret the child by their presence. When it is possible a sensible nurse is the best caretaker of the patient, as nervous, neurotic or fretted mothers are not the best nurses for these children.

The advantage of any particular specific diet is doubtful. The diet should depend on the acuteness of the symptoms or the amount of fever. If there is fever, the diet should be light but nutritious, perhaps mostly milk. If there is no fever, a sufficient, easily digestible, mixed diet, with perhaps meat in small amount only, is the best. Of course, tea, coffee, alcohol or any other excitants are prohibited.

It is essential that the bowels should be kept active in the manner found the pleasantest and the simplest, preferably with cascara or with phenolphthalein.

Warm baths every day or every other day, if the patient's movements are not too severe, are quieting and restful, and, with the massage, keep the skin in good condition.

In spite of the long-continued use of arsenic in chorea, it may be stated that there is no specific treatment for this disease. Those who advise the use of arsenic state that it must be rapidly pushed to the point of saturation of the tissues, i. e., to the point of tolerance. Some state that, if it does no good in the first two weeks, it will do no good at all. Others object to its use on account of the fact that in order to do good it must literally poison the patient; in other words, that the nervous system is more or less paralyzed by it if it inhibits the muscle movements in chorea. If given in small doses it probably is of little, if any, value, as when the disease becomes better it becomes better because it is time for the chorea to improve (it tending to recovery), but it does not recover on account of the small doses of arsenic. Arsenic pushed to rapid effect will frequently cause albuminuria and even nephritis, and casts and blood cells will be found in the urine. If the urine of every patient were studied daily during the administration of large doses of arsenic, less arsenic would be given. While small doses of arsenic in many anemic conditions (and in chorea the patients are often anemic) will stimulate the production of red blood corpuscles, large doses of arsenic will often cause destruction of red blood corpuscles.

Whether or not chorea is allied to rheumatism, Allan believes that acetyl-salicylic acid (aspirin) is a drug of great value in its treatment. He finds the best method of administering it to children is as follows:

℞.	gm. or c.c.		
Acidi acetyl-salicyli	8		ʒiiss
Acaciæ	q. s.	or	q. s.
Syrupi aurantii	25		fl.℥i
Aquæ chloroformi, ad	100		ad, fl.℥iv

M. et Sig.: A dessertspoonful, in water, every 4 hours. [This must be well shaken.]

This dose, he finds, is suitable for a child 6 years of age, but it should be increased as the child's age increases until at about puberty he gives from 90 to 120 grains a day. He says that acetyl-salicylic acid should never be given in tablets, and should not be prescribed with alkalies. He finds less symptoms of salicylism than occur from the salicylate of sodium and he does not find it depresses the heart. He quotes the German authorities as believing that acetyl-salicylic acid has an hypnotic as well as analgesic effect.

At times strong hypnotic drugs are required, and Allan prefers sulphonethylmethanum (trional), but some patients require stronger quieting drugs, as chloral and chloralamid.

If the heart is weak and a cardiac tonic is required, he prefers strophanthus in the form of the tincture.

As soon as convalescence is established, iron is certainly required. It may or may not be combined with small doses of arsenic. Of course, the acetyl-salicylic acid should be stopped as soon as the choreic movements have ceased.

It is needless to emphasize the necessity for removal or correction, as soon as possible, of any reflex irritation that may have caused or aggravated the chorea, be this intestinal worms, carious teeth, phimosis, clitoris adhesions, eyestrain, otitis media, or adenoids.

A patient who has recovered from an acute chorea should be given an outdoor, quiet life for several months. School work should be absolutely prohibited. If the chorea has occurred about puberty in young girls, all excitement and the strain of school life should generally be forbidden until menstruation is thoroughly and regularly established. Disturbances of menstruation are frequently the cause of chorea.

UNNECESSARY BLINDNESS

The caption of this article is copied from the *Journal of the Minnesota State Medical Association and the Northwestern Lancet* (February, 1910). The very association of these two words presents a truth that cannot be too frequently emphasized, and still, with all the discussion on the subject, it is not daily recognized that ophthalmia neonatorum, with its dire consequences, can and should be prevented. A symposium on ophthalmia neonatorum is presented in the above-mentioned journal, and ends with the following conclusions:

"1. The conjunctiva of the newly born is peculiarly liable to infection.

"2. Many germs may cause the infection, but the gonococcus is responsible for at least 65 per cent. of the cases and for nearly all of the severe infections.

"3. Ophthalmia neonatorum may almost surely be prevented.

"4. The 2-per-cent. silver nitrate is the surest prophylactic.

"5. The 1-per-cent. silver nitrate is nearly as valuable.

"6. Bichlorid of mercury, 1-2,000, is a good substitute and should be used if one has not the silver.

"7. If a prophylactic be used in the eyes of every newborn baby, the present rate of ophthalmia neonatorum will be greatly reduced.

"8. The treatment of the disease should always be turned over to the ophthalmologist."

Practical Applications of Salt in Epilepsy.—A. Ulrich has found that the symptoms of bromin poisoning rapidly subside when salt is given internally; the motor symptoms especially yield at once to the action of the salt. Even the *fetor ex ore* subsides under its influence. In his article on the subject in the *Neurologisches Centralblatt*, 1910, xvi, 74, he states that bromin acne is also rapidly cured by local application of a 10 per cent. salt solution. There seems to be no doubt, he says, that salt is the antidote to bromin. He also reports that he was able to bring on an epileptic seizure in 12 cases of genuine or Jacksonian epilepsy by giving 20 or 30 gm. of salt a day for a few days for diagnostic and therapeutic purposes. In one of the 3 cases reported in detail, the patient had had no severe seizure for several months and was in a condition of excitement bordering on mania. Administration of 30 gm. of salt on two successive mornings brought on a seizure after which the patient's mind was apparently normal. In another case the salt was given to disclose a possible epilepsy in a medicolegal case, and the findings were positive.

physiologic chemistry and comparative pathology, and the reorganization on new lines of the Henry Phipps Institute for the study, prevention and treatment of tuberculosis.

The Henry Phipps Institute is to be organized into three distinct lines of work—social, laboratory and clinical—and all these departments will be used to a more or less considerable extent in teaching medical students, and thus in spreading more widely knowledge concerning tuberculosis and the methods of attacking it. Generous financial provision has been made for the departments of research medicine and physiologic chemistry and for the Phipps Institute, the endowment for these three consisting of gifts aggregating $800,000.

The department of pathology will be in the hands of Dr. Howard T. Ricketts of the University of Chicago; the head of the department of pharmacology is not yet announced; the department of research medicine will be in the hands of Dr. Richard M. Pearce, now professor of pathology of the University and Bellevue Hospital Medical College, while Dr. Alonzo Englebert Taylor of the University of California will head the department of physiologic chemistry, and Dr. Allen J. Smith the new department of comparative pathology.

These extensive changes in the oldest medical school in the United States are sure to have a profound influence. They constitute another illustration of the present rapid development of medical education in this country.

SENATOR OWEN ADVOCATES A DEPARTMENT OF HEALTH

The declaration of President Taft at the University of Pennsylvania last year that "certainly the economy of the union of all health agencies of the National Government in one bureau or department is wise" bids fair to find expression in law. This is shown by the bill introduced by Senator Owen, providing for a Department of Public Health. In advocating the bill,[1] Senator Owen pleaded the law of precedent in accordance with which other departments have been created by assembling and coordinating pre-existing bureaus, and urged Congress to redeem the pledges on this subject made in the platforms of both the great political parties. He also pointed out the necessity of having a department with ample power, as the only means of conferring on the health agencies of the country such prestige and influence as would afford adequate protection to the people.

Senator Owen made some statements which tend to impeach the Department of the Treasury as a competent administrator of the health interests of the country. He stated that when he applied to the Surgeon-General of the Public Health and Marine-Hospital Service for certain information, he, a senator of the United States, could not get the information for two weeks or until the Secretary of the Treasury had returned to Washington. When the Surgeon-General finally made a statement to Senator Owen it was by express permission of the Assistant Secretary of the Treasury. This is an illustration of the humiliating status of our national health service under the existing system. It is true that until recently the Public Health and Marine-Hospital Service has been more distinctly autonomous than would seem to be indicated by the two foregoing incidents, but it was only by tolerance and not because the Secretary of the Treasury did not have the power at any time to subordinate that service by executive order. Nor can we reproach the Secretary of the Treasury. Central responsibility must carry with it central authority, and in national health administration that authority, under the President, resides in the Secretary of the Treasury. So it is not against the Secretary of the Treasury nor against the Surgeon-General of the Public Health and Marine-Hospital Service that Senator Owen directs his shafts, but rather against the laws that permit a system that belittles that which ought to be dignified and weakens that which ought to be strengthened.

The action of the Department of the Treasury during, we believe, the secretaryship of Hon. Leslie M. Shaw, with respect to the bubonic plague at San Francisco, is urged by Senator Owen as an additional reason why that department should not remain in executive control of our health interests. The charge in this instance involves the suppression of the report of the board of experts from Feb. 26, 1901, to April 19, 1901. Senator Owen said: "The commercial interests of San Francisco had triumphed over the bureau and compelled the Surgeon-General, the head of the bureau, by order of his superior officer, the Secretary of the Treasury, to agree to suppress the report contrary to the obvious moral and sanitary duty of the United States. From that time bubonic plague has widened the area of its terribly dangerous infection from Los Angeles to Seattle, passing from rat to rat and squirrel to squirrel and from these animals to an occasional human being through the agency of the common flea."

With respect to this charge the Surgeon-General of the Public Health and Marine-Hospital Service, "by permission of the Assistant Secretary of the Treasury," dictated this statement: "There was a time when the commission of three experts was sent out there and verified the existence of the plague and it was known that this full report was on the way when it was evident a great sensation was expected and the full report of the commission was not published immediately, although the essential facts were published. It was evident that a wide sensation beyond what was evident and what was proper could have been made out of the report of this committee and it was so handled that, while the central facts were not delayed, still the sensational report which would inflict injury on the State of California for an indefinite number of years was prevented."

Apparently the Treasury Department was more concerned about the receipts of the custom house at San

---

[1] Department of Medical Economics, p. 1150.

Francisco than about stamping out the plague. Evidently "revenue" and "health" are such incompatible propositions that, in fairness to either, they cannot be administered jointly by the same agency.

Senator Owen has made clear that any attempt at progressive legislation must be in the direction of a department and not of a bureau, since the latter is the very thing from which we are endeavoring to escape. On this point, Senator Owen insists, as President Taft pointed out, that "it is generally agreed that these bureaus should all be brought together as one working body. To bring established bureaus under a new 'bureau of public health' would be to lower the dignity of the present bureaus by making them the subordinate bureaus of a new bureau which would be offensive to every bureau so subordinated. To bring these bureaus under a department would not lower the dignity of a bureau thus coordinated with other bureaus under the department and would, I believe, generally meet the approval of the government officers employed in the bureaus so coordinated, giving them a new dignity by being a distinct branch of a department of public health, through which they could enlarge their efficiency and find better expression and publicity of work done for the public health." These considerations prompted Senator Owen to introduce this bill providing for a department and not for a bureau.

It is impossible to review every phase of Senator Owen's speech, the full text of which will be sent by him to any one on application. This movement and especially this enthusiastic propaganda on the part of a United States Senator is gratifying and encouraging to all those who have long sought to interest our national legislators in public health matters. If as a result a Department of Health is created, the visions of years will be realized. Even if this end, so much to be desired, cannot be secured, the campaign ought at least to insure a strong bureau of public health located in a department in which its work shall be untrammeled and not subordinated to other interests. Such a result will be a marked advance in the campaign for the protection of public health, and, even if it is not all that can be desired, will be well worth the effort.

THE FOURTH-OF-JULY SACRIFICE—MUST WE HAVE IT THIS YEAR?

Seven years ago THE JOURNAL, realizing the enormous sacrifice of human life in connection with our annual celebration of the Fourth of July, and believing that the public should be made accquainted with the actual figures, undertook to gather and publish accurate statistics regarding the matter. Every possible care has been taken each year in collecting these statistics, large numbers of individual cases being followed up, and sufficient time being allowed to elapse before final publication so as to include termination of the cases of lockjaw following Fourth-of-July wounds. For the first year or two the figures presented were apparently not appreciated but gradually they have been, and during the last two or three years they have been made the basis of a propaganda for a more sensible method of celebrating our national holiday. While the results of the propaganda have not been all that could be wished, it is most encouraging when cities like Baltimore, Cleveland and Washington have taken such a vigorous stand that last year they eliminated the fatalities and practically all of the casualties.

The outlook this year is promising. Never before has the subject been so widely and earnestly discussed in all classes of publications. The statistics have been utilized by the monthly magazines, and by various kinds of periodicals, including the newspapers. One magazine[1] this month devotes four pages to graphic illustrations of the horrors of the day as they have been observed in the past, and uses the statistics compiled by THE JOURNAL—although without credit—to show the gruesome results. Another magazine[2] calls attention to the "coming sacrifice" and says that "for scores of healthy happy boys and girls the days of life are nearly ended." It pictures startlingly the results of a vote by Congress, if that were possible, to sacrifice one unknown boy each year as a national Fourth-of-July offering—the extra editions of newspapers announcing this extraordinary action, the editorial denunciation of the law-makers, the public agitation and excitement, the petitions to Congress and the President, and the civil war that would surely follow an attempt to execute the decree. Such an attempted sacrifice, of course, is an impossible one, as the magazine says, but, if it could be seriously suggested for a moment, the pictured results would be true in every detail. All this would occur over the contemplated sacrifice of one unknown boy; and yet we supinely allow, year after year, the slaughter of hundreds, and the mutilation of thousands, causing desolation and anguish in many homes.

The public is becoming aroused on the subject. In every part of the country individuals, civic societies, and other organizations are taking up and vigorously agitating the matter, and one organization has taken steps for the formation of a national committee for the promotion of a "safe and sane Fourth." In cities, in which quickest and best results can be obtained, the authorities are taking action, and to those already having effective legislation many will be added this year. The medical profession, which comes in immediate contact with the results of the present custom of celebrating the holiday and realizes their frightful extent, should take the lead in agitating such measures as will speedily put an end to this needless sacrifice of life and limb.

physiologic chemistry and comparative pathology, and the reorganization on new lines of the Henry Phipps Institute for the study, prevention and treatment of tuberculosis.

The Henry Phipps Institute is to be organized into three distinct lines of work—social, laboratory and clinical—and all these departments will be used to a more or less considerable extent in teaching medical students, and thus in spreading more widely knowledge concerning tuberculosis and the methods of attacking it. Generous financial provision has been made for the departments of research medicine and physiologic chemistry and for the Phipps Institute, the endowment for these three consisting of gifts aggregating $800,000.

The department of pathology will be in the hands of Dr. Howard T. Ricketts of the University of Chicago; the head of the department of pharmacology is not yet announced; the department of research medicine will be in the hands of Dr. Richard M. Pearce, now professor of pathology of the University and Bellevue Hospital Medical College, while Dr. Alonzo Englebert Taylor of the University of California will head the department of physiologic chemistry, and Dr. Allen J. Smith the new department of comparative pathology.

These extensive changes in the oldest medical school in the United States are sure to have a profound influence. They constitute another illustration of the present rapid development of medical education in this country.

SENATOR OWEN ADVOCATES A DEPARTMENT OF HEALTH

The declaration of President Taft at the University of Pennsylvania last year that "certainly the economy of the union of all health agencies of the National Government in one bureau or department is wise" bids fair to find expression in law. This is shown by the bill introduced by Senator Owen, providing for a Department of Public Health. In advocating the bill,[1] Senator Owen pleaded the law of precedent in accordance with which other departments have been created by assembling and coordinating pre-existing bureaus, and urged Congress to redeem the pledges on this subject made in the platforms of both the great political parties. He also pointed out the necessity of having a department with ample power, as the only means of conferring on the health agencies of the country such prestige and influence as would afford adequate protection to the people.

Senator Owen made some statements which tend to impeach the Department of the Treasury as a competent administrator of the health interests of the country. He stated that when he applied to the Surgeon-General of the Public Health and Marine-Hospital Service for certain information, he, a senator of the United States, could not get the information for two weeks or until the Secretary of the Treasury had returned to Washington. When the Surgeon-General finally made a statement to Senator Owen it was by express permission of the Assistant Secretary of the Treasury. This is an illustration of the humiliating status of our national health service under the existing system. It is true that until recently the Public Health and Marine-Hospital Service has been more distinctly autonomous than would seem to be indicated by the two foregoing incidents, but it was only by tolerance and not because the Secretary of the Treasury did not have the power at any time to subordinate that service by executive order. Nor can we reproach the Secretary of the Treasury. Central responsibility must carry with it central authority, and in national health administration that authority, under the President, resides in the Secretary of the Treasury. So it is not against the Secretary of the Treasury nor against the Surgeon-General of the Public Health and Marine-Hospital Service that Senator Owen directs his shafts, but rather against the laws that permit a system that belittles that which ought to be dignified and weakens that which ought to be strengthened.

The action of the Department of the Treasury during, we believe, the secretaryship of Hon. Leslie M. Shaw, with respect to the bubonic plague at San Francisco, is urged by Senator Owen as an additional reason why that department should not remain in executive control of our health interests. The charge in this instance involves the suppression of the report of the board of experts from Feb. 26, 1901, to April 19, 1901. Senator Owen said: "The commercial interests of San Francisco had triumphed over the bureau and compelled the Surgeon-General, the head of the bureau, by order of his superior officer, the Secretary of the Treasury, to agree to suppress the report contrary to the obvious moral and sanitary duty of the United States. From that time bubonic plague has widened the area of its terribly dangerous infection from Los Angeles to Seattle, passing from rat to rat and squirrel to squirrel and from these animals to an occasional human being through the agency of the common flea."

With respect to this charge the Surgeon-General of the Public Health and Marine-Hospital Service, "by permission of the Assistant Secretary of the Treasury," dictated this statement: "There was a time when the commission of three experts was sent out there and verified the existence of the plague and it was known that this full report was on the way when it was evident a great sensation was expected and the full report of the commission was not published immediately, although the essential facts were published. It was evident that a wide sensation beyond what was evident and what was proper could have been made out of the report of this committee and it was so handled that, while the central facts were not delayed, still the sensational report which would inflict injury on the State of California for an indefinite number of years was prevented."

Apparently the Treasury Department was more concerned about the receipts of the custom house at San

Medical News

DISTRICT OF COLUMBIA

Personal.—Dr. John E. Walsh, sanitary inspector and bacteriologist of the health department of Washington, has resigned.——Dr. Tom A. Williams, Washington, has been elected foreign corresponding member of the Paris Neurologic Society.

Society Election.—The Medical Society of the District of Columbia, at its annual meeting, elected the following officers: Dr. Louis Mackall, president; Drs. D. Olin Leech and Philip S. Roy, vice-presidents; Dr. Dwight G. Smith, corresponding secretary; Dr. Henry C. Macatee, recording secretary; Dr Charles W. Franzoni, treasurer; Dr. Edwin L. Morgan, librarian, and Drs. D. Olin Leech, Henry B. Deale, Francis R. Hagner, John F. Moran and Raymond T. Holden, censors.

GEORGIA

Sanatorium Site Selected.—The City and County Subcommittee on the Tuberculosis Sanatorium site for Atlanta has decided on a piece of property, thirty-seven acres in extent, half a mile from the new city limits, high and well-drained, for which $7,000 is asked. The committee has already $20,000 in hand and can secure $10,000 more when it is desired.

State Medical Society Meeting.—The Medical Association of Georgia will hold its annual meeting in Athens, April 20-22. At the meeting of the council of the association, held in Cordele, March 10, Dr. Claude A. Smith, Atlanta, secretary-treasurer of the association, resigned on account of pressure of business, and Dr. Jarrett W. Palmer, Ailey, was elected to fill the unexpired term.

Personal.—At a called meeting of the Medical Examining Board of Georgia, held in Atlanta, March 9, Dr. Isham H. Goss, Athens, resigned as president of the board, and Dr. Francis M. Ridley, Lagrange, was elected for the unexpired term. Dr. Goss was elected to fill the unexpired term of Dr. Edwin R. Anthony, Griffin.——Drs. Bernard Wolff and Miller B. Hutchins have opened a sanitarium for the treatment of cancer in Atlanta.

ILLINOIS

Hospital News.—Dr. Paul E. N. Greeley has commenced the erection of a private hospital in Waterman.——An addition costing $25,000 will be made to St. Vincent's Hospital, Taylorville.

Building for Tuberculous Nurses.—The Illinois State Association of Graduate Nurses is endeavoring to raise $10,000 for the erection of a building to be used for the care of nurses attacked by tuberculosis.

County Sanatorium.—The board of supervisors of LaSalle county has recommended the remodeling of the present Isolation Hospital so that the building may be used as a county sanatorium for tuberculosis. A large porch is to be constructed around the building and proper provision made for open-air treatment.

County Retains Hospital.—At a meeting on March 23, of the Hospital Commission, consisting of representatives of Cook county and Chicago, it was decided that the county hospital is to be retained in charge of the county board. No more contagious diseases are to be treated in the institution and the city will build a hospital for contagious diseases.

Personal.—Dr. Glen W. Putnam, Grand Crossing, has succeeded Dr. I. W. Howard as surgeon of the Burlington Relief Association at Aurora.——Dr. Samuel M. Wylie, Paxton, has returned from Palm Beach, Fla., greatly improved in health.——Dr. Eugen Cohn, assistant superintendent of the Anna State Hospital, has been appointed assistant superintendent of the Peoria State Hospital.

Gives Site to Hospital.—Mrs. Helen Morris, wife of Edward Morris, Chicago, has deeded the site of the Chicago Home for Convalescent Women and Children, valued at $10,000, to that institution. The gift makes possible the addition of a children's ward. The building at present on the site will be remodeled and a new four-story structure will be erected, doubling the capacity of the home.

INDIANA

Society Meeting.—The third annual meeting of the Fifth District Medical Society was held in Terre Haute, March 3. Dr. Orion E. Maddox, Rockville, was elected president; Dr. Daniel B. Miller, Terre Haute, vice-president; Dr. J. Randolph Gillus, Terre Haute, secretary, and Dr. Myron A. Boor, Terre Haute, treasurer.

Irregular Practitioners Found Guilty.—Colonel E. Wittey, Terre Haute, an advertising specialist, is said to have been fined $25 recently for practicing medicine without a license.——C. O. Buis, a so-called "suggestive therapeutist," of Princeton, is said to have been found guilty of practicing medicine without a license, March 10, and fined $25 and costs.

Personal.—Dr. Thomas H. McCorkle, Black Hawk, formerly of Terre Haute, is reported to be critically ill in St. Anthony's Hospital in that city.——Dr. Henry A. Denison, Indianapolis, is reported to have been committed to the Central Hospital for the Insane.——Dr. James D. Hillis, health officer of Lafayette, is a patient in St. Elizabeth's Hospital on account of an injury to the eye, caused by a long hatpin.

Ask for Larger Hospital.—The Indianapolis Medical Society is to bring pressure to bear on the city council to secure better accommodation at the City Hospital. The resolution adopted called on the authorities to take up the question of hospital care without delay, and to give to the community and city a hospital commensurate with its needs, and with the modern conceptions of the proper care of the dependent sick.

New Hospital Opens.—The Indiana Steel Company formally opened its hospital at Gary, March 23. The hospital is admirably located, well built and thoroughly equipped, has accommodation for about 125 patients, and has cost the company about $2,000,000. A special train from Chicago carried a number of Chicago physicians and other invited guests to be present at the dedication. The hospital will take care of the injured from all the industrial plants of Gary. Dr. Ira Miltimore is in charge of the institution.

LOUISIANA

Leprosy Found.—It is reported from Estherwood that a case of leprosy has been found at Mermentau Cove in Acadia parish. There are said to be nine other cases in the cove.

Extra Protection Secured.—The efforts of the health officers of the state and New Orleans to secure for the city during the summer months extra protection has been successful. The supplemental local inspection by the United States Public Health and Marine-Hospital Service will be reestablished.

Milk Commission Planned.—A milk commission to work in conjunction with the New Orleans and Louisiana boards of health, in the interest of a pure milk supply is proposed by the state pure food commissioner, Dr. Hamilton P. Jones. The duties of the proposed commission will be to ascertain what dairies have attained the specific standard, to give such dairies certificates.

Elections.—At the annual meeting of Webster Parish Medical Society, held in Minden, March 15, the following officers were elected: President, Dr. John E. Rooks, Doyline; vice-president, Dr. Risdon W. Smith, Dubberly; secretary, Dr. Shelly F. Martin, Minden; and treasurer, Dr. Rutledge C. Tompkins, Minden.——Dr. Edward L. McGehee, New Orleans, organizer of the Louisiana Antituberculosis League, organized a branch society at Lafayette, March 11. Dr. Lambert O. Clark was elected president of the league and Dr. George A. Martin, vice-president.

Personal.—Dr. Isidore Cohn has been elected by the board of managers of the Touro Infirmary, New Orleans, outdoor physician to the poor, vice Dr. Jules Lazard, deceased.——Dr. Domingo Bornio, New Orleans, has been elected grand dictator of the Louisiana Grand Lodge of the Knights of Honor.——At a meeting of the Italian Mutual Benefit Societies and other organizations at Hotel Monte Leone, March 18, Dr. Joseph A. Danna, chief surgeon of the Charity Hospital, the guest of honor, was presented an oil painting of himself, and also with a handsome engrossed scroll containing expressions of regard and esteem.

Popular Medical Lectures.—An extensive course of lectures under the auspices of Tulane University, Medical Department, New Orleans, began March 16, and will continue until April 22. The list of subjects is as follows: March 16, Dr. Charles W. Duval on "Cancer;" March 23, Dr. G. Farrar Patten on "Recollections of Student Life in Germany;" March 30, Dr. George Dock on "Typhoid Fever;" April 6, Dr. Charles Chassaignac on "Sexual Continence and Prophylaxis;" April 12. Dr. Paul Michinard on "The Management of Labor;" April 13, Dr. Jacob A. Storck on "Hygiene of the Gastrointestinal Tract;" April 19, Dr. C. Jeff Miller on "The Anatomical Basis Underlying Injuries and Repair of the Pelvic Floor;" April 26, *Irving Hardesty, Ph.D., on "The Anatomy* of the Ear in Relation to Theories of Hearing;" and April 27, Dr. J. T. Hasley on "Physiologic Action of Some Much-Used Drugs, with Demonstrations."

MARYLAND

Protest Against Optometry Bill.—The Medical and Chirurgical Faculty of Maryland has made a protest against the optometry bill at present before the legislature, *on the ground that it will license unskilled* men to treat diseases of the eye.

Personal.—Dr. Thomas C. Bussey, Texas, was stricken with cerebral [illegible] 19.——Dr. Ira Remsen, president of Johns [illegible], has been appointed a *delegate* from that institution to the centennial celebration of Berlin University, to be held next October.——Dr. *Granville* H. Richards, assistant superintendent of the University Hospital, Baltimore, has *settled* for practice at Fort Deposit.

Medical Association Meeting.—At the annual meeting of Howard County Medical Association, held in Ellicott City, March 19, the following officers were elected: President, Dr. Charles C. Tumbleson, Glenelg; vice-president, Dr. John M. B. Rogers, Ellicott City; secretary, Dr. Frank O. Miller, Ellicott City; delegate to the Medical and Chirurgical Faculty of Maryland, Dr. Arthur Williams, Elk Ridge, and censors, Drs. John M. B. Rogers, Bernard J. Byrne, and William B. Gambrill, *all of Ellicott City.*

Report of Sanatorium.—The biennial report of Eudowood Sanatorium shows that 89 per cent. of the cases were cured, arrested, or improved, and that no deaths had occurred. There were 337 patients treated, of whom 159 were discharged. The total expenditures for the biennium were $37,539, and the profits from the farm were $624. During the last two years there has been a deficit of $13,500, and the legislature is asked *to appropriate $15,000, and a per capita allowance for main*tenance on the same basis as is allowed for the state sanatorium.

State Appropriations.—Dr. Hugh H. Young, president, and Dr. Arthur P. Herring, secretary of the Lunacy Commission, point out that by the bond issue of $600,000 *for the state care of* the poor insane, the state will save $285,000 in 1911 and 1912, and also that the bond issue will add only *one cent to the state* tax and will be paid off in fifteen years. The general appropriation bill as agreed by the committees of the two houses of the legislature, leaves out the appropriation of $10,000 asked for by the Medical and Chirurgical Faculty of Maryland, and the appropriation of $4,000 a year asked for by each of the four medical colleges of Baltimore. Johns Hopkins *University* is given $25,000 a year.

Baltimore

Must Report Births.—An ordinance is being prepared by the health department of Baltimore providing a penalty for failure of physicians to report births. It is asserted that the registration of births in Baltimore is more *incomplete than in any* other civilized city in the world.

Money for Baltimore Hebrew Hospital.—Mr. Frank Cahn, New York City, has given $1,000 toward the maintenance of the Children's Summer Camp of the Hebrew Hospital, which was started last year.——By the will of Samuel Frank the Hebrew Hospital *is bequeathed* $500.

Tribute to Dr. Welch.—On the evening of April 2, several hundred distinguished *representatives of medicine, science,* literature and art, industry and statesmanship are to assemble at a dinner at the Belvidere, given in honor of Dr. William Henry Welch. This tribute is in recognition of the commanding *position* in the field of pathology occupied by Dr. Welch, of his work in original research for the diminution of human suffering and saving of human life, and of his election *to the presidency* of the American Medical Association.

MASSACHUSETTS

Fund for Children's Hospital.—The building fund for the Children's *Hospital,* Huntington avenue, Boston, now amounts to $245,050, of which Francis W. Hunnewell, Wellesley, has contributed $150,000. During 1909 1,303 patients were cared for in *the wards* of the institution, 25,895 outpatients were treated, and 1,951 visits were made by the outdoor department. The new buildings will accommodate 150 patients, doubling the present capacity of the institution.

Bequests.—Vincent Memorial Hospital and Emergency Hospital, Worcester, each receives $2,000 from the estate of Mrs. Sarah E. Foster.——By the will of Mary S. Spaulding, Groton, a bequest of *$5,000 each is made* to the New England Hospital for Women and Children, the Massachusetts General Hospital, Perkins Institution for the Blind, and the Boston Home for Incurables.——By the will of the late Freeborn F. Raymond, the Newton Cottage Hospital is bequeathed $5,000 to endow the Mary P. Raymond free bed.

Personal.—The summer home at Hamilton of Dr. Orran G. Cilley, Boston, was entirely destroyed by fire, March 26.——Dr. John A. Leitch, Andover, has been appointed town physician.——The Worcester Home of Consumptives Association, at its annual meeting, March 8, *elected Dr. Carl* Crisand, president, and voted to *endorse the bill* giving cities and towns the right to erect public sanatoria *for* the care of incurable cases of tuberculosis, and provide for the establishment of the sanatoria by a mill tax.——Dr. William J. Collins has resigned as chairman of the board *of health of Northampton.*——Dr. William N. Noyes has been elected city physician of Salem.——Dr. Joseph F. O'Shea has succeeded Dr. Frank E. Stone as city physician of Lynn.——Dr. Charles W. Page, superintendent, and Dr. *Charles* Ricksher, assistant superintendent, of the State Insane Hospital, Danvers, have resigned.——Dr. *Maurice V. Tyrode, faculty instructor in pharmacology in Harvard* Medical *School,* has *resigned to take* effect September 1.

MICHIGAN

County Sanatorium to Be Established.—The Houghton County Board of Supervisors *adopted a resolution* at its last meeting *to submit to* voters at the spring election the proposition to raise $15,000 for the erection and maintenance of a county sanatorium for tuberculosis.

The Health of Manistee.—*Dr. Szymon Szudrawski, health* officer of Manistee, in his annual report, states that during the past year 652 *investigations* were *made,* of which 163 were positive; *312 cases of infectious* diseases were reported, and 269 disinfections were made, at a total *cost to the city* of *only* $224.17.

Lodge Practice.—At *the recent meeting* of the Oakland County Medical Society, held in Pontiac, an amendment to the constitution *of the society* was *passed by* a vote of 32 to 5, which stipulates that no member shall continue to do lodge practice and still continue to be a *member* of the society, unless he obtains for his *compensation fees similar* to those established by usage in the *community* in which he resides.

Sentenced to Prison.—Dr. George A. Fritch, Detroit, said to have been convicted of manslaughter in the case of Maybelle Millman, Ann Arbor, who died as the result of a criminal operation, was sentenced to imprisonment *for an indeterminate* term of seven and a half to fifteen years in the state penitentiary. The judge, *in making the usual recommendation in* indeterminate sentence law, recommended that the sentence of the prisoner be for fifteen years.

Personal.—Dr. Roy C. Perkins has succeeded Dr. Charles F. H. Freiberg as health officer of Bay City, and Dr. Harvey Gilbert has been placed in charge of the smallpox cases in the city.——Dr. Mina L. Fuller, physician of the State Industrial Home for Girls, Adrian, since 1891, has resigned, and Dr. *Emily* S. Stark, Detroit, has been chosen her successor.——Dr. Oscar C. Breitenbach has been appointed Escanaba representative of the State Board of Health on the regulation of the public water supply.——Dr. Flemming Carrow, Detroit, for eighteen years a member of the faculty of the University of Michigan, and a member of the State Board of Registration in Medicine, has decided to give up practice and has purchased a farm in the state of Washington.

MINNESOTA

Abortionist Sentenced to Jail.—Mrs. Elizabeth Schmitz, a midwife of St. Paul, who pleaded guilty March 14, to the charge of criminal abortion, has been sentenced to imprisonment for one year in the county jail.

Public Safety Commission Proposed.—Dr. Henry M. Bracken, secretary of the State Board of Health, has suggested a commission on public safety as one of the future possibilities of the state. His idea is to have a commission composed of three men, which will be in continuous session, and who will do the work now done by the Bureau of Labor, the Health Department, and the Dairy and Food Commission.

Personal.—Dr. John Jackola, Duluth, has returned after a years' stay in Berlin.——Dr. William D. Kelly, St. Paul, has been appointed chief surgeon of the Chicago, Milwaukee and St. Paul Railroad for Minnesota, Iowa and Wisconsin.——Dr. Albert F. Groves, Brainerd, who has been seriously ill with rheumatism, is reported to be improving.——Drs. Arthur S. Adams, Rochester, Charles E. Fawcett, *Stewartville, Frederick* L. Smith, Chatfield, Rolla C. Dugan, Eyota, and George Steven, Byron, have been appointed by the county commissioners of Olmstead county, physicians for the districts in which they are located.

MISSOURI

St. Louis

New Building for Hospital.—The St. Louis Skin and Cancer Hospital, which has been in operation in an old hospital building since its inception in 1906, will in the early summer occupy its new four-story hospital building, with largely increased facilities for the study and treatment of cancer and skin diseases. The hospital is wholly charitable, no private or pay patients being admitted. The funds for the erection of this new structure were furnished by Mr. George D. Barnard of St. Louis, the founder of the hospital, for whom the institution is to be named. It will be complete and modern in every detail, and specially constructed for the study of skin and cancer diseases. The Board of Directors has lately appropriated the sum of $8,000 annually for the department of cancer research, and has secured the services of Prof. Leo Loeb of the University of Pennsylvania, as director of research. The fourth floor of the institution has been reserved for the exclusive use of the research laboratory, and is to be fitted with all the apparatus necessary to prosecute the work along scientific lines. The directors are at present raising an endowment fund of sufficient magnitude to perpetuate the usefulness of the institution; so far they have met with gratifying success and hope in a short time to have sufficient means to put the institution on an adequate financial basis. The report of 1909 has not as yet been compiled, but that of 1908 shows an abundance and variety of clinical material for the prosecution of this special work.

NEW YORK

Medical Examination.—On April 23, the State Civil Service Commission, Albany, will hold an examination for medical superintendent of Letchworth Village, $4,500 with maintenance for superintendent and family. Applications should be filed before April 16.

Vital Statistics for January.—There were 12,866 deaths in the state during January, as compared with 11,481 in January, 1909. Influenza had an increased prevalence and fatality. Measles continued to be extremely epidemic. With an average daily mortality of 415, the death rate was 17.8 per 1,000. The birth rate for the month was 23.2 per thousand population.

Medical Society Elections.—At the annual meeting of Utica Medical Club, March 17, the folowing officers were elected: Dr. John Gormann, president; Dr. Arthur M. Johnston, vice-president; Dr. Frederick R. Ford, secretary-treasurer, and Drs. Morris J. Davies, William J. Schuyler, and William B. Roemer, trustees.——Preliminary steps were taken March 16, for the organization of a new medical society at Canandaigua, to be known as the Canandaigua Medical Association. Dr. Frank A. Brockmyre was temporary chairman and Dr. George W. Gregg, temporary secretary of the meeting.

New York City

Gift to Medical School.—Mrs. Helen Hartley Jenkins has given $100,000 for the endowment of the Marcellus Hartley Chair of Medicine in the New York University and Bellevue Hospital Medical College.

New Courses in Medicine at Columbia University.—During the summer of 1910 a new course in clinical pathology, bacteriology, physiologic chemistry, nutrition, and physical and medical diagnosis, will be instituted.

The Harvey Society.—The eighth lecture of the Harvey Society will be delivered by Professor Magnus-Levy of the University of Berlin at the Academy of Medicine, New York, on April 9 (not on April 2 as previously announced), at 8:30 p. m. The subject of the lecture will be "Pathology and Therapy in Diseases of Metabolism."

Cartwright Lectures.—Professor Magnus-Levy of the University of Berlin will deliver the three Cartwright Lectures of the Alumni Association of the College of Physicians and Surgeons of Columbia University at the New York Academy of Medicine, 17 West Forty-third street, on April 11, 12, and 13, at 5 o'clock. The subject of the lectures will be "Some Phases of the Chemistry of Diabetes."

Personal.—Dr. A. O. Shaklee, assistant in physiology and pharmacology in the Rockefeller Institute for Medical Research, has been appointed assistant professor of pharmacology in the Philippine Medical School, Manila.——Dr. Nell G. W. Bartram has been appointed a member of the staff of Kings Park State Hospital.——Dr. and Mrs. Simon Flexner and Dr. J. Morgan Howe have sailed for Bermuda.

Closer Relations Between College and Hospitals.—Closer relations are being established between the College of Physicians and Surgeons and Mount Sinai Hospital and the German Hospital. Drs. Nathan E. Brill, Emanuel Libman, Arpad G. Gerster and Henry W. Berg, of the staff of Mount Sinai Hospital, and Drs. Frederic Kammerer, Norbert Stadtmuller, and Otto Hensel, of the staff of the German Hospital, have received appointments in Columbia University.

Fellowship in Pathology.—Mount Sinai Hospital announces the establishment of a second fellowship in pathology to be known as the Eugene Meyer, Jr., Fellowship. The income of the fellowship, like that of the first, established in 1908, is $500 per annum. It is open to all graduates in medicine, and the term of appointment is for one year with renewal at the option of the committee, composed of Drs. Abraham Jacobi, Arpad G. Gerster, Frederick S. Mandlebaum, and Emanuel Libman. The object of the fellowship is the furtherance of scientific work of the hospital and to aid students to obtain laboratory training. The work may be done either in Mount Sinai Hospital or elsewhere, under the direction of the pathologist of the hospital.

Buffalo

Personal.—Dr. Charles F. Howard has been appointed chief of the medical staff of Providence Retreat, vice Dr. William C. Krauss, deceased.——Dr. John H. Pryor has been elected president of the board of trustees of the J. N. Adam Memorial Hospital.

Alumni Election.—At the annual meeting of the Buffalo General Hospital Alumni Association, held in Buffalo, Dr. Ernest L. Shurly, Detroit, Mich., was toastmaster. Dr. James W. Putnam was elected president; Dr. Frederick C. Busch, Buffalo, vice-president, and Dr. Thew Wright, secretary-treasurer.

Free Dispensary Established.—The Board of Health has decided to establish and maintain a free dispensary at the city hall, and has appointed Dr. Walter H. Vosburg, and Messrs. Frank E. Murphy and John T. Kornprobst as a commission to provide the necessary quarters, hire trained nurses, and furnish the equipment.

Gift for Nurses' Home and Contagious Pavilion.—Mrs. William Hamlin has bought the property adjoining the Children's Hospital on the west and has intimated that she will present the site to the management with the distinct stipulation that the money needed is raised for the new home. The new contagious pavilion for the hospital will cost about $30,000, of which $12,000 has already been subscribed.

PENNSYLVANIA

Personal.—Dr. Michael Austin, Josephine, has been appointed chief surgeon for the Lackawanna Coke Company at Wehrum, to take effect April 1.——Dr. Louis Jurist, Philadelphia, who has been seriously ill with pneumonia, is convalescent.——Dr. Florence H. Richards, Philadelphia, has been apponted medical director and teacher of physiologic hygiene in the William Penn High School for Girls.

Site for Tuberculosis Camp Acquired.—The state commissioner of health announced March 24 that he had purchased for $18,305, 311 acres of land near Hamburg, Berks county, for the state, on which the department of health will establish its proposed Eastern State Sanatorium for Tuberculosis. The site is in the foothills of the Blue Mountains, a mile from Hamburg, is very picturesque and is admirably adapted for the use to which it is to be placed.

Care for State's Defective Children.—A successful movement has been inaugurated by the Pyschologic Clinic of the University of Pennsylvania to extend throughout the state its work in the treatment of backward and defective children. The officials of the clinic recently offered their services to any community wishing to make studies in retardation and to gain knowledge of a proper treatment for defectives. Already more than 100 children have been examined by Dr. Leightner Witmer and his associates, who have visited Susquehanna, Media, Williamsport and other towns. It is said that several other school boards have arranged to utilize the services of the clinic.

Philadelphia

New Motor Ambulance.—On March 23, Dr. Joseph S. Neff, Director of Health and Charities, received the third motor ambulance for the use of the Municipal Hospital.

Hospital Pavilion Completed.—The new pavilion of the women's section of the Insane Department of the Philadelphia General Hospital has been completed and will be occupied in a few days. The new building will accommodate about 60 patients.

Railroad to Abolish Public Drinking Cup.—The officers of the Pennsylvania Railroad are endeavoring to perfect plans to abolish the public drinking cup from all waiting rooms in their stations and from all railroad coaches. A plan for individual drinking cups is being developed and will be tried.

Bequests.—The will of the late Henry C. Fox bequeathes $5,000 to the Presbyterian Hospital, $5,000 to the Howard Hospital and Infirmary for Incurables, and $5,000 to the German Hospital.——From the estate of the late Charles E. Etting, valued at $150,000, the sum of $10,000 is set aside to endow two perpetual free beds in the Philadelphia Orthopedic Hospital and Infirmary for Nervous Diseases.——The will of the late Emma M. Shive bequeathes $500 each to the Methodist Hospital and the Philadelphia Home for Incurables.——By the will of the late Anna D. Evans, a bequest of $5,000 is made to the Germantown Hospital and Dispensary for the purpose of endowing a free bed, to be known as the "Thomas Wallis Evans and Anna D. Evans Memorial Bed."

April Housecleaning.—Dr. Joseph S. Neff, of the Department of Health and Charities, advocates calling on all members of the community to engage in a thorough housecleaning the first week in April. The street cleaning contractors will also be called on to aid in the city-wide movement for greater cleanliness as a preventive against the spread of disease. The fact that the death rate has run up this winter to 20 per 1,000, as compared with about 18 last winter and an average rate of 16 for the entire 12 months of 1909, has led to this decision. Among the causes for the increase are believed to be the severity and changeableness of the weather and the labor troubles. As so many men were out of work, it was difficult for their families to obtain proper food. One reason for the general housecleaning the first of April is the prevention of breeding of flies. This is the time to prevent their breeding and absolute cleanliness will go far toward reducing their numbers.

GENERAL NEWS AND COMMENT

Bubonic Plague in Hawaii.—Rear Admiral Cowan P. Rees, commandant of the Naval Station at Honolulu, cabled the naval department, March 19, that two deaths from plague had occurred on the Island of Honokaa and three on the Island of Hilo.

New Medical Association.—A medical association has been organized by the practitioners in the district between Warroad, Minn., and Fort Francis, Ont., and the following officers have been elected: President, Dr. Frank H. Stuart, Baudette, Minn.; vice-president, Dr. Alexander A. McCrimmon, Rainy River, Ont.; and secretary-treasurer, Dr. Dugald McBane, Rainy River.

Naval Medical School Graduation.—The closing exercises of the United States Naval Medical School, Washington, for 1910, were held March 24. Among the features of the program were an address and presentation of degrees by Secretary Meyer, and addresses by Dr. Edward Quintard, New York City, and by Surgeon General Charles F. Stokes. A class of twenty passed the final examination.

Sixth International Congress of Esperantists.—This congress will meet next August at Washington, D. C. Dr. Zamenhof, the founder of Esperanto, and a prominent oculist of Warsaw, Poland, will attend. The American members of the World Esperanto Medical Society will doubtless be present in force, as an effort will be made to organize an American branch of the society. Further particulars may be obtained from Dr. Kenneth W. Millican, 231 Metropolitan Building, St. Louis.

Panama Sanitation Reports Again Published.—In THE JOURNAL, Dec. 11, 1909, we commented on the fact that the monthly publication and distribution of the Reports of the Department of Sanitation of the Isthmian Canal Commission were eagerly looked for and carefully read by sanitarians all over the country and that their discontinuance in March, 1909, was unfortunate. We have now to announce that the reports are again being issued and that the back numbers from April to December, 1909, have been published and are available for reference, and may be obtained from the government printer. As we stated before, these reports are of importance not only in regard to canal sanitation but in regard to the management of diseases in the tropics generally.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, March 19, 1910.

Death from Fright: Curious Charge in a Case of Murder

A curious case of murder has just been tried in which the theory put forward by the prosecution was that the victim died from fright when she discovered that her son was attempting to poison her. An old woman, aged 75, was living alone in Coventry. She had a son who was a great trouble to her and to whom she lent money from time to time. Shortly before Christmas, he went about saying that his mother was very ill and would not live over Christmas, though she was in her usual health and was going about her duties. About this time he purchased some cyanid of potassium, saying that he wanted it for hardening tools. He alleged that he used it on a chisel, but the evidence showed that the chisel had not been so treated. He left the cyanid at his mother's house where there could have been no lawful use for it. He told people from whom he had borrowed money that he would have plenty after her death. On Christmas eve, the woman was found very unwell and drowsy and the prisoner admitted that he had given her laudanum "to do her good." He promised to call a physician and ostensibly went to do so but none came. On January 9 the woman was found lying dead on a sofa. In front of her was a glass which had contained cyanid of potassium. When shown the glass the prisoner remarked, "I know what is in it; it is cyanid of potassium." Asked how it came there, he replied, "How should I know?" He was arrested on the charge of poisoning and then the curious fact arose: the necropsy revealed no cause for death. The organs were healthy and no trace of the cyanid could be found in the body. The amount of cyanid in the glass was so small that in the opinion of the analyst it was not sufficient to cause death. The latter said in his evidence that the absence of all signs was not inconsistent with cyanid poisoning. Cyanid of potassium in the stomach would be converted into hydrocyanic acid, which is very volatile. He was of opinion, however, that death was most probably due to fright or some other external cause. It was suggested that the old woman died from fright when the glass containing the cyanid was presented to her by her son. In this case, he would be as guilty of murder as if she died from taking it. By order of the judge, a solution similar to that found in the glass was prepared and he and the jury smelt and tasted it. The defense was that the whole case rested on suspicion and that the woman died from syncope. The jury found the prisoner guilty of attempted murder. The judge passed the heaviest sentence possible for this crime, penal servitude for life.

Expedition to Study the Effects of High Altitudes

An international expedition for the investigation of the effect of high altitudes on medical and biologic processes has left England for the Peak of Teneriffe. The members are Professor Pannwitz of Charlottenburg, the president of the "International Commission for the Study of Biological and Medical Effects of High Altitudes and Sunshine;" Dr. Bancroft and Dr. Douglas, representing England; Professor Zuntz and Dr. Neuberg, representing Germany; Dr. Mascat and Dr. Plasse. representing Frence; and Professor Durig and Dr. H. von Schrötter, representing Austria. The primary object of the expedition is to continue the observations started by Professor Zuntz and his collaborators on Monte Rosa. At the same time the members will endeavor to extend the knowledge recently acquired of heliotherapy.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, March 10, 1910.

Personal

Like Professor Olshausen, Professor Senator will resign his position at the end of the summer semester. Senator was 75 a short time ago.

New German Mortality Tables

The official German mortality tables based on statistics of the decade from 1891 to 1900 have just been published. The new tables are intended to replace the German mortality tables published in 1887, which were computed on the mortality for the years 1871 to 1881. The new tables give a view of the changes in the death rate in the last thirty years. The average length of life of the male sex was calculated for 1870 as 35.8; for 1890, 40.56. For the female sex the corresponding figures are: 38.45 and 43.97. The expectation of life for the male sex has risen from 38.1 to 48.85, for the female sex from 42.5 to 54.9. This shows a quite important improvement in the life expectancy of the German people.

Professional Courtesy in Regard to Fees

It is an ancient custom in Germany as in many other civilized countries that physicians receive no fee for their treatment of their colleagues and their families. This tradition, founded on an ideal of professional conduct, has led in the course of time to abuses which are much complained of, both by the colleagues treated and by those called on to treat them. In a signed editorial in the *Deutsche medizinische Wochenschrift* last October, Professor Schwalbe discussed these abuses thoroughly. (A summary of his article was published in The Journal, Nov. 20, page 1785.) He came to the conclusion that the conditions of practice have changed so much that a mutual remission of fees to the medical profession is no longer to be regarded as desirable from a professional standpoint. The treatment of the families of physicians forms at the present time a great part of the work of specialists, who formerly were almost unknown, and those among them who are of moderate means cannot afford to receive for their practice either nothing at all or more or less useless presents like bronzes, vases, pictures, etc. On the other hand, the distinguished physicians whose income might well permit such free treatment are so greatly in demand by German and foreign physicians and their families that their other practice suffers. On the other hand, a considerable number of physicians who require the aid of their colleagues for themselves and their families object to the present custom, for one reason because they are not willing to remain under obligations to physicians to whom they are more or less strangers, and as the consultants are averse to receiving pay on account of professional custom, they hesitate to demand their services and often in this way diseases are neglected. Professor Schwalbe proposed that each physician shall be allowed to decide whether he will demand or pay a fee for the services and that a consultant shall no longer be required on the ground of professional courtesy to refuse to receive a fee offered by a colleague. This position has been endorsed by a number of physicians in letters that have been published in the *Deutsche medizinische Wochenschrift*. What is still more important, the business committee of the Berlin medical professional union (*Standesverein*) which includes the greater part of the Berlin medical profession, a few days ago, after a thorough debate, passed the following resolution: "The acceptance of a fee for the treatment of physicians and physicians' families is not to be considered unethical conduct." Thus the present usage will be gradually abandoned to the benefit of many patients and physicians. In practice the ideal which Professor Schwalbe gave at the end of his article may be established: Physicians who are in friendly relations or closely associated in their work will not mutually recompense each other for treatment by money payment, but the specialist will be justified in requiring a fee from distant, unknown, or foreign physicians and their families. On the other hand, every physician will be permitted to pay the adviser for himself and family in a moderate way, and the consultant need not feel himself obliged on account of professional courtesy to refuse the fee. If the latter regards it unprofessional to use such a fee for himself, he may apply it to some humanitarian purpose. In the estimation of the fee it is to be expected of specialists that they will not require the fancy prices occasionally customary with many of them but at most will settle for a moderate fee.

Infant Mortality in Bavaria

The infant mortality in the kingdom of Bavaria has fallen markedly and somewhat steadily in the last six years; in the years from 1903 to 1908 the deaths of children in the first year corresponding to a percentage of those born living, were respectively 25.0, 23.9, 24.1, 22.7, 22.0 and 21.7. In 1900 the infant mortality was 27.8 and in 1878 29.6 per cent. In 1908 two-thirds died from gastrointestinal catarrh and diarrhea or congenital lack of vitality, 36.8 per cent. from the first cause, and 26.8 per cent. from the second. The infant mortality is extraordinarily high only in certain districts where the custom of artificial feeding of new-born children prevails. The coincidence of a high infant mortality with a high birth rate, noted in Bavaria as elsewhere, is associated with the marked extension of artificial feeding for the reason that the mother who nurses her child does not again become pregnant so soon, and that when the deliveries follow each other so rapidly, the new pregnancy gives the mother no time to recover from the exhaustion of the last delivery. The prince regent of Bavaria has contributed $2,500 (7,000 marks) and the government $12,000 for the advancement of infant hygiene.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, March 12, 1910.

Increase of Smoking and Its Effects on Youths

Two reports giving an interesting insight into the effects of tobacco on the population have been recently published.

The financial report of the budget committee of parliament shows that a constant and rapid diminution of the use of cigars is balanced by an equally constant and rapid increase in the consumption of cigarettes. Pipe-smoking and snuffing are nearly 80 per cent. less than five years ago, while tobacco-chewing is practically unknown here. There were 1,212,060,000 cigars sold in this country in 1908, while 4,348,010,000 cigarettes were consumed at the same time. The population being about 28,000,000, of whom only 9,000,000 can be considered as smokers, this works out a high figure per head.

The other report was made by a medical officer engaged for ten years in recruiting work, who for his private curiosity undertook to observe the effects of smoking on the youths whom he had to examine for the army. His list comprises 4,800 youths, aged from 19 to 24. He finds that in rural districts smoking is much less common, at this age at least. Even then pipes are preferred; smoking is done mostly in the open air. In the town population the cigarette is mostly indulged in, oftener indoors than out in the open; the average age at the beginning of smoking, 17, is about equal in the two groups. Youths in schools (colleges, gymnasiums, universities) are nearly always smokers; at least they pretend to be. Only 5 per cent. of the masculine population of this age are non-smokers. Generally speaking, he could not find any marked effects due to moderate smoking among those whom he examined. Only excessive smoking, especially seen in students before examinations during hard study, brought on neurasthenic symptoms: palpitation, indigestion, sleeplessness, tinnitus aurium. He hardly ever saw such conditions in youths engaged in rural occupations, while apprentices and shop assistants showed similar conditions as those seen in students.

Postgraduate Lectures During Vacations

For a few years postgraduate courses have been organized here with much success. Although they were at first only a private experiment their use has been recognized so universally that they have now become a regular part of the teaching at our general hospital. In order to enable all doctors who desire it to partake of the advantages of the classes, it has been arranged by the Vienna medical council that classes of six to twelve hours, lasting one or two weeks, are given by certain professors alternating every month. The fee is very moderate, $1 or $2 per class, which goes to medical charitable purposes. The subjects of the postgraduate classes of this kind are chosen with a view to inform the doctor who is out of touch with the hospitals about the achievements of modern medicine during the last fifteen years or less. Another group of lectures, called the *Ferialcurse* or vacation course, is delivered during the Easter, Christmas and summer months, lasts at least four weeks and comprises one subject, which is taught as intensively as possible. The fees are much higher, $10 to $20; the classes are held mostly by privat-docents or assistants, and the number of the students is limited. They are open to any qualified man, while the classes conducted by the medical council are open only to Austrian doctors. The number of physicians who made use of the opportunities offered them by the medical council was over 400 last year, and the usefulness is best demonstrated by the number of those who have booked for similar courses for this year.

The Temperance Movement in Austria

The temperance movement is growing in this country steadily, though not too rapidly. The energetic managing board of the "Austrian Antialcohol League" has succeeded in turning public attention to its aims by inducing several well-known men, among them the celebrated Professor Forel from Switzerland, to deliver popular lectures on the subject of the evil influence of alcohol on the development of both the body and the mind.

Already it has been demonstrated that temperance exerts a powerful influence on the capability of the laborer, and in many factories and trades only persons are employed who belong to the abstainers or at least to temperance clubs. There is a medical club of total abstainers. Students of all faculties have formed the students' antialcohol club (a fact much more significant than anything else, for the old unwritten laws and customs of the German students made drinking one of the chief recreations of the university men). In several hospitals a non-alcoholic treatment of diseases has been strictly adhered to, and there is an antialcohol press, whose circulation has exceeded that of many of the political papers.

Among the working classes the knowledge of alcohol, of its questionable value as a food, and its unquestionable effects as disease-producer is widely disseminated by lectures, so that in many circles a true alcoholic boycott is permanently declared and observed by the men.

Pharmacology

[CONTRIBUTION FROM THE CHEMICAL LABORATORY OF THE AMERICAN MEDICAL ASSOCIATION.]

THE ESTIMATION OF MERCURY IN ORGANIC COMPOUNDS

W. A. Puckner and W. S. Hilpert

[EDITOR'S NOTE: The preparation here referred to, in an indefinite way, was finally accepted by the Council and is now included in New and Nonofficial Remedies, but with a corrected statement as to its actual composition. The matter is published to call attention to one phase of the work of the Council on Pharmacy and Chemistry. In this instance an honorable firm had for a long time been putting out a preparation which the physician was told contained a certain amount of mercury. It matters not whether the manufacturers were innocent or not, the fact was that it did not contain the amount stated, and the physician would therefore be misled on a very important matter. This report also shows another thing, and that is that honest manufacturers are realizing that it is to their interest to comply with all legitimate demands regarding statements, whether they relate to the actual composition of a product or to its therapeutic value.]

Under a proprietary name there has been on the market for some time a preparation containing a protein compound of mercury, combined with other material. The preparation was submitted to the Council on Pharmacy and Chemistry and the manufacturers gave a chemical formula for the protein compound of mercury which indicated that the mixture should contain 6.57 per cent. of mercury.

At the request of the Council, the preparation was examined in the Association laboratory. The identity of the contents of the mixture was verified by qualitative tests, but a quantitative examination showed that the preparation instead of containing 6.57 per cent. of mercury really contained only 4.27 per cent. The method of examination was that of Kjeldahl. The material was decomposed by sulphuric and nitric acids and the mercury determined as sulphid.[1]

The attention of the manufacturers was called to the result of the examination and they were also given the method used. In reply they questioned the findings and held that the method used was faulty, and proposed a method[1] which differs from the one used in the Association laboratory only in that potassium sulphate was added to the sulphuric acid in place of nitric acid. This method was then employed with the result that in two analyses the mercury compound yielded mercuric sulphid equivalent to 4.40 per cent. of mercury. This showed such a slight increase in the mercury content indicated by the first examination as to be negligible.

As a further check on the method determinations[1] were made according to the method of Schumm in which the organic matter is decomposed by the action of concentrated hydrochloric acid and potassium chlorate and the mercury estimated as sulphid, with the result that the compound yielded mercuric sulphid equivalent to 4.23 per cent. of mercury. Confirmation of the laboratory's findings by their own method having been reported to the manufacturers, they were accepted by them as correct.

The discrepancy between the claims made for a product and the facts established by analysis which were brought out by the examination detailed above furnishes a good illustration of the lack of control exercised in the manufacture of medicinal products and the loose manner in which chemical formulas are applied to substances which are of indefinite, variable composition or which are highly impure. This can be explained in this instance by a lack of cooperation between the scientific staff of the manufacturers and those in charge of the commercial department.

There is no reason for the assumption that the manufacturers knowingly misrepresented the composition of the preparation. On the contrary, they have courted investigation of their products. Thus, when they submitted to the Council the preparation referred to, they voluntarily presented specimens of the constituents so as to facilitate investigation.

---

[1] The details of analysis will be published in the annual report of the laboratory.

The Composition of Manola

Inquiries have been received relative to the composition of Manola, a preparation manufactured by the "Manola Company," said to be a subsidiary concern of the Luyties Homeopathic Pharmacy Company, St. Louis.

Examination of Manola in the Association laboratory indicates that its composition is consistent with its origin, for its medicinal ingredients are present in truly homeopathic quantities. The laboratory report follows:

An examination of an original bottle of Manola gave the following results:

Specific gravity at 25 C........	1.0329
Alcohol	18.00 per cent. by vol.
Non-volatile matter (residue on evaporation)	15.93 gm. in 100 c.c.
Ash	.96 gm. in 100 c.c.
Phosphoric pentoxid (P_2O_5).....	.0668 gm. in 100 c.c.
Total alkaloids	.0047 gm. in 100 c.c.
Calcium	Traces.
Magnesium	Traces.
Iron	Traces.
Sodium	Traces.
Arsenic	Traces.

Manola is a light amber colored liquid having the odor and taste of sherry wine. The above analysis indicates that it is nothing more than wine, fortified with alcohol and a slight amount of medicinal substances added. The non-volatile matter appears to be nearly all sugar, glycerin, or some similar substance and the presence of less than one gram of ash to 100 c.c. excludes the presence of more than a small amount of organic salts. From the amount of phosphorus found there appears to be about one dose of phosphoric acid to a twenty-ounce bottle. Arsenic is present in such small amounts that the ordinary hydrogen sulphid test failed to show its presence and the delicate Gutzeit's test had to be used to detect it.

Some interesting points in regard to the methods of the exploiters of Manola appeared in THE JOURNAL, Aug. 8, 1908, p. 511; Dec. 19, 1908, p. 2172, and have been reprinted in the "Propaganda for Reform."

Correspondence

Views on the Present Organization by the "Father of the Association"

To the Editor:—I have been reading your editorials on the organization of the Association with great interest and satisfaction. I am sure if you will search old speeches made by my father, by Gross, and by others of the old guard, you will find the hope frequently expressed that ultimately the profession of the country would be so organized that every county would have its society and send delegates to a business body of the state society, and that every state society would, in like manner, be represented in the Association—in other words, the organization as it now exists. That this was my father's ideal I know from his frequently repeated expressions to that effect.

Moreover, what may please you was his feeling of gratification when the reorganization was effected that such a representative organization was possible. He also commented on the similarities of function of the council and the business committee, or business council as his committee planned it for adoption, a reform which was adopted and later tabled on a parliamentary technicality, as is stated in your editorial.

N. S. DAVIS, Chicago.

[Dr. Davis merely emphasizes what the records of the Association show and what the older, active members of the Association know—that the general plan of organization, as is now in active operation, was the ideal that for long had been suggested, and especially by Dr. Davis, the "Father of the Association." This is shown in the "argument" accompanying the report of the Organization Committee, presented to the St. Paul meeting in 1901.—ED.]

Arrest of Paroxysms in Whooping Cough

To the Editor:—The following simple method has arrested the paroxysms of whooping-cough in a number of patients in from 3 to 7 days, and has also succeeded in some cases of laryngismus stridulus.

Place a pleximeter on the spinous process of the seventh cervical vertebra and strike the pleximeter a series of moderate blows with a percussion hammer. The number of blows is of little moment but the blows must be as strong as the child can tolerate without flinching. Some of the mothers accompany the blows with a nursery rhyme or song to interest the child. In the absence of a pleximeter and percussion hammer, a strip of linoleum and a tack hammer will suffice. To avoid cutaneous irritation, cotton may be interposed between the linoleum, or pleximeter and the spine. Each seance during the interparoxysmal period should last five minutes thrice daily and the harmless method may be executed by the mother or nurse. I am desirous of collecting reports on this method of treatment; to test the efficiency of the treatment, it would be well to note the number and severity of the paroxysms before and after treatment in each patient.

Albert Abrams, M.D., San Francisco.

246 Powell Street.

The Kentucky Medical Bill

To the Editor:—In The Journal, March 19, an item from your Kentucky correspondent is misleading in that it states that the cause of the failure of the bill was the statement made by Senator Linn in opposition to the bill that "the consolidation of the five medical colleges of Louisville resulted in a number of men losing their positions and this bill was the outcome of the ill-feeling resulting therefrom."

Senator Linn was the political leader of the senate, and was simply following the dictates of the powerful influence brought to bear on him by the so-called University of Louisville, which has fought higher medical education all the time.

This bill was the result of a petition endorsed unanimously last October by the State Medical Association urging the state to establish a medical department of the State University as a necessity for higher and better medical education. It was drawn by President Patterson and his associates of the state university at Lexington. It was a bill that should have passed, and will pass unquestionably at the next legislature.

The bill was not defeated by a vote of eighteen to fourteen, as stated by your correspondent, but it was defeated, after receiving eighteen to fourteen votes in its favor, by a constitutional amendment requiring all bills carrying an appropriation to have twenty votes, of which we lacked two owing to sickness on that day of two of our champions for the bill in the senate.

W. F. Boggess, Louisville, Ky.

[We have received two other protests similar to the above. The item referred to and quoted should not have appeared in The Journal, regardless of whether or not the assertion of Senator Linn was based on fact.—Editor.]

Association News

TRUSTEES' MEETING

Report of Regular Meeting of the Board of Trustees of the Association

The Trustees of the American Medical Association met in Chicago, Feb. 4 and 5, 1910, at the rooms of the Association. Two sessions were held on February 4 and one on February 5. There were present at all sessions:

Dr. M. L. Harris, Chicago (Chairman).
Dr. Philip Marvel, Atlantic City, N. J. (Vice-Chairman).
Dr. Wisner R. Townsend, New York (Secretary).
Dr. Philip Mills Jones, San Francisco.
Dr. W. T. Councilman, Boston.
Dr. W. T. Sarles, Sparta, Wis.
Dr. C. E. Cantrell, Greenville, Texas.
Dr. C. A. Daugherty, South Bend, Ind.

FIRST SESSION, HELD FROM 10:15 A. M. TO 12:30 P. M.

A letter from Dr. W. W. Grant, Denver, was read, in which he stated that he was unable to be present and expressed his regret.

It was moved to dispense with the reading of the minutes of the last meeting, as they had been read and approved.

The Editor and General Manager read his annual report. The recommendations contained therein, for new machinery, were duly considered.

Dr. Sarles moved, Dr. Cantrell seconded, that a new covering machine to cost $3,500 be ordered. Carried.

Dr. Jones moved, Dr. Cantrell seconded, that a new rotary press to cost $18,000 be ordered. Carried.

Dr. Jones moved, Dr. Sarles seconded, that a new book sewing machine to cost $1,350 be ordered. Carried.

A request from Dr. W. B. Cannon was read, asking for an additional appropriation of $500 for the Committee on the Defense of Medical Research.

A request was also presented for an appropriation of $850 for the Council on Pharmacy and Chemistry.

Dr. Charles A. L. Reed presented a request for an additional appropriation for the use of the Committee on Medical Legislation, and made an argument in favor of the same, giving details as to what had been done so far toward the establishment of a bureau of health and what work was necessary in the future. Dr. Cantrell moved, Dr. Marvel seconded, that the request of Dr. Reed for an additional appropriation of $1,250 for the expenses of the Committee on Medical Legislation, from February 7 to June 12, be allowed, and an additional contingent fund of $2,000 be placed at the disposal of the committee, with the proviso that it can only be spent for work done by the committee itself. Carried.

SECOND SESSION, HELD FROM 2:30 P. M. TO 6 P. M.

The minutes of the morning meeting were approved.

Dr. Jones moved, Dr. Cantrell seconded, that the plan of publicity campaign advocated by Dr. F. B. Wynn, chairman of the Committee on Scientific Work, be received and placed on file. Carried.

Dr. Jones moved, Dr. Councilman seconded, that Drs. F. G. Novy, G. H. Simmons and H. W. Wiley be declared elected to the Council on Pharmacy. Carried.

Dr. Jones moved, Dr. Marvel seconded, that the Board of Trustees again call the attention of all officers of the Association and all heads of committees to the necessity of presenting to the Board of Trustees an annual budget, and request that all expenses be kept within the appropriations made. Carried.

Dr. Councilman moved, Dr. Jones seconded, that an additional $500 be appropriated to the Committee on Defense of Medical Research. Carried.

Drs. I. Abt and F. S. Churchill, on behalf of a number of pediatrists, presented a communication requesting the publication, by the Association, of a journal devoted to pediatrics. Dr. Jones moved, Dr. Sarles seconded, that a committee of eleven be appointed by the chairman to secure information for the Trustees in regard to the publication by the American Medical Association, of a journal devoted to pediatrics. Carried. The chairman appointed Drs. I. Abt of Chicago, chairman, and Drs. A. Jacobi, L. E. Holt, Thomas Southworth and G. Pisek of New York, T. M. Rotch of Boston, E. E. Graham and J. P. C. Griffith of Philadelphia, W. J. Butler, J. M. Dodson and F. S. Churchill of Chicago.

Dr. Jones moved, Dr. Sarles seconded, that bill of Dr. McCormack, $842.40, for expenses from July 23 to February 5, be paid. Carried.

Dr. Jones moved, Dr. Councilman seconded, that the $850 requested by the Council on Pharmacy and Chemistry be granted. Carried.

A letter of the lawyers in regard to the status of the American Medical Association Public Health Education Committee of Women was read and ordered spread on the minutes. Dr. Marvel moved, Dr. Daugherty seconded, that the communication received from the chairman of the committee be acknowledged by the chairman of the board. Carried.

Drs. Bracken, Evans and McCormack then appeared before the Board and presented a communication relating to the establishment of a Bureau of Legislation, Organization and Publicity. Dr. Cantrell moved, Dr. Sarles seconded, that the chairman appoint a committee of two from the Trustees, to meet with Drs. Bracken, Evans, Reed, McCormack, Clark and Price (previously appointed by the House of Delegates) to prepare a plan for the formation of this council and to suggest the necessary changes in the Constitution and By-laws to carry the plan into effect, and that this committee report to the Board of Trustees prior to the meeting in St. Louis. Carried.

THIRD SESSION, FEBRUARY 5, HELD FROM 10 A. M. TO 12:45 P. M.

Dr. Sarles moved, Dr. Cantrell seconded, that the chairman be made a member of the committee to devise plans, etc., for the Council on Legislation, Organization and Publicity. The chairman then appointed as members of the committee, from the Trustees, Drs. Harris and Cantrell. Carried.

A report from the Committee on Refraction by Dr. Connor was read and ordered placed on file.

A request was received from Dr. A. D. Bevan and others asking that the Association publish a journal devoted to surgery. Dr. Jones moved, Dr. Councilman seconded, that a committee of eleven be appointed by the chairman to secure information for the Trustees in regard to the publication, by the American Medical Association, of a journal devoted to surgery. Carried. The chaiman appointed Dr. A. D. Bevan of Chicago, chairman, and Drs. J. F. Binnie, Kansas City, Kan.; J. C. Bloodgood, Baltimore; George E. Brewer, New York; George W. Crile, Cleveland, Ohio; A. F. Jonas, Omaha; Rudolph Matas, New Orleans; W. J. Mayo, Rochester, Minn.; J. G. Mumford, Boston; Charles A. Powers, Denver; and Emmett Rixford, San Francisco.

A report from the Committee on Ophthalmia Neonatorum was then read. Dr. Jones moved, Dr. Cantrell seconded, that the report be accepted and the committee thanked for its excellent work. Carried.

Dr. Harris reported progress as a member of the Committee on Postal Relations.

Dr. Jones moved, Dr. Councilman seconded, that Dr. George H. Simmons be reelected Editor and General Manager for the ensuing year. Carried.

There being no further business, the minutes of the meeting were read and approved and the Board of Trustees adjourned *sine die* at 12:45 p. m.

M. L. HARRIS, Chairman.
WISNER R. TOWNSEND, Secretary.

HOTELS AT ST. LOUIS

Rates, Locations and Capacities of Hotels for the St. Louis Session

Members of the American Medical Association desiring to secure hotel accommodations should write to the chairman of the Hotels Committee, Dr. Louis H. Behrens, 609 Metropolitan Building, or direct to the hotels. Many reservations have already been made and prompt attention should be given to this matter in order to secure accommodations in advance.

When writing, please give definite instructions as to the character of rooms desired, whether with or without bath, European or American plan, number of people in the party, and particularly the names of persons who are willing to share rooms.

As the section meeting places are located along Grand avenue, which is a thoroughfare about midway between the east and west ends of the city, the hotels are listed according to their location, and the time consumed in riding to the meeting-places is mentioned.

The first list comprises those hotels located in the downtown, or east, section of the city:

AMERICAN HOTEL, Seventh and Market Sts., 275 rooms, all with bath; can take 350; rate, one person, $1.50 and up; additional, $1 per person; 15 minutes from meeting place.

EDISON HOTEL, 107 N. Eighth St., 12 rooms; can take 24; rate, one person, $1; additional, $1 per person; 15 minutes from meeting place.

HOTEL GARNI, Jefferson and Olive Sts., 50 rooms; can take 50; rate, one person, $0.75 and up; additional, $0.50 per person; 8 minutes from meeting place; near Coliseum.

JEFFERSON HOTEL, Twelfth and Locust Sts., 400 rooms; can take 300; rate, one person, $1.50 and up; with bath, $2.50 and up; additional, $1 per person; *with bath, $1.50 per person*; 8 minutes from meeting place.

LACLEDE HOTEL, Sixth and Chestnut Sts., 170 rooms; can take 150; rate, one person, $1 and $1.50; with bath, $2 to $2.50; additional, $1 per person; 15 minutes from meeting place.

MADISON HOTEL, Broadway and Chestnut St., 112 rooms; can take 100; rate, one person, $1 and up; additional, $0.75 and up; 15 minutes from meeting place.

MARQUETTE HOTEL, Eighteenth and Washington Ave., 400 rooms; can take 250; rate, one person, $1.50 and up; with bath, $2 and up; additional, $1 per person; 8 minutes from meeting place.

MARYLAND HOTEL, Ninth and Pine Sts., 240 rooms; can take 200; rate, one person, $1 to $2; with bath, $2 to $2.50; additional, $1 per person; 10 minutes from meeting place.

MOSER HOTEL, 809 Pine St., 100 rooms; can take 75; rate, one person, $0.75 and $1; additional, $0.75 per person; 10 minutes from meeting place.

PLANTERS HOTEL, Fourth and Pine Sts., 440 rooms; can take 300; rate, one person, $1.50 and up; with bath, $2.50 and up; additional, $1 per person; *with bath, $1.50 per person*; 15 minutes from meeting place.

PORTLAND HOTEL, 1817 Market St., 100 rooms; can take 100; rate, one person, $1; additional, $0.75 per person; 10 minutes from meeting place.

ROZIER HOTEL, Thirteenth and Olive Sts., 120 rooms; can take 180; rate, one person, $0.75 to $1.50; additional, $0.75 per person; *8 minutes from meeting place.*

ST. JAMES HOTEL, Broadway and Walnut, 150 room; can take 200; rate, one person, $1.50; with bath, $2; additional, $1 per person; with bath, $1.50 per person; 15 minutes from meeting place.

ST. NICHOLAS HOTEL, Broadway and Market, 40 rooms; can take 25; rate, one person, $0.75 to $1; additional $0.50 per person; 15 minutes from meeting place.

SOUTHERN HOTEL (General Headquarters), Broadway and Walnut, 400 rooms; can take 200; rate, European plan, one person, $1.50 and up; with bath, $2.50 and up; American plan, one person, $3.50 and up; with bath, $4 and up; additional, European plan, $1.50 and up per person; American plan, $3.50 and up per person; 15 minutes from meeting place.

STRATFORD HOTEL, Seventh and Pine Sts., 100 rooms; can take 150; rate, one person, $1; with bath, $1.50; additional, $0.50 per person; 15 minutes from meeting place.

TERMINAL HOTEL, Union Station, 110 rooms; can take 150; rate one person, $1.25 and up; with bath, $2.50 and up; additional, $1.25 per person; 10 minutes from meeting place.

The following hotels are located in the west end, or residence section, of the city:

BEERS HOTEL, Grand and Olive, can take 40; rate, one person, $1 and up; with bath, $2.50, and up; additional, $1 per person; at meeting place.

BUCKINGHAM HOTEL, Kingshighway and West Pine, can take 100; rate, one person, European plan $1.50; with bath, $2.50; additional, $1 per person; *rate, one person, American plan $3*; with bath, $4; additional, $2.50 per person; 10 minutes from meeting place.

HAMILTON HOTEL, Hamilton and Maple Ave., 150 rooms; can take 50; European plan, rate, one person, $1; with bath, $1.50; additional, $1 per person; American plan, one person, $2; with bath, $2.50; additional, $1.50; 15 minutes from meeting place.

HOTEL BERLIN, Berlin and Taylor Ave., can take 25; American plan, rate, one person, $1.50; with bath, $2.50; additional, $1 per person; *10 minutes from meeting place.*

USONA HOTEL, Kingshighway and McPherson, 100 rooms; can take 50; American plan, rate, one person, $2.50; with bath, $3; additional, $1.50 per person; with bath, $2 per person; 10 minutes from meeting place.

WEST END HOTEL, Vandeventer and W. Belle, can take 25; rate, one person, $1 and up; with bath, $1.50 and up; additional, $1 and up; *5 minutes from meeting place.*

WESTMORELAND HOTEL, Maryland and Newstead Ave., can take 50; all rooms with bath; rate, one person $2; *additional*, $1 per person; 8 minutes *from* meeting place.

WINDERMORE HOTEL, 5601 Delmar Blvd., American plan only; can take 25; rate, one person, $1.50; with bath, $2.50; additional, $1 per person; 15 minutes from meeting place.

PRIVATE HOMES AND BOARDING HOUSES

In addition to the hotels listed there are numerous private homes and boarding-houses on and near Grand avenue, in close proximity to the section meeting-places, where good accommodations can be secured at rates ranging from 75 cents to $1.50 a day, American plan. Those who desire to obtain such accommodations should write to the chairman, Hotels Committee, at the address given above. State clearly what accommodations are desired, for how many people, and at what rate per day.

SECTION HEADQUARTERS

Hotel headquarters for sections have been assigned as follows:

SECTIONS	HOTELS
General Headquarters	Southern Hotel
Surgery	Jefferson Hotel
Dermatology	Jefferson Hotel
Laryngology and Otology	Jefferson Hotel
Practice of Medicine	Planters Hotel
Pathology	*Planters* Hotel
Pharmacology and Therapeutics	Planters Hotel
Ophthalmology	Marquette Hotel
Obstetrics and Diseases of Women	Marquette Hotel
Diseases of Children	Marquette Hotel
Nervous and Mental Diseases	Buckingham Hotel
Preventive Medicine	Buckingham Hotel
Stomatology	West End Hotel

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

UTILIZATION OF GARBAGE IN SUPPLYING POWER FOR WATERWORKS, ETC.

To the Editor:—Can you furnish data concerning the utilization of city refuse, such as garbage and old paper, for supplying power for waterworks and other municipal plants, or tell me where such data can be obtained? STEPHEN C. MASON, JR., Menominee, Mich.

ANSWER.—The economical disposal of garbage and refuse in cities and towns is an engineering as well as a sanitary problem of no small importance, and has been the subject of a great deal of study and experiment. It cannot be said that a practical and economical solution has yet been evolved. In many cities, such refuse has been made a source of revenue to the extent of paying a part of the expense of disposal, but nowhere in this country has it been successfully utilized in the way of fuel for running city plants to the extent named in the inquiry. In Great Britain more success has been attained in this respect, but it is said that such waste contains more combustible material than in this country. In Boston and in New York, and perhaps in some other cities in the United States, incinerators have been established which dispose of a part of the waste. After it is picked over by contractors who pay certain sums for the usable material they can get from it, the residue is burned, sufficient heat being produced to furnish steam for running a belt conveyor and perhaps baling presses. One incinerator under the Williamsburgh bridge in New York also furnishes enough heat to make electric light for lighting the bridge. The proximity of the water in the boilers of steam plants seems to cool the fire so that combustion is not perfect even under forced draft, and if the boilers are placed far enough away from the fire box to overcome this difficulty much of the heat is lost. In many cities and towns where incinerators and plants for the utilization of the waste for power purposes have been established they have later been abandoned and other methods of disposal adopted.

The Public Service

Medical Department of the Army

Changes for the week ended March 26, 1910:

Taylor, Blair D., col., ordered to make an inspection of the Medical Department, and a sanitary inspection of Key West Barracks, Fla., Forts Dade and De Soto, Fla.

Bryan, Ray W., lieut., granted 2 months' leave of absence,

Jordan, Edward H., 1st lieut., M. R. C., orders to Fort Ward, Wash., revoked; relieved from active duty in the Medical Reserve Corps, to take effect on expiration of leave of absence granted him for 1 month and 1 day.

Ruffner, Ernest L., major, on arrival at San Francisco, to proceed to Fort Missoula, Mont., for duty.

Thomason, Harry D., capt., relieved from duty at Fort Missoula, Mont., and will repair to this city and report in *person to the* Chief of the Division of Militia Affairs, War Department, for duty in his office.

Wales, Philip G., major, ordered to proceed from Presidio of Monterey, to the Army General Hospital, San Francisco, for observation and treatment.

Johnson, Charles W.. 1st lieut., M. R. C., relieved from duty at Fort Des Moines, Iowa, and will proceed to his home, and on arrival there will report by telegraph to The Adjutant General of the Army, for further orders.

[illegible] major, ordered to report in person to [illegible] m P. Hall, Adjutant General, President, [illegible] ıshington, D. C., at such time as he may [illegible] by the board.

[illegible] major, on expiration of present leave of absence, directed to proceed to Manila, P. I., for duty on transport sailing from San Francisco, about May 5, 1910.

Raymond, H. I., lieut. col., will stand relieved from duty as Chief Surgeon, Headquarters, Department of Dakota, March 24, 1910, to enable him to comply with orders for the Philippine Islands.

Pulver, Arthur L., 1st lieut., M. R. C., ordered to proceed from Fort Porter to Fort Wadsworth, N. Y., for temporary duty.

McCallum, F. M., 1st lieut., M. R. C., honorably discharged from the service of the United States.

Tukey, William H., 1st lieut., M. R. C., orders to duty in the Philippine Islands, revoked; relieved from duty at Boise Barracks, Idaho, and will proceed to his home.

Public Health and Marine-Hospital Service

Changes for the week ended March 23, 1910:

Stoner, G. W., surgeon, granted 16 days' leave of absence from March 24, 1910.

Mead, F. W., surgeon, directed to proceed to Georgetown, S. C., on special temporary duty.

White, J. H., relieved as chairman of board of medical officers convened to meet April 4, 1910.

Carrington, P. M., surgeon, directed to proceed to San Francisco, on special temporary duty.

McIntosh, W. P., surgeon, detailed to represent the service at the meeting of the Association of American Medical Colleges, to be held in Baltimore, March 21-22, 1910.

Wickes, H. W., P. A. surgeon, relieved as recorder and detailed as chairman of board of medical officers convened to meet April 4, 1910.

Von Ezdorf, R. H., P. A. surgeon, leave of absence granted Jan. 19, 1910, amended to read 1 month and 6 days from Jan. 15 and 20 days from March 10, 1910.

Korn, W. A., P. A. surgeon, granted 2 days' leave of absence from March 22, 1910.

Pettyjohn, Joseph, P. A. surgeon, detailed as recorder of board of medical officers convened to meet April 4, 1910.

Hotchkiss, S. C., asst.-surgeon, granted 1 day's leave of absence in February, 1910, under paragraph 191, Service Regulations.

Dynan, N. J., acting asst.-surgeon, granted 4 days' leave of absence from Feb. 28, 1910, under paragraph 210, Service Regulations.

McKay, W. W., acting asst.-surgeon, granted 30 days' extension of leave from Feb. 5, 1910, on account of sickness.

Walkley, W. S., acting asst.-surgeon, granted 3 days' leave of absence from March 29, 1910.

Board of medical officers were convened to meet on April 4, 1910, for the purpose of making physical examinations of applicants for the position of cadet in the Revenue-Cutter Service, as follows: [illegible] Surgeon C. H. Gardner, chairman; Acting [illegible] D. MacMillan, recorder. Milwaukee, Wis., [illegible] chairman; Acting Assistant-Surgeon C. H. Stoddard, recorder.

Board of medical officers convened to meet at Boston, for the purpose of reexamination of an alien. Detail for the board: Passed Assistant Surgeon T. W. Salmon, chairman; Acting Assistant-Surgeon M. V. Safford; Acting Assistant-Surgeon H. B. C. Riemer, recorder.

Texas, State Medical Association of, Dallas, May 10-12.

ASSOCIATION OF AMERICAN MEDICAL COLLEGES

Twentieth Annual Meeting, held at Baltimore, March 21-22, 1910

DR. GEORGE HOWARD HOXIE, University of Kansas, the President, in the Chair

Officers Elected

The following officers were elected: President, Dr. J. A. Witherspoon, Vanderbilt University; vice-presidents, Dr. Horace D. Arnold, Tufts College Medical School, and Dr. Charles R. Bardeen, University of Wisconsin; secretary-treasurer, Dr. Fred C. Zapffe, University of Illinois, reelected;

judicial council, Drs. William J. Means, Starling-Ohio Medical College, Randolph Winslow, University of Maryland, and J. R. Guthrie, University of Iowa.

Amendments Adopted

The following amendments to the Constitution were adopted:

Article III, *Section* 1 (b): For the present Latin requirement of 2 years (4 points), there may be substituted 4 years of either high-school French or German, or its full equivalent, provided a satisfactory examination is passed in the elements of Latin grammar.

Article III, *Sec. 5:* Each annual course must be of not less than 32 weeks' duration instead of 30 weeks, as heretofore. This time includes examination periods, but does not include any vacation period. It was estimated that about 2 weeks would be consumed by examinations, leaving 30 actual teaching weeks, and on this basis the new curriculum is established.

Article III, *Sec. 13:* No college a member of this Association will be permitted to employ a paid solicitor for the purpose of inducing the attendance of students, nor shall any college offer to anyone, either directly or indirectly, any reward or inducement for securing the attendance of students.

Article III, *Sec. 1* (c): The university matriculation certificate of the Association of American Universities may be accepted as a minimum requirement for admission.

President's Address: Medical Standards; Medical Pedagogics

Dr. George Howard Hoxie, Kansas: The membership of the association is determined by a curriculum standard; it would be unwise to raise that standard beyond the reach of any school in membership; on the other hand, the legislatures of several states have adopted this standard. Schools of medicine are designed primarily for the education of practitioners of medicine. So-called research work must take a subordinate place in the average medical school. The average quality of the profession would be raised, however, by decreasing the number of practitioners. The ultimate standard will be 8 years of primary and grade schools, 4 years of high-school, 2 years of college, 4 years in a medical school, and 1 year in a large, well-regulated hospital. A boy entering the primary school at the age of 6 will be ready to begin the practice of medicine at 25, a mature age. Inquiry among the colleges in membership elicited the fact that the two-year college entrance standard seems to be the ultimate goal.

As to the length of the course, there was some difference of opinion as to whether this should be 4 or 5 years. One way out of the difficulty would be to have 2 degrees in medicine, as is now true of engineering, bachelor of medicine and doctor of medicine. To adopt the international standard as a minimum at this time would be disastrous. Medical education in America is as yet in a chaotic state. We are in a transition period, when the forms and methods of work are being differentiated and crystallized. To make the association national in scope we must not limit our membership by setting up standards that cannot be reached by some sections of our country. In other words, we must have a minimum rather than an ideal standard. It would be wiser to base standards of membership on the quality of work done in the schools and the character of the men who dictate the policy of the schools rather than on the quantitative standards. Does the school demand as high standards as its environment will permit? Does it make the most out of the material given? Furthermore, we cannot go forward more rapidly than the people and the state governments are ready to support us. The student who has had the broad training that includes the humanities as well as the sciences may lack some of the knowledge of the details of technic possessed by those who study only the sciences, but he will have the freshness and eagerness for work and a perspective that will more than compensate, even while in the medical school, for their lack. I would urge that the preliminary college years now being added to our courses be directed toward making men rather than artisans; that the languages, philosophy and the arts be given a proportionate place in their curriculum.

It seems wiser not to take radical action at this time on standards, but to continue our present standard. I believe that the association is concerned not so much with the legal and economic aspects of medical education, as with its pedagogics. We should not give so many hours of study that the students will be physically exhausted, nor should we give so much mental labor that the students become stale. Many medical schools do not require preparation for their class exercises. We should define our standards more carefully. An hour should mean a class exercise and therefore we should make clear in our statement whether the hours enumerated are total hours of study or simply hours of classroom exercise. The curriculum can be improved by giving attention to the law of variety and monotony. Each day the student should have exercises of sufficient variety to excite his attention, but not so many as to dull his interest. I would suggest that we try to arrange our clinical curriculum along the line of the three great branches of practice: medicine, surgery and obstetrics and gynecology. The clinical laboratory should not be a separate department, but a phase of the work in all the departments mentioned. The curriculum of the clinical department must center about the hospital. No school of medicine is adequate for present-day needs unless it is possessed of a hospital of its own. Clinical teaching should be practical and not irrelevant. I would suggest that we work in harmony with other organizations now interested in medical education; that we take their suggestions and recommendations and examine them in the light of our own experience, and in the light of pedagogics.

Report of Secretary

Dr. Fred C. Zapffe, Chicago: The present membership of the association numbers 51, and cannot be increased very materially because of apparent ineligibility. The Council on Medical Education of the American Medical Association placed in its acceptable list 68 colleges. The work the council is doing is of the very greatest importance in its particular sphere, and thorough and hearty cooperation between the council and this association is greatly to be desired. To further such cooperation, I would suggest that the next annual meeting of the association be held in conjunction with the annual conference of the council, in Chicago, or elsewhere, as may be decided later. By a constitutional provision, this association must hold its meeting on the third Monday in March, but it is probable that the council is in a position to shift its time of meeting.

(To be continued)

MEDICAL SOCIETY OF THE MISSOURI VALLEY

Twenty-second Semi-Annual Meeting, held at Omaha, March 17-18, 1910

(Concluded from page 1075)

Should Operation for Ruptured Tubal Pregnancy Be Immediate or Deferred?

Dr. John E. Summers, Omaha: In the majority, say about 95 per cent., of cases of ruptured tubal pregnancy, no operation should be done until reaction from the shock of rupture has taken place. In the remaining 5 per cent. of these cases no delay is permissible. The urgency for operation can be recognized in most patients by the differences in the initial symptoms. In borderline cases the same rules of recognition apply. A differentiation must be made between hemorrhage and shock, immediate and recurring.

DISCUSSION

Dr. B. B. Davis, Omaha: I have done many of these operations; many of these patients will go through the original hemorrhage and shock and will rally and be in a much better condition for operation than at the beginning of the hemorrhage. For a long time I took the position that ruptured tubal pregnancy ought to be operated on at once, but for the last two or three years I have delayed operation for at least a few hours.

Dr. O. Beverly Campbell, St. Joseph, Mo.: I believe that every case of ruptured ectopic gestation is a law unto itself, and the judgment of the surgeon should be used. In many of these cases, delay in operating is indicated. My experience has been that in most cases a blood clot will form and hemorrhage cease, and that we should wait until shock has passed off and the patient has reacted before operating.

DR. DONALD MACRAE, Council Bluffs, Iowa: I am not in a position to differentiate between one case and another, and to say that this patient is or is not in a serious condition, and so in cases of ruptured tubal pregnancy I am going to operate as soon as I can, as I do not know which case is going to terminate fatally, and which is not.

The Physical Basis of Mental Disease

DR. FRANK P. NORBURY, Hospital, Ill., delivered the oration in medicine, and, among other things, said:

The interrelationship of mind and body will ever be a fruitful field for discussion, and may never be solved to the satisfaction of all, but the time is coming, and is not far distant, when the somatic will have precedence over purely mental symptoms. Our therapeutics must and will be adjusted to meet the conditions as they are, not as they are supposed to be.

Local Anesthesia

DR. LEONARD FREEMAN, Denver, delivered the oration in surgery. He referred to the early history of chloroform and ether and the dangers attending the administration of these anesthetics. Nervous and hysterical patients are not suitable for local anesthesia. The patients, he said, must be selected with care and the surgeon must consider age, temperament, nervous control of the individual, etc. Among the operations which can be done under local anesthesia he mentioned the removal of tumors of the scrotum, castrations, epididymectomies, varicocele and hydrocele operations.

Rapid and Complete Cure of Gonorrhea

DR. THOMAS M. PAUL, St. Joseph, Mo.: A cure is not complete unless it results in the absolute eradication of gonococci from the genito-urinary tract, and such a cure can never be rapid in the sense in which that term is used by the laity.

Why the Indifference of the Profession to Morphinism Should Be Changed

DR. S. GROVER BURNETT, Kansas City, Mo., described three types: 1. Simple morphinists belong to the better class of mentalities. They inherit or acquire a tendency to nerve weakness by exhaustive taxations of nerve energy. The drug is taken to relieve physical and exhaustive nerve discomfort. 2. Morphinomaniacs are lower in intellectual stability and acquirements. The inherited weakness of nerve and mind energy is the rule, and a predisposition to add acquired exhaustive states is strong. The drug is taken to relieve exhaustive psychic pain, mind pain, mind discomforts. The action of the drug is to cause further mind deterioration in a mind already near the borderline of insanity. 3. Delusional or motiveless morphinists are sufficiently over the borderline of insanity to cause them to take the drug because of faulty mind, delusional states. The condition is apt to end in a terminal insanity.

Treatment of Localized Appendicular Abscess

DR. VAN BUREN KNOTT, Sioux City, Iowa: The removal of the appendix at a secondary operation is frequently difficult because of the density of the surrounding adhesions and in the majority of instances it will be found much easier to remove it at the first operation; and this should be done rather than subject the patient to a prolonged and often serious operation. The incision is invariably made through the right rectus muscle, splitting the fibers and the peritoneal cavity freely open. A small gauze pack is tucked into the upper angle of the wound and so adjusted as to prevent any extravasation of pus toward the liver or diaphragm. Another small pack is tucked in toward the median line from the upper angle of the wound to the lower pelvis to prevent any extravasation toward the left. The abscess cavity is then freely opened with the fingers, unless opened by the peritoneal incision, and the pus is rapidly mopped up with gauze sponges. The appendix is then exposed and removed. All adhesions separating the abscess cavity from the lower pelvis are freely separated and the pus or seropus, which is usually found in the lower peritoneal pouch, is rapidly mopped up with sponges. A large split rubber tube, from one-half inch to one inch in diameter and carrying a wick of iodoform gauze is inserted through the lower angle of the wound to the bottom of the rectovesical pouch, or cul-de-sac, the protecting gauze removed and the wound closed down to the tube with interrupted through-and-through silkworm sutures. A large-size tube is important, as I believe that the first two hours of drainage are those which count. This method is not advocated for the occasional operator, but for men of great experience.

Increasing Mortality in the United States from Heart, Brain and Kidney Lesions

DR. W. F. MILROY, Omaha, directed attention to the enormous increase of deaths from these diseases and offered suggestions as to what may be done by way of remedies.

Treatment of Angiomata and Nevi

DR. JOHN PRENTISS LORD, Omaha: The angiomata fall within the pale of surgery, while nevi, involving the skin only, fall within the sphere of dermatology. The conditions are so frequently associated that it becomes impossible to divide their treatment. Boiling water is of great value in treatment of angiomata and carbon dioxid snow in treatment of pigmented hairy nevi.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

Senator Owen Declares in Favor of a Department of Health

Hon. Robert L. Owen, United States Senator from Oklahoma, delivered a speech in the United States Senate, Thursday, March 24, in support of Senate Bill 6049, introduced by him, providing for a Department of Public Health. Senator Owen stated that the present loss of life from preventable diseases in the United States amounts to over 600,000 lives per annum, while the economic loss amounts to over $2.000,000,000. After calling attention to the report of the Committee of One Hundred compiled by Prof. Irving Fisher, with the assistance of many well-known scientific men as his authority for these statements, Senator Owen discussed in detail the possibilities of the prolongation of life, the prevention of yellow fever, hookworm disease, bubonic plague, and other contagious diseases. He then read the letter from Dr. Charles A. L. Reed, chairman of the Committee on Legislation of the American Medical Association, which appeared in THE JOURNAL March 19, and quoted from President Taft, Mr. Roosevelt and others as to the necessity and importance of public health legislation. Senator Owen's argument for the establishment of a department instead of a bureau is of particular interest. He said:

> It is generally agreed that these bureaus should all be brought together as one working body. To bring established bureaus under a new "bureau of public health" would be to lower the dignity of the present bureaus by making them the subordinate bureaus of a new bureau, which would be offensive to every bureau so subordinated.
>
> To bring these bureaus under a department would not lower the prestige of a bureau thus coordinated with other bureaus under the department, and would, I believe, generally meet the approval of the government officers employed in the various bureaus so coordinated, giving them a new dignity by being a distinct branch of a department of public health, through which they could enlarge their efficiency and find better expression *and publicity of* work done for the public health.
>
> We have had bureaus for one hundred years. They are scattered in eight departments. They have been disconnected and without coordination. They have ever been jealous of each other, the one nullifying and hampering the work of another. They have been without a responsible head because of this subdivision and because the chief of the most important of these bureaus, the Surgeon-General of the Public Health and Marine-Hospital Service, *cannot* express an opinion or give information until he has consulted the Secretary of the Treasury.

BUBONIC PLAGUE ON THE PACIFIC COAST

Regarding the effect of control of the quarantine service by the Secretary of the Treasury, Senator Owen instanced the history of the epidemic of bubonic plague in San Francisco:

When the bubonic plague broke out in San Francisco in 1900—one of our importations from the Orient, known in former times as the black death or the plague—the city board of health of San Francisco quarantined the Chinese district. [It is the most deadly epidemic disease known to men. In the outbreak in Bombay 220,000 cases gave 164,000 deaths. This disease, as the black death, killed 68,596 people in London in 1665, nearly half of those who remained in the city.] The United States circuit judge, on June 15, 1900, influenced by the commercial spirit of San Francisco, declared the city quarantine illegal, gratuitously observing in his opinion:

"If it were within the province of this court to decide the point, I should hold that there is not and never has been a case of plague in this city."

This high authority on bubonic plague would also have decided, "if within the province of his court, that there never would be a case in San Francisco." His judgment in the one case would be as persuasive as in the other.

Bubonic plague was then in the city. It is now scattered over the Pacific coast at points a thousand miles apart and is requiring enormous sums of money to stamp it out, and it has not been stamped out, but is now endemic and spreading through the infection of ground squirrels and rats, which continually infect each other and spread the germs of the disease over enlarging areas.

This opinion of the United States circuit judge was followed with an immediate federal quarantine of the State of California, which was the duty of the government officers in charge under the obligation of the United States to the several States of the Union and to the nations of the world. The Marine-Hospital Service officials in San Francisco declared this quarantine.

The governor of California, the senators of California, and the commercial bodies of San Francisco immediately suppressed the Marine-Hospital Service report, compelled the Surgeon-General to yield, proved a false case, and made it temporarily stand as the truth before the country. They furnished evidence and proved (?) that there was no bubonic plague in San Francisco, nothwithstanding the fact bubonic plague was there in sober truth.

The Marine-Hospital Service finally persuaded the Secretary of the Interior to cause an inquiry in January, 1901, through experts of the highest class. This unanswerable authoritative report was made on Feb. 26, 1901, finding numerous cases of bubonic plague in the heart of San Francisco. The United States quarantine law (sec. 4) required its immediate publication. It was suppressed until April 19, 1901, and until it had been given publicity by the *Occidental Medical Times*, The Journal of the American Medical Association, the *Medical News*, and the *Sacramento Bee*.

Again the commercial interests of San Francisco triumphed over the bureau and compelled the Surgeon-General, the head of the bureau, by an order of his superior officer, the Secretary of the Treasury, to agree to suppress this report, contrary to the obvious moral and sanitary duty of the United States. From that time bubonic plague has widened the area of its terribly dangerous infection from Los Angeles to Seattle, passing from rat to rat and squirrel to squirrel and from these animals to an occasional human being through the agency of the common flea. Various experts of the Marine-Hospital Service, who immediately after the report of 1901 discovered the infection outside of San Francisco and reported the truth, were by some strange fatality shortly after their several reports removed from such duty faithfully performed and sent to the ends of the world—to Honolulu, to Ecuador, and so forth.

It is a most interesting history, the details of which might with propriety be given to the Senate as showing the destructive power commercial interests can exert over the faithful servants of a subordinate bureau.

Senator Owen then argued that a Department of Public Health is absolutely essential in order to comply with the international sanitary obligations of the United States, as a bureau which is subordinate to a department is not in a position to represent the United States in international sanitary affairs. He called attention to the International Sanitary Convention of American Republics held in Washington, Dec. 2-4, 1902, which pledged the respective health organizations of the various American republics participating to cooperate for the suppression of contagious diseases, and urged that a bureau has been tried in the balance and found wanting, and that the importance of the subject, the dignity and honor of the United States, its international relations and the health and welfare of the world demand the establishment of a Department of Health.

Senator Owen then reviewed the present cost of health agencies in the United States, showing that a sum of nearly $15,000,000 is being expended by the government and that over 12,000 persons are employed. He also showed by quotations from the various party platforms, reports of committees, and other sources, that the people are ready to support such a movement, closing his address as follows:

This is a question of vast national importance. In eight years we have increased our expenditures over the average of preceding years by the huge sum of one thousand millions for the Army and Navy, and are spending 70 per cent. of the national income to cover the obligations of past wars and the preparations for possible future war, or about seven hundred millions per annum. But for war on preventable disease now costing us infinite treasure in life, efficiency, and commercial power and prestige we spend nothing and do not even employ the agencies we have in an efficient manner.

In the name of the people and in the name of the American Medical Association, whose members are the faithful and self-sacrificing guardians of the health of our people, and in the name of the Committee of One Hundred, of the American Federation of Labor, of the National Grange, and of the various health boards of the forty-six states of the Union and of the great body of learned men desiring improved sanitation and the application of the improved agencies of preventing disease, disability, and death, I pray the Senate to establish a department of public health.

The principle of the bill meets the general approval of the public-health societies and of the medical associations of the United States, and there should be no difficulty in perfecting this bill and in impressing on the country the importance of organized effort to control the ravages of tuberculosis, typhoid and malarial fevers, bubonic plague, and other preventable diseases, which inflict such enormous injury on the people of the United States, impose such vast, but needless, human misery and pain, with great financial loss and loss of prestige and power.

A commercial nation will not be unmindful of the commercial value of the saving of life and efficiency possible, which is worth $3,000,000,000 per annum.

A humane nation will not fail to act when it is known that we could save the lives of 600,000 of our people annually, prevent the sickness of 3,000,000 of people per annum, who now suffer from preventable disease, and greatly abate the volume of human pain, misery, and death.

I trust, Mr. President, that the Senate may not fail to take action in regard to this matter at the present session.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
Bowling Green, Kentucky

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Eighth Month—Third Weekly Meeting

Pharmacologic and Therapeutic Actions of Drugs (Continued)

VII. Drugs Acting on Bodily Heat: A. Drugs which decrease bodily temperature, antipyretics. Thermogenesis, thermolysis, thermotaxis. 1. Drugs increasing loss of heat. 2. Decreasing production of heat. B. Drugs which cause rise of temperature.

VIII. Drugs Acting on Respiration: A. Drugs altering composition of air, by inhalation. 1. Drugs acting generally, anesthetics, amyl nitrite, etc. 2. Drugs stimulating bronchial secretion. 3. Drugs disinfecting foul secretions. 4. Relieving spasm of bronchial tubes. B. Drugs acting on respiratory centers. 1. Stimulants. 2. Depressants. C. Drugs affecting bronchial secretion. 1. Increasing. 2. Diminishing. 3. Disinfecting. D. Drugs relaxing spasm of bronchial tubes, asthma, etc. E. Expectorants. 1. Stimulating. 2. Depressing.

IX. Drugs Acting on Digestive Apparatus: A. Drugs acting on flow of saliva. 1. Sialagogues, act by (a) stimulation of secretory cells, or nerve terminals in them, (b) stimulating afferent nerves, in mouth or in stomach. 2. Antisialagogues, act by depressing (a) secretory cells and nerve terminals, or (b) afferent nerves. B. Drugs acting on stomach. 1. Increasing amount of gastric juice secreted. 2. Decreasing amount of gastric juice secreted. 3. Drugs altering composition of gastric contents. 4. Drugs which dilate vessels of stomach. 5. Drugs which contract vessels of stomach. 6. Drugs acting on nerves of stomach. 7. Drugs acting on movements of stomach. 8. Emetics. Act locally or centrally. 9. Antiemetics. Direct or indirect.

C. Drugs acting on intestines. 1. Purgatives. Laxatives, simple purgatives, cathartics, cholagogues. 2. Intestinal antiseptics. 3. Intestinal astringents. (a) Acting on vessels, (b) coagulating albuminous fluids, (c) diminishing amount of fluid secreted, (d) lessening muscular contractions.

Marriages

Jacob Kulis, M.D., to Miss Edith A. Olsjewski, both of Chicago, recently.

Francis W. McNamara, M.D., to Mrs. Ella May Eldredge, both of Chicago, March 19.

William Leon Channell, M.D., to Miss Edna Ingram, both of Oakland, Cal., March 16.

E. Don Taylor, M.D., Watertown, Ill., to Miss Katie Swanson of Colona, Ill., at Moline, March 16.

Marano Bernardo del Carmen Caballero, M.D., Porto Rico, to Miss Cecil Beatrice Mallory, at Petersburg, Va., March 17.

Deaths

Fred Byron Robinson, M.D. Rush Medical College, Chicago, 1882; a noted scientific investigator in anatomy and pathology; some-time professor of anatomy and clinical surgery in Toledo Medical College; professor of anatomy in the Post-Graduate Medical School and Hospital, Chicago; professor of surgery in the College of Physicians and Surgeons, Chicago; for thirteen years professor of gynecology and abdominal surgery in Illinois Medical College; professor of gynecology and diseases of the abdominal viscera in the Chicago College of Medicine and Surgery; a member of the Illinois State Medical Society; a man of boundless enthusiasm in the field of original research; a prolific writer; author of two volumes on intestinal surgery, four volumes on gynecologic subjects, an encyclopedic treatise on the peritoneum, and an extensive work on "The Abdominal and Pelvic Brain;" died at his home in River Forest, March 23, from disease of the kidney, aged 53.

Oliver Morse Dewing, M.D. College of Physicians and Surgeons, New York City, 1887; a member of the Medical Society of the State of New York, Associated Physicians of Long Island and American Medico-Psychological Association; formerly assistant physician in the New York Insane Asylum; transferred in 1889 to the Kings County Insane Asylum, of which he was made superintendent in 1892; appointed medical superintendent of that institution when it became a state hospital; and in 1897 made general superintendent of the Kings Park and Flatbush Insane Asylums; superintendent of the Long Island State Hospital, Flatbush; an acknowledged expert on treatment of the insane and asylum management; died at the State Hospital, Flatbush, March 15, from lobar pneumonia, aged 47. At a meeting of the staff of the hospital, March 22, resolutions of regret and sympathy were adopted.

Franklin Bennett Entrikin, M.D. Medical College of Ohio, Cincinnati, 1894; of Findlay, Ohio; a member of the American Medical Association and Association of Military Surgeons of the United States; formerly surgeon of the Second Infantry, Ohio N. G.; a member of the local pension examining board; oculist and aurist and a member of the consulting staff of the Findlay Home and Hospital; died in the Jewish Hospital, Cincinnati, March 16, from acute nephritis, after an operation for umbilical hernia, aged 38.

Orlando Scott Wood, M.D. Starling Medical College, Columbus, Ohio, 1891; College of Physicians and Surgeons, Baltimore, 1900; of Haydenville, Ohio; for six years a member of the staff of the Athens State Hospital, and for one term a trustee of the institution; surgeon of volunteers during the Spanish-American War, with service in Cuba; died in Mount Carmel Hospital, Columbus, March 14, from septicemia, due to an operation wound, aged 46.

Joseph W. Eddy, M.D. Detroit Medical College, 1874; a member of the American Medical Association and Syracuse Academy of Medicine; staff surgeon to the Oswego City Hospital; local surgeon of the New York Central System, and since 1886 chief surgeon to the Rome, Watertown and Ogdensburg division of that system; died at his home in Oswego, March 12, from acute bradycardia following cystitis and nephritis, aged 58.

Charles Peyton Gordon, M.D. New York University, New York City, 1860; surgeon in the Confederate service throughout the Civil War; a member of the Association of Surgeons of the Southern Railway Company and International Association of Railway Surgeons; for more than twenty years local surgeon of the Southern Railway at Dalton, Ga.; died at his home, March 16, from heart disease, aged 73.

William S. Wood, M.D. McGill University, Montreal, 1896; a member of the American Medical Association and Minnesota Valley Medical Association; a specialist on diseases of the eye, ear, nose and throat of Blooming Prairie, Minn.; died at the home of his father in Faribault, Minn., March 16, from pulmonary tuberculosis, following an infection of the throat, aged 36.

Arthur Delavan Stowitts, M.D. Albany (N. Y.) Medical College, 1886; a member of the American Medical Association; of Sidney, Neb.; local surgeon for the Union Pacific and Burlington systems; a member of the local board of United States Pension Examiners; died in the Methodist Hospital, Omaha, March 13, after an operation for mastoid disease, aged 48.

Henry Rhode, M.D. University of Goettingen, Germany, 1850; said to have been the oldest practitioner of Brown county, Wis.; at one time a surgeon in the Prussian army; physician of Brown county for several years, and a member of the pension examining board of Green Bay; died at his home in that city, March 16, from pneumonia, aged 80.

Ira Hudson Fry, M.D. Hahnemann Medical College, Chicago, 1881; a specialist on diseases of the eye, ear, nose and throat of Marshalltown, Iowa; while suffering from melancholia, is said to have committed suicide by hanging himself in an empty store building in Marshalltown, March 10, aged 51.

Raymond B. Harris, M.D. Savannah (Ga.) Medical College, 1859; assistant surgeon of the First and Fifty-seventh Ga. Infantry, C. S. A., during the Civil War; state senator in 1880 and 1881; an alderman of Savannah from 1889 to 1893; died at his home, March 15, from heart disease, aged 71.

John A. Hutchinson, M.D. Bennett Medical College, Chicago, 1878; a veteran of the Civil War; and at one time a member of the local pension examining board of New Haven, Conn., and later a resident of Cambridge, Mass.; died in the Soldiers' Home, Chelsea, Mass., March 13, from nephritis, aged 66.

Cyrus V. Gorrell, M.D. Fort Wayne (Ind.) College of Medicine, 1884; of Payne, Ohio; formerly a member of the American Medical Association; a member of the Ohio State Medical Association; died suddenly in the caboose of a freight train near Payne, March 7, from heart disease, aged 66.

Joel G. Williams, M.D. University of Missouri, Columbia, 1856; a member of the Illinois State Medical Society; assistant surgeon of the Second Illinois Volunteer Cavalry during the Civil War; died in a cottage at the Soldiers' Home, Quincy, March 17, from heart disease, aged 75.

John M. Coombs, M.D. Cincinnati College of Medicine and Surgery, 1865; a member of the Ohio State Medical Association; acting assistant surgeon in the Army during the Civil War; auditor of Defiance county, Ohio, in 1893; died at his home in Hicksville, March 13, aged 77.

Wade Hampton Barnett, M.D. University of Louisville, 1898; a member of the American Medical Association; a charter member and president in 1905 of the Williamson County (Tenn.) Medical Society; died at his home near Franklin, Tenn., February 28, from tuberculosis, aged 36.

Evans E. Brubaker, M.D. Starling Medical College, Columbus, 1878; a member of the American Medical Association; and local surgeon of the Chicago, Milwaukee and St. Paul Railway; died at his home in Northfield, Minn., January 6, from cancer of the liver, aged 56.

James McCann, M.D. Western Reserve University, Cleveland, 1856; of Normal, Ill.; formerly a member of the local pensioning examining boards of Joliet and El Paso, Ill.; died in the Kelso Sanitarium, Bloomington, March 18, from ptomain poisoning, aged 77.

Willis Anderson Barclift, M.D. University of Tennessee, Nashville, 1878; a member of the Medical Association of the State of Alabama; died at his home in Hartsells, March 14, after an operation performed at a hospital in Birmingham, aged 57.

Clarence W. Pickerill, M.D. Iowa Eclectic Medical College, Des Moines, 1892; of Kansas City, Mo.; formerly a member of the American Medical Association; died at the home of his parents in Lake Charles, La., February 20, from tuberculosis, aged 38.

David Allison Armfield, M.D. Jefferson Medical College, 1861; a member of the Medical Society of the State of North Carolina; for ten years United States pension examiner; died at his home in Jamestown, March 1, from pneumonia, aged 73.

William Herbert Nickelson, M.D. Hahnemann Medical College, Chicago, 1881; visiting physician to Syracuse Homeopathic Hospital; health officer of Adams, N. Y.; died in his office in that place March 14, from heart disease, aged 51.

Townsend A. Walker, M.D. University of Buffalo, N. Y., 1897; a member of the Medical Society of the State of New

York and Buffalo Academy of Medicine; died at his home in Corning, March 10, from cerebral hemorrhage, aged 40.

Hugh Alexander Utley, M.D. University of Nashville, Tenn., 1878; of Goodlettsville, Tenn., and vice-president of the National Bank of that place; died in an infirmary in Nashville, March 11, after a surgical operation, aged 56.

Warren Thomas Thornton, M.D. University of Kansas, Lawrence, 1908; a member of the staff of the Kansas City General Hospital; died in that institution, March 17, from septicemia, following a peritonsillar abscess, aged 26.

George T. Blynd, M.D. Northwestern University Medical School, Chicago, 1904; a member of the State Medical Society of Wisconsin; died at his home in Berlin, March 18, from tubercular meningitis, aged 34.

Walter Channing Blaisdell, M.D. Harvard Medical College, Boston, 1867; a member of the Massachusetts Medical Society; died at his home in Everett, Mass., Nov. 14, 1909, from acute enterocolitis, aged 65.

Myron Pelaski Fogleson, M.D. Bennett Medical College, Chicago, 1886; a member of the Michigan State Medical Society; died at his home in Harvard, January 23, from acute yellow atrophy of the liver.

Frank B. Hamilton, M.D. University of Nashville, 1867; a member of the Tennessee State Medical Association; a Confederate veteran; died at his home in Jackson, March 11, from rheumatism, aged 68.

Chester Carey, M.D. Long Island College Hospital, Brooklyn, 1881; a practitioner of Columbiaville, Mich., for thirty-five years; died at the home of his brother in Adrian, Mich., March 16, aged 62.

George L. Cunningham, M.D. University of Louisville, 1876; a pioneer practitioner of Conway county, Ark., and president of the bank of Morrillton; died at his home in that city, March 11, aged 76.

Hiram Newton Whitacre, M.D. Medical College of Ohio, Cincinnati, 1878; a member of the American Medical Association; died at his home in Carbondale, Ill., March 19, from pneumonia, aged 62.

Roswell Delavan Smith, M.D. New York Homeopathic Medical College, New York City, 1880; for many years a clergyman; died at his home in New York City, March 19, from asthma, aged 76.

John O. Dixon, M.D. Missouri Medical College, St. Louis, 1886; a member of the American Medical Association; died suddenly at his home in Marion, Ky., March 16, from heart disease, aged 49.

H. R. Trollinger (license, years of practice, Ohio, 1896); for fifty years a practitioner of Homeworth, Ohio; died at his home in that place, March 8, from cerebral hemorrhage, aged about 85.

Thomas Stuart Farrar, M.D. Trinity Medical College, Toronto, 1885; of Cedar Rapids, Iowa, was stricken with cerebral hemorrhage, on the street, March 18, and died, aged 49.

Fred W. Beil, M.D. Western Pennsylvania Medical College, Pittsburg, 1899; formerly of Sharon, Pa.; died at his home in Pittsburg, March 12, from tuberculosis, aged 35.

Valentine H. Hobson, M.D. Hospital College of Medicine, Louisville, 1889; of Richmond, Ky.; died in Lexington, Ky., March 15, from the effects of a fall from a window.

John G. MacNamara, M.D. Rush Medical College, 1884; of South St. Paul, Minn.; died suddenly in St. Joseph's Hospital, St. Paul, March 11, from heart disease, aged 55.

William Willet Moon, M.D. University of Vermont, Burlington, 1892; died at his home in Brooklyn, March 15, from pleurisy, complicating rheumatic fever, aged 40.

Greenbury Linton Shipp, M.D. University of Maryland, Baltimore, 1885; of Little Hocking, Ohio; died suddenly in that place, January 3, from heart disease, aged 47.

J. O. K. Gant, M.D. Washington University, St. Louis, 1865; a member of the Missouri State Medical Association; died at his home in Plattsburg March 8, aged 68.

William Benjamin Smith, M.D. Medical College of Ohio, Cincinnati, 1873; died at his home in Downing, Mo., March 3, from cerebral hemorrhage, aged 65.

William F. Walker, M.D. New York University, New York City, 1852; died at his home near Aberdeen, Miss., March 19, from paralysis, aged 82.

William Gregory Hea[illegible]ley, M.D. Albany (N. Y.) Medical College, 1899; died at his home in Cohoes, N. Y., March 15, aged 30.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

ARIZONA: Phoenix, April 4-5. Sec., Dr. Ancil Martin.

CALIFORNIA: San Francisco, April 5. Sec., Dr. Charles L. Tisdale, 929 Butler Building.

COLORADO: Denver, April 5. Sec., Dr. S. D. VanMeter, 1723 Tremont Place.

FLORIDA: Jacksonville, April 4-5. Sec., Dr. J. D. Fernandez.

IDAHO: Boise, April 5. Sec., Dr. O. J. Allen, Bellevue.

ILLINOIS: Chicago, April 14-16. Sec., Dr. J. A. Egan, Springfield.

MINNESOTA: State University, Minneapolis, April 5. Sec., Dr. W. S. Fullerton, 214 American Nat'l Bank Bldg., St. Paul.

MONTANA: The Capitol, Helena, April 5. Sec., Dr. W. C. Riddell.

NEW MEXICO: Santa Fe, April 11-12. Sec., Dr. J. A. Massie.

OKLAHOMA: Ione Hotel, Guthrie, April 12. Sec., Dr. Frank P. Davis, Enid.

RHODE ISLAND: State House, Providence, April 7-8. Sec., Dr. Gardner T. Swarts, Room 315, State House.

WEST VIRGINIA: Wheeling, April 12-14. Sec., Dr. H. A. Barbee, Point Pleasant.

Iowa December Report

Dr. G. H. Sumner, secretary of the Iowa State Board of Medical Examiners, reports the written examination held at Des Moines, December 7-9, 1909. The number of subjects examined in was 8; percentage required to pass, 75. The total number of candidates examined was 8, of whom 3 passed and 5 failed. Thirteen reciprocal licenses were issued. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
George Washington University	(1908)	87.1
Sioux City College of Medicine	(1909)	81.1
University of Toronto, Ontario	(1908)	85.2

FAILED

College	Year Grad.	Per Cent.
University of Iowa, College of Medicine	(1909)	70.1
Keokuk Medical College, College of Phys. and Surg.	(1900)	72
Sioux City College of Medicine	(1909)	74.3
Rush Medical College	(1892)	68.1
St. Louis College of Physicians and Surgeons	(1909)	68.6

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
College of Physicians and Surgeons, Chicago	(1894) Wisconsin; (1905) (1906)	Illinois
Northwestern University Med. School	(1908) (2, 1909)	Illinois
Hahnemann Medical College and Hosp., Chicago	(1907)	Illinois
Keokuk Medical College	(1894)	Kansas
University of Louisville	(1909)	Illinois
University of Michigan, College of Medicine	(1908)	Michigan
Creighton Medical College	(1903) (1905) (1909)	Nebraska

Salicylate Treatment of Bacillus-Carriers.—How to free typhoid bacillus-carriers from their dangerous guests is a question which R. Hilgermann of Coblenz thinks can be solved by administering to them some drug that is readily eliminated by all the secretions, renders the bile more fluid and increases its amount, while it has a certain bactericidal action but is free from toxic action, even when taken for long periods. In a communication on the subject in the *Klinisches Jahrbuch*, 1910, xxii, 291, he announces that sodium salicylate fulfils all these conditions, and that he has successfully used it for the purpose in 3 cases. The bacillus-carriers in question were in the Andernach insane asylum and he gave the salicylate in 1 gm. (15 grain) doses three, four or five times a day for a week at time, giving five courses in one year in one case. The stools became entirely free from typhoid bacilli after the third course and none has been found during the nearly two years since. After even one course of the salicylate the number of typhoid bacilli rapidly diminished and those found displayed very little vitality. Experimental research has confirmed these clinical findings justifying the hope, he believes, that a course of sodium salicylate after recovery from typhoid would clear out remaining bacilli and prevent the individual's becoming a chronic bacillus-carrier. In his cases the carriers had sheltered the bacilli for so many years that it was far more difficult to dislodge them than would be the case with comparatively recent typhoid infection. The salicylate does not display such powerful bactericidal action in respect to paratyphoid bacilli.

Book Notices

ARTHRITIS DEFORMANS: COMPRISING RHEUMATOID ARTHRITIS, OSTEO-ARTHRITIS, AND SPONDYLITIS DEFORMANS. By R. Llewellyn Jones, M.B., Fellow and Member of Council of British Balneological and Climatological Society. Cloth. Pp. 353, with 38 Illustrations. Price, $4 net. New York: William Wood & Co., 1909.

This book is a most interesting and valuable contribution from the viewpoint of a former medical officer of the Royal Mineral Water Hospital of Bath, England, and comes very opportunely for consideration with the recent valuable work of Goldthwait, Painter and Osgood, and the still more recent paper by Nichols and Richardson in the *Journal of Medical Research* for September, 1909. The author says that his chief aim is to indicate and emphasize the essential distinctness of the two diseases, rheumatoid arthritis and osteo-arthritis. Special consideration has been given to the premonitory symptoms which characterize the period of invasion of rheumatoid arthritis, in the hope that it may assist in the early recognition of the affection so essential to its successful treatment. From the historical chapter one learns that there have been even more etiologic theories than names advanced for this disease or group of diseases; and with reason.

From the author's standpoint there are two distinct diseases, namely, rheumatoid arthritis and osteo-arthritis; whereas, we in America, viewing the condition somewhat more from the pathologic findings, include all under the term osteo-arthritis, and pathologically divide the cases into the atrophic and hypertrophic varieties, although the work of Nichols and Richardson has shown that identical pathologic findings clearly arise from a variety of causes, in fact from about all of the causes that have heretofore been regarded as etiologic factors.

We recommend the perusal of this book to all those interested in chronic non-tuberculous joint diseases; but we call attention to the fact that the author uses the terms "atrophic arthritis" and "hypertrophic arthritis" in the ordinary sense of obvious atrophy and hypertrophy of the joints, and not in the sense used by Nichol and Richardson, which is based on the microscopic findings in the joint structures. The historical references are most numerous and range from Cicero and Shakespeare down.

DISEASES OF CHILDREN. Translated by J. L. Salinger. Edited by Abraham Jacobi, M.D., LL.D., Consulting Physician Mt. Sinai, Bellevue and German Hospitals, etc. Pp. 828, with 34 illustrations. New York: D. Appleton & Co., 1910.

Perhaps no more accurate or illuminating statement could be made concerning the quality of this work by twenty-three German and Austrian authors than that of the editor. As he says, the articles are all written by masters of national or international renown, are evidently weighed with care and guided by learning, and are brief but complete and lucid. The list of authors includes such names as Czerny, Neumann, Hoffa, Henoch, Heubner, Baginsky, Escherich, C. Keller and others equally authoritative. The book is hardly in the usual text-book style, but each monograph is written in the complete and thorough manner of the Germans, and all coordinated, so that there is no overlapping in the treatment of the subjects. Among the unusually complete chapters is that on the diseases of the new-born, which includes a very interesting section on those infectious diseases which may be transmitted from the mother or father to the fetus. Other chapters are on infantile scurvy, rickets, syphilis, convulsions, infantile paralysis and scarlet fever. In a few instances the treatment is not very fully given, but is usually sufficiently complete. As is usual in foreign works, the work of American authors in pediatrics is not referred to except casually in a few instances, and the editor calls attention to this fact. This is partially compensated for, however, by careful, even critical editing by Dr. Jacobi, who adds a word or a phrase here and there to the text to modify a too dogmatic statement, or by way of criticism, or reference to work by Americans, and by full foot-notes in elaboration of management or treatment, or on some other phase, where it seems to be necessary. The book contains a number of charts and a few other illustrations. The translation under the supervision of Dr. Salinger is good and makes a very readable book. Aside from the preference of some for a text-book by a single author, the work is an eminently satisfactory one on the subject.

THE CAMPAIGN AGAINST MICROBES. By Etienne Burnett, M.D., of the Pasteur Institute; Head for the Vaccination Service of the City of Paris. Translated from the French by E. E. Austin, F.Z.S. Cloth. Pp. 248. Price, $2.25 net. New York: William Wood & Co., 1909.

This work consists of 227 pages. The subjects treated are cancer, tuberculosis, tetanus, sleeping-sickness, enteritis and variola: the original article by Jenner on vaccination is added as an appendix. The subjects are treated in a semi-popular way, and yet the method is a little too technical, at least for the general American reading public. It will appeal to medical men who wish to be instructed and entertained and to the better informed people who have had some technical training. The literature is freely drawn on.

In discussing cancer the author lays especial stress on the possible contagiousness of the disease, and quotes freely from experiences of himself and others to show that there is a relation between such etiologic factors as soil moisture, dirty vegetables and contact with affected individuals in cancer. In considering tuberculosis he gives a good deal of space to experiences tending to confirm the importance of food in relation to the spread of this disease, discussing at some length vaccination, and especially bovo-vaccination. Sleeping-sickness is of only general interest to Americans. Burnett reviews the geography and the history of the disease at considerable length and then discusses the possibility of medicinal cure. His discussion of enteritis is given over almost entirely to what we in this country term mucous colitis, and the fermentations taking place in the intestinal tract in relation to senility. He advocates the use of various methods of preventing intestinal putrefaction as a means of attaining old age. A large part of his article on variola is given over to a discussion of the history of the subject, and in this he has much to say of the personality of Jenner and the men of his time.

MALE DISEASES IN GENERAL PRACTICE. An Introduction to Andrology. By Edred M. Corner, M.A., Surgeon to Children's Hospital. Cloth. Pp. 462, with illustrations. Price, $6. London: Oxford University Press, 1910.

As its name indicates, this work considers the surgical diseases of the organs peculiar to the male. There are a few points which require special approval as they are unusually well presented, though much of the technic developed by American surgeons is not introduced at all and weakened by its absence an otherwise strong work. The chapter on Varicocele is good and a commendable tabulation of the ultimate results of the operation is given showing 70 per cent. of the patients as distinctly improved. Circumcision in old men is advised as a prophylactic for penile carcinoma; also nerve blocking anesthesia is recommended for the operation. A chapter on Hermaphroditism brings out several interesting case histories. Some very pleasing work on the cremasteric reflex is mentioned and certainly opens up a field for investigation. The minor operation of meatorrhaphy is recommended in preference to meatotomy. This places epithelium to mucous membrane and thus avoids the granulation tissues produced in meatotomy. Syphilis is considered only in its initial stage and a strong point is made of the variability of the gross appearance of the chancre depending on its location. In the chapter on sterility the operation of vasoepididymostomy is only mentioned as possible. In discussing vesiculitis, no mention is made of treatment through the vas deferens. In discussing tapping for hydrocele, Belfield's trocar is conspicuous by its absence. A nice point in the use of collodion dressings is illustrated by a neat diagram.

SPONDYLOTHERAPY: Spinal Concussion and the Application of Other Methods to the Spine in the Treatment of Disease. By Albert Abrams, M.D., Consulting Physician to the Mount Zion and French Hospitals, San Francisco. Cloth. Pp. 420, with 100 illustrations. Price, $3.50. San Francisco: The Philopolis Press, 1909.

Opposite the title page appears a list of twelve books by the same author. The *raison d'être* for the book under consideration appears to be that "the subject of spinal therapeutics has received less attention from the medical profession than it deserves. Even the laity knows that cold applied to the back of the neck arrests hemorrhage from the nose, and that heat applied to the small of the back may hasten menstruation. The profound and far-reaching physiologic truths which underly these simple phenomena have either been ignored or *only given inconsiderate attention*."

In looking through this book of over four hundred pages with its 97 illustrations, covering practically every pathologic condition that can possibly have any relation to the spine from muscular hypotonia and vibro-suppression through osteoarthritis, Pott's disease and spondylitis, scoliosis and spinal curvature, sacroiliac disease and sacroiliac relaxation, tumors and typhoid, syphilis, gonorrhea and rickets to pseudoesophagismus and cortical sinusoidalization and many score others, one wonders whether this is an attempt to explain osteopathy and chiropractic to the understanding of the regular practitioner, or to exploit the very ingenious percussion devices of the author, or whether it is really true that medical men really know practically nothing about the cure of disease through treatment of the spine. Let us hope that it is the latter and that a careful study of this unique volume may open new avenues of therapy heretofore undreamed of.

Diagnostic Therapeutics. A Guide for Practitioners in Diagnosis by Aid of Drugs and Methods other than Drug-Giving. By Albert Abrams, A.M., M.D., Consulting Physician to the Mount Zion Hospital and the French Hospital. Cloth. Pp. 1039, with 99 illustrations. Price, $5. New York: Rebman Company [1910].

In this work the author enters what is to a large extent a new field. The attempt is made to show the use of drugs and other remedial measures in determining the diagnosis of disease. Although desirous of limiting himself exclusively to diagnostic pharmacotherapy, it was necessary to add other therapeutic procedures in order to maintain the continuity of the subject. The result of this seems to be a lack of due proportion and emphasis. In the abundance of therapeutic suggestions which flow from the author's reading and experience, it is hard to differentiate those that are of diagnostic value. Some of the statements, we feel sure, have been made without due qualification and without a full appreciation of their real significance; for instance: "Hemorrhages in typhoid fever and phthisis are really due to a plethora, and may be averted, if recurrent, by venesection," page 416. We hope that none of Dr. Abrams' readers will put this method into practice without due discrimination between hemoptysis due to congestion and hemorrhage due to erosion of a blood-vessel.

Ueber den Einfluss der basedow'schen Krankheit und verwandter Zustande auf das Langenwachstum nebst einigen Gesetzen der Ossifikation. Aus der Poliklinik für innere Krankheiten am Serafimerlazarett in Stockholm. Von J. Holmgren, Leitendem Arzt der inneren Abteilung des Provinzialkrankenhauses zu Falun, Schweden. Paper. Pp. 244, with 2 plates. Leipzig: Druck von Metzger & Wittig, 1909.

This monograph gives the results of an investigation of 114 cases of hyperthyroidism in patients under 25 with reference to the height and growth in the length of the body. The author finds that there is an evident association of the disease with increased height, and he concludes that hyperthyroidism favors a rapid increase in the length of the body, and, considering the fact that lack of thyroid secretion, as in cases of myxedema, is accompanied by deficient growth in length, he concludes that it is one of the functions of the thyroid to control the growth of the skeleton. He calls attention also to the relation between a blond complexion and increased height on the one hand and hyperthyroidism on the other. He also brings evidence to show that infections, by action on the thyroid gland, may favor the growth in height. The volume constitutes a valuable contribution to a very interesting subject.

Surgical Anatomy. By John A. C. Macewen, B.Sc. in Anatomy and Physiology with Honors, Fellow of the Faculty of Physicians and Surgeons, Glasgow. Cloth. Pp. 478, with 61 illustrations. Price, $3 net. New York: William Wood & Co., 1910.

This is a discussion of surgical anatomy, such as the physician who operates occasionally stands in need of most. The only departure from the usual work of this kind is that the author surveys the anatomy of hernia from the abdominal instead of from the external surface, which really makes very clear a subject the student usually finds rather difficult to comprehend. Naturally there can be little to criticize in a work of this kind, which is based on established facts. The illustrations, while not numerous, are well chosen and a number of them, especially in the chapter on the head, are new and helpful. The dull-finish paper and the clear, clean type are features worthy [illegible] mention. Section 1 considers the head and neck, vertebral column, brain and spinal cord; Section 2, the thorax; Section 3, the abdomen and pelvis; Section 4, the lower extremity; and Section 5, the upper extremity.

A Quiz Book of Nursing for Teachers and Students. By Amy E. Pope, Superintendent Insular School of Nursing, San Juan, Porto Rico, and Thirza A. Pope, Supervisor of Visiting Nurses of the New York A. I. C. P. With Chapters on Visiting Nursing, by Margaret A. Bewlwy, R.N., Instructor in Visiting and District Nursing in the Presbyterian Hospital, New York. Hospital Planning, Construction and Equipment, by Bertrand E. Taylor, A.A.I.A., and Hospital Bookkeeping and Statistics, by Frederic B. Morlok, Chief Clerk in Presbyterian Hospital, New York. Cloth. Pp. 469. Price, $1.75. New York: G. P. Putnam's Sons, 1909.

This book, while nominally intended for teachers and students, will prove of most value to teachers, 364 of the 461 pages of text being devoted to questions and answers. The remainder takes up visiting nursing, including tuberculosis work, hospital planning and construction, and hospital bookkeeping and statistics. The book should be valuable to superintendents of hospitals, especially those who must combine with the duties of superintendent the work of matron and housekeeper.

A Practical Guide to the Administration of Anesthetics. By R. J. Probyn-Williams, M.D., Senior Anesthetist and Instructor in Anesthetics at the London Hospital. Cloth. Pp. 228, with 44 illustrations. Price, $1.60. Second Edition. New York: Longmans, Green & Co., 1909.

Handbooks and guides to the proper administration of anesthetics appear to be gaining in favor, if we are to judge by the many books on the subject now in the market. Williams' work easily takes position as among the best of these by reason of its excellent arrangement and clearness and conciseness of style. The author has added descriptions of the newer methods and apparatus, and entirely revised the chapter on ethyl chlorid, which he regards in its proper light as a substitute for nitrous oxid and not as a rival of ether or chloroform—and added a chapter on spinal anesthesia. He would reserve the use of spinal anesthesia for those operations below the umbilicus in which a general anesthetic is dangerous to the patient and would never use it in patients who are septic.

Mammalian Anatomy with Special Reference to the Cat. By Alvin Davison, Ph.D., Ex-Fellow of Prince University. Cloth. Pp. 241, with 114 illustrations. Second Edition. Price, $1.50 net. Philadelphia: P. Blakiston's Son & Co., 1910.

This is a brief description of the anatomy of the cat, emphasizing its close relation to that of the other higher mammals. While intended primarily for students of zoology or pre-medical students it will serve as a clear concise guide for any one who has occasion to dissect the cat or one of the ordinary domestic animals. By means of numerous, well-selected illustrations, showing both histologic structure and the gross relationship of the parts, and the clear descriptions, a great deal of information is condensed into a small attractive volume.

Medical Diagnosis. A Manual for Students and Practitioners. By Charles Lyman Greene, M.D., Professor of Medicine and Chief of the Department in the College of Medicine, University of Minnesota. Flexible leather. Pp. 725, with illustrations. Third Edition. Price, $3.50 net. Philadelphia: P. Blakiston's Son & Co., 1910.

The third edition of this book has been largely rewritten and rearranged, includes information on all the new topics, and nothing seems to have failed to receive at least some mention. As stated in our comments on its first appearance, for a brief work on a large subject it is excellent and practical in every way.

Clinical Memoranda for General Practitioners. By Alex. Theodore Brand, M.D., and John Robert Keith, M.D. Cloth. Pp. 207. Price, $1.50 net. New York: William Wood & Co., 1909.

In this brief work the authors have collected memoranda, on a variety of clinical subjects. Much of this matter is not found in the ordinary text-book, but represents the personal experience of the authors. The subjects selected are such as the physician meets daily; cases are related when it is deemed necessary to emphasize diagnostic points, and hints are given as to treatment in various conditions.

Anatomy and Physiology for Nurses. By LeRoy Lewis, M.D., Surgeon to and Lecturer on Anatomy and Physiology for Nurses at the Lewis Hospital, Bay City, Mich. Second Edition. Cloth. Price, $1.75 net. Pp. 344, with 161 illustrations. Philadelphia: W. B. Saunders Co., 1910.

This has been revised and brought up to date by the addition of some new matter, among which are a number of illustrations.

Medicolegal

What Is Privileged Information—Inferences and Testimony as to Necessity—Duty of Physicians Employed by Other Party

The Supreme Court of Utah says, in the personal injury case of Madsen vs. Utah Light and Railway Co. (105 Pac. R. 799), that it seems quite clear that the legislature did not intend that all information, whether by communication or otherwise, which is obtained by physicians from their patients, should be privileged by the Utah statute, which provides: "A physician or surgeon cannot, without the consent of his patient, be examined in a civil action as to any information acquired in attending the patient which was necessary to enable him to prescribe or act for the patient." The statute is not intended as an aid to conceal or smother the truth in a court of justice; but its object is to protect as privileged all that may be said by a patient to his physician while the relation of trust and confidence exists, and, further, to protect all the information a physician obtains through his senses of touch, sight, or otherwise, during such relation, provided the communication or information was reasonably necessary to enable the physician to accomplish the purpose for which the relation of physician and patient is called into existence.

The law does not raise a presumption either way with regard to whether the information acquired by a physician from his patient was necessary for him to prescribe for the patient, but leaves the question as one of fact. Where therefore it is made to appear that a physician prescribed for or treated a person, or that the physician obtained any information from such person for the purpose of doing so, the inference arises that such information was necessary, and, unless this inference is rebutted, the ultimate fact that it was necessary may be assumed to be established. When, however, this inference is negatived by the testimony of the physician disclosing to the court just what the facts were under which the information was obtained, then it may be that the inference is entirely overcome. Quite true, the testimony of the physician may not, in all cases and under all circumstances, be conclusive, and the court may still be justified in holding the information necessary, the statement of the physician to the contrary notwithstanding. If the rule were otherwise, the physician would have it in his power to either enforce the statute with respect to all information, or to ignore it with respect to all. This would be unreasonable.

The testimony of the physician from which the court may determine whether the information was or was not necessary to enable the physician to act is always important, and, the court thinks, should receive fair and full consideration; but in determining its weight and effect it should be considered in the light of all the facts and the surrounding circumstances. In some cases and under some circumstances the statement or information obtained from the patient may be self-explanatory, and thus a mere inspection of it, if written, or merely having it stated, if oral, may be sufficient to enable the court to determine whether the information is privileged or not. In other cases the physician's statement as to whether the information was necessary or not may be conclusive on the subject.

If, in order to enable a physician to prescribe for an injured patient, it becomes necessary for the physician to know how an accident occurred, and he obtains the information while the relation contemplated by the statute exists, the information is privileged, although it may be a narrative of the events leading to an accidental injury. Neither the trial court nor this court therefore should arbitrarily either admit or exclude all information which may relate to the accident or injury; but, in determining whether specific information should be excluded or admitted, the purpose of the statute should be kept in mind, and if, in the judgment of the court, the particular information in question comes within the statute, it should be excluded, and, if otherwise, it should be admitted in evidence.

The plaintiff in this case submitted himself into the hands of two physicians, and permitted them to administer an anesthetic so that they might make a more thorough examination of his person. The physicians made the examination for the purpose of obtaining information to enable them to treat his injury. That they also had another purpose in mind, namely, to learn the scope and effect of the injury for the benefit of the defendant company, in no way changed their relation to the plaintiff.

No doubt the company, through its agents, had a right to obtain from the plaintiff all the information with respect to the cause and extent of the injury he was willing to impart to them; but in obtaining such information it had to exercise some discretion in selecting its agents. If it selected two skilled physicians and surgeons, and thus led the plaintiff to believe or assume that those physicians sought information from him with a view of prescribing for his injuries, then such information was privileged under the statute, regardless of the fact that the physicians sought the information for the further purpose of disclosing it in a court of justice in case he brought an action for damages against the company. If the physicians desired to obtain the information for the latter purpose only, they should have explained the matter fully to him, and should have told him that they sought the information for the purpose of imparting it to the company, and not for the purpose of aiding him.

If, under the latter circumstances, the injured person permits an examination, or imparts information, no confidence is abused, and no statute is invaded, and hence he may not be heard to complain; but persons who are injured by accidents of any kind should be treated fairly by the skilled physicians who seek information of the character protected by the statute. The statute is plain, and its purpose is just and humane. It seems to this court that it is the duty of the courts to give the statute full scope and effect; but, in doing so, to prevent, if possible, either party from gaining an advantage contrary to the true spirit and intent of the statute.

Death Certificate Not Evidence

The Court of Appeals of Kentucky says, in Louisville Railway Co. vs. Raymond's Administrator (123 S. W. R. 281), wherein the administrator sought to recover from the railway company for the death of the said Raymond, alleged to have been the result of an injury caused by the negligence of the company, that the company offered in evidence a copy of the death certificate made by the attending physician, showing the cause of the death as tuberculosis. But this was not permitted to be read in evidence, and the court holds properly so, it not appearing that the physician who made it was himself dead at the time of the trial. If he were dead, a different question would be presented, though what the decision on it would be is not stated. While the Kentucky statute requires the physician to give the death certificate, there is nothing in the statute making the certificate evidence in judicial proceedings, and it stands entirely on a different plane from the return of an officer made pursuant to law under his official oath. The law requires the best evidence, and the best evidence would be the testimony of the physician, if living.

Validity of Cocain Ordinance—City Cannot Impose Forfeiture of Licenses

The Court of Appeals of Maryland holds constitutional, in Rossberg vs. State (74 Atl. R. 581), an ordinance of the city of Baltimore prohibiting the sale, furnishing, giving away, or having in possession cocain and kindred substances, or compounds thereof, except on certain conditions provided in the ordinance, but invalid so much of the penalty as provided that if the offender was a licensed pharmacist, physician, dentist, or veterinary surgeon, he should forfeit his license. The court states that it is not prepared to say that where a pharmacist, physician, dentist, or veterinary surgeon, in violation of the restrictions of the ordinance, deliberately or recklessly sells the prohibited drugs, or keeps them in his possession for the purpose of such sale, that the forfeiture of his license is so oppressive as to be unreasonable. On the contrary, it is disposed to believe that both with regard to the depravity of the offender, adequate penalty. But the trouble here was that the city charter did not give it power to declare any forfeiture, while the general rule is that an ordinance cannot create a forfeiture and to the protection of the public against the evil at which the ordinance is aimed, forfeiture of license is the only fully in the absence of express legislative authority to do it.

2 Tuberculosis and Its Treatment by Administration of Mercury. B. L. Wright, U. S. Navy.
3 *Value and Proper Method of Performance of Auscultatory Percussion of the Heart. W. F. Milroy, Omaha.
4 Plastic Induration of the Corpus Cavernosum. H. J. Whitacre, Cincinnati.
5 *Practical and Potent Means of Reducing Infant Mortality from Diarrheal Disease. J. Sobel and L. Marcus, New York.
6 Congenital Cataract, Successful Operation at the Age of 23 Years. M. Talmey, New York.
7 The X-Ray and Ultra-Violet Ray in Dental Diagnosis and Treatment. S. Tousey, New York.
8 Cerebrospinal Meningitis. C. Bagley, Baltimore.
9 Case Illustrating the Arrest of Early Paresis. T. A. Williams, Washington, D. C.

1. **X-Ray Diagnosis of Tuberculosis.**—As a means of early diagnosis, the fluoroscope, Minor says, while useful, is, save in the case of bronchial gland shadows, by no means equal to an expert use of standard physical diagnostic methods. Many *x*-ray specialists differ from this view, some maintaining that it is a far earlier means of diagnosis, but Minor is satisfied that this is chiefly due to the fact that the radiologist is rarely an expert physical diagnostician. In Germany, where several distinguished diagnosticians have used the *x*-ray freely, extreme assertions for the early diagnostic value of the ray are not so common as in this country. Hence the statement that any given case was negative on physical examination and showed shadows with the *x*-ray is of no great value unless it is known who made the physical examination. Minor has not found that the *x*-ray examination can give information antedating rough inspiration, feeble breathing or slight vesiculobronchial breathing, as it must if it is to precede physical signs, and when the pathologic conditions which produce these slight changes are considered, it seems most improbable that they should cause shadows.

3. **Auscultatory Percussion of the Heart.**—The method of performing auscultatory percussion of the heart, recommended by Milroy can easily be performed with the patient in the upright position. It is more conveniently done with the patient in the dorsal position and the examiner at his right side. The objective end of the stethoscope is placed immediately to the left of the sternum and extending upward from the fourth space. The instrument is held in this position with moderate pressure by an assistant or by the right hand of the patient. A finger of the examiner's left hand serves as the pleximeter. Milroy prefers the little finger, as thus one's hand does not interfere with the stethoscope. It is placed in the fifth intercostal space at a point so far to the left as to be entirely beyond the cardiac border. The pressure of the pleximeter finger must be uniform, as it is moved from place to place during the performance of percussion. To secure this uniformity it is advisable that the pressure of this finger be so firm that the fifth and sixth ribs are both distinctly felt in each position of the finger. The percussion stroke must be of very moderate intensity and must be uniform in force. Thus inaugurated, percussion is made from left to right until the pitch of the percussion note is observed to change, the site of this change representing the situation of the left border of the heart. In determining the situation of the right border the procedure is similar. The chest piece of the instrument is placed at the left of the sternum over the heart. Percussion is made in the fourth space, at which level is found the greatest projection of the heart to the right. Commencing well beyond the cardiac limit the examiner passes from right to left, noting the border of the heart at the point where the change in the quality of sound first appears. Similar percussion will locate the right border at other points, if so desired.

5. **Lectures and Infant Mortality.**—During the summer of 1908 and 1909, the Department of Health in New York City appointed six physicians to act in the capacity of lecturers to the mothers and *"little mothers;"* these lectures, or rather short heart to heart talks, were given for the greater part during the afternoons in the public school recreation centers, and occasionally at night, on the roofs of other institutions. The subject matter was summer care of babies, all that prophylaxis and treatment of the children entails. With this lecture, the authors feel that they have accomplished more actual good, gained more positive results, prevented more gastrointestinal disease and terminated more cases in their incipiency during the last two summers than during all the previous summers under other systems. The future problem of reducing infant mortality from summer diarrhea lies in the procuring of clean, cool milk. If the laity could be educated to the fact that the intelligent use of milk of the aforementioned type will prevent diarrhea a great advance will have been made. This system is only in its developmental stage and great possibilities are in store for it. With each succeeding year the daily attendance will increase so that in time a large proportion will receive instruction in this way. Already the tenement house population in New York has been aroused and interested by the dissemination of knowledge obtained at these lectures. The use of grocery milk for the feeding of infants has been markedly diminished. The vicious habits of feeding with any and all kinds of gastroenteric irritants was curtailed. The obnoxious habit of adding large quantities of brandy to boiled and cereal waters and the giving of beer and wine to older children has been in a great measure remedied.

13 The Value of Continuous Intratracheal Insufflation of Air (Meltzer) in Thoracic Surgery. C. A. Elsberg, New York.
14 Curious Arrangement of Capsule of the Lens After Simple Extraction of Cataract. J. S. Fernandez, Havana, Cuba.
15 Lumbar Analgesia. M. Breuer, Buffalo, N. Y.

11. **Apparatus for Thoracic Surgery.**—Meyer criticizes in detail the various apparatus used in thoracic surgery and formulates the following conclusions:

1. Intrathoracic surgery cannot be done properly and safely without differential pressure apparatus.

2. Negative and positive differential pressure are, it seems, not identical in their effects on sick human beings. Whether they are or not, must still be established, and indications be found for their use. This is rendered feasible by the universal differential pressure chamber.

3. Continuous intratracheal insufflation as practiced by Meltzer and Auer appears to be a positive differential pressure system.

4. Its weak points are the use of the human trachea as a vital part of the apparatus; the possibility of aspiration at the beginning of the operation, with subsequent pneumonia, and of interstitial emphysema at the end of the operation, as a consequence of its employment; also the required deep anesthesia. Intubation reaching below the glottis has been found to give rise in the human trachea to immediate copious secretion of mucus.

5. Sudden complete interruption of the prevailing differential pressure, followed immediately by its equally sudden restoration, as practiced in continuous intratracheal insufflation, is liable to hurt the human heart. Very slight changes in intrabronchial pressure give rise to very great changes in blood pressure.

6. Continuous intratracheal insufflation apparatus is not adapted for use in the after-treatment, nor is it otherwise all-sufficient. Those employing it need some other type of differential pressure apparatus in addition to it, in order to be prepared for every emergency.

7. The safest method of general anesthesia is the one used in our every-day surgical work, the inhaling of the narcotic with spontaneous respiration and with mouth and throat left unencumbered. This method is the one used in the larger differential pressure chambers.

8. In surgery, when entrusting human life to the safe working of mechanical apparatus, it is wise to have substitutes on hand, in order to be prepared for accidents. In continuous intratracheal insufflation everything depends, at present, on the one cannula and the patency of the trachea.

9. So far as the patient is concerned, a differential pressure system leaving mouth, throat and trachea unencumbered, appears preferable to one requiring intubation.

17. Restraint Instead of Treatment in Hospitals for the Insane.—It is evident to any one who has intelligently studied the conditions of the insane, that there is very little treatment and decidedly too much restraint. Fifty years ago it was not expected that insane persons would have much more than board and restraint. If they did not hurt themselves or other people, the public seemed to be satisfied. The same conditions exist as to a greater part of our insane to-day. It seems that legislation is sadly needed to abolish restraint, excepting as a life-saving measure, but if this is impossible, then to regulate the amount of restraint used, the conditions under which it shall be used, and that each individual case shall have the same amount of medical care and supervision as in any other disease. More physicians should be assigned to the care of the insane in institutions; women nurses should, to a greater extent, replace male attendants. If the barbarous custom of restraint must be continued, all appliances should be kept in the office and under the lock and key of the superintendent, who should see every patient and decide whether or not restraint is necessary, and should make a record of the kind and amount and different forms of restraint used. This should apply not only to state institutions for the insane, but to general and private hospitals.

48. Education of the Insane.—The so-called chronic insane are subdivided by Robinson into three classes—the progressively incurable dements, such as the paretics and senile dements; the physically helpless, such as the paralyzed and those who are neither physically helpless nor afflicted with progressively incurable dementia. Patients in the two former classes constitute a small percentage of the hospital population, and about all they need is kind treatment, good nursing and careful attention to their physical needs. This they get in most, if not all state hospitals. The greater percentage of the population in state hospitals is composed of a class of persons who have entered the hospital as acute patients, who have not been restored to health, and who are left over, as it were, from year to year, until there is a large accumulation. These people are not sick, but are in good physical condition. They do not need hospital treatment, excepting occasionally as one of them has an acute attack of sickness of some character. For them the insane hospitals are nothing more than jails, the only function of which is custodial; the insane person must live alone with his delusions and a mind concentrated on the ego. It is not surprising that these patients frequently become violent and have to be restrained by mechanical means and sedative drugs. What they need and want is mental and physical occupation. They must be given occupation for all the faculties of the mind and work for the hands. Some of them show very little mental reduction and likewise very little perversion of mental faculties. Those who show the greatest amount of mental reduction should be treated as very small children who are beginning on the first principles of education. They should be given a kindergarten course just as the small child, with about the same course of study. Those who have suffered less mental reduction need not begin with the fundamentals, but they can begin a little farther on in the course which should be progressive in character and should be systematically carried out. In addition to the kindergarten department there should also be a well-equipped manual training department. These departments should be directed by well-qualified teachers. Every insane hospital should have a well-furnished general library for the patients' use. These patients should be encouraged to read wisely selected books and brought together at certain intervals by a competent teacher to tell what they have been reading. They should also under the direction of a well-qualified teacher be given a course of ordinary school study.

The most important part of the treatment, however, is the manual training department and ordinary labor. A course in a well-equipped and well-directed manual training department is, perhaps, the best method of producing all-around mental and physical development. Every faculty of the mind as well as the hands are exercised and developed. An industrial building for the industrial reeducation of these patients is very essential. In such a building the clothing of all the patients can be made, mattresses manufactured, furniture repaired, and much new furniture made, etc. Such a building will pay in money saved the institutions which is now spent for such supplies as can be made by the patients. Many of the women patients are now employed in all hospitals in the wards, laundry, kitchen, dining-rooms, etc., while many of the men are employed on the farm, in the dairy, in repair work on buildings, cleaning the campus, building fences, working in concrete, road building and, in short, doing about everything and every kind of work there is to do.

66. **Decompression in Meningitis.**—Hultgen reports four cases. The first case was one of serous meningitis, cured by lumbar puncture alone. The patient is now in excellent health. The second case was one of undetermined meningitis, but probably of influenzal nature (leucocytic formula, pneumonia, and otitis media). Improvement occurred after lumbar puncture and progressed to complete recovery. The patient is in good health now. The third case was one of acute meningitis, probably influenzal, with very rapid recovery after decompression. The patient is in good health now. The fourth case was one of tuberculous meningitis, with recovery. Lumbar puncture, as the only therapeutic measure used in this case, must be considered curative. The removal of intracranial hyperpressure, that is, decompression, was accomplished promptly and thoroughly by means of two consecutive lumbar punctures.

70. **Hemophilia.**—The points of interest in connection with Larned's case are: (1) the inheritance came through the father, who was himself a bleeder; (2) this is the first case, so far as Larned knows, of typhoid fever reported in a bleeder; (3) a case of typhoid may be brought to a successful termination in a patient so afflicted; (4) no hemorrhages occurred from the intestinal lesions; (5) the successful termination in this instance was probably in large measure due to the fact that at or about the age of forty the hemorrhagic tendency abated; (6) in this man's case the principal manifestation of the hemorrhagic tendency had been attacks of epistaxis, the only other serious hemorrhage having occurred at the time of an operation for ingrowing toenail.

71. **Compressed-Air Illness.**—McWhorter endeavors to prove the following:

1. In subaqueous tunnels the loss of air by leakage is sufficient to maintain perfect ventilation, and, therefore, carbon dioxid, carbon monoxid, and other gases do not accumulate in sufficient quantities to be considered possible etiologic factors in the causation of compressed-air illness.
2. The direct cause of compressed-air illness is the presence of air bubbles in the circulation; these gas bubbles consist of nitrogen, carbon dioxid, and oxygen, of which nitrogen is in excess, for the reason that this gas is the chief constituent of the atmosphere, and also does not combine with any of the body tissues.
3. New workers are most susceptible to this disease until the body accommodates itself to this entirely abnormal condition of high air pressure; and therefore, it is of the utmost importance that only young, healthy men should be allowed to do this work. New workers should, when feasible, be started in low pressures, from which in the course of four or five days, they may graduate to become, as they are called, "high-pressure men."

72. **Myomata Congenita.**—Haberman reports three cases which presented certain points in common—a rather extensive apparently flaccid paralysis, with absence of patellar and Achilles reflexes. In one there is vasomotor disturbance, in another slight atrophy, masked however, by adiposis. Viewed thus far, these cases might be taken for anteropoliomyelitis. A little closer analysis, however, will bring out certain interesting facts—namely, that two cases with certainty, and one case quite probably, date from birth, or, in other words, are congenital. Congenital cases of anteropoliomyelitis appear not to exist. Haberman believes that the one case cited in the literature has nothing to do with poliomyelitis, as two other children of the family were similarly afflicted (familial intrauterine poliomyelitis), and the paralysis was progressive—increased instead of decreasing, as is the rule in anteropoliomyelitis. Furthermore, there is no really degenerative atrophy present with reactions of degeneration. The paralysis, which is extensive, especially in two of Haberman's cases, has not gradually confined itself to an area smaller in extent than that which was at first affected, as is almost invariably the case in anteropoliomyelitis. Finally, on careful examination, one sees that some movements are present in the affected muscles, that we are not really dealing with genuine paralysis, but with an extreme condition of muscular atony. These muscles feel soft and doughy, and, except in one case, are not cold to the touch.

The clinical picture of myatonia congenita is a typical one, and may be described, Haberman asserts, as a congenital, atonic pseudoparalysis, encountered in the first two or three years of childhood, when the reflexes are very weak or abolished, electrical reaction reduced but never degenerative, real atrophy not met with, the distribution proximal with no progression, the muscles or bulbar innervation practically exempt, and no sensory, bladder, nor rectal involvement occurring. In a minimal group the children are older, contractures are present, the muscles small and thin (atrophic?).

75. **Acute Pulmonary Edema.**—The observations made by Ohlmacher in 5 cases, should, he says, tend in two directions—to emphasize the importance of acute edema of the lungs as a concurrence in epilepsy, and further to illustrate the kinship between certain types of epilepsy and status lymphaticus.

103 *Reinforced Plaster Splint. R. M. Thornburgh, U. S. Army.

103. **Reinforced Plaster Splint.**—The idea of this splint was suggested to Thornburgh by reinforced concrete building construction. After reduction of the fracture in the usual way, the leg is encased in one thickness of absorbent cotton and this is held in place by a few turns of roller bandage, applied tightly. A wet plaster roller is now wound round until at least two thicknesses surround the leg. A sufficient length of

wire mesh is placed along the inner side of the leg and bent over the sole of the foot to form a stirrup. By cutting a few wires here and there it can be perfectly moulded to the plaster dressing already in place. The outer side of the leg receives a similar strip of mesh but no stirrup. The strips of mesh should leave a gap of about an inch both in front and rear. While assistants hold the mesh in place the operator again applies the plaster roller until several layers are outside of the mesh. Plaster is applied by hand in the usual way, but only half as much is used as in the ordinary plaster splint. The dressing is allowed to set for several hours and then split with saw or cutting pliers down front, back, and along top of stirrup. Two perfectly formed moulds are thus made, which are held in place by adhesive straps or tapes embedded in the plaster. These straps may be tightened as the limb becomes emaciated or the pressure may be exactly regulated, for the splints will neither bend nor break. The patient can move about in bed, without danger of disturbing the relations of the fragments.

119 *Influence of Dietary Alterations on the Types of Intestinal Flora. C. A. Herter and A. I. Kendall, New York.

116. **Purin Metabolism of the Monkey.**—Wells finds that the monkey like other mammals possesses the power of destroying uric acid by an oxidase found in the liver. The urine of monekys contains very little purin nitrogen. A small amount of uric acid was found in the urine of a monkey dying from tuberculosis, but was not present in the urine of normal monkeys.

117. **Effect of Castration on Metabolism.**—McCrudden reaches a result somewhat at variance with the common idea that castration tends to produce obesity. There was no retention of material, especially of the mineral elements, but the results show a general tendency in the opposite direction; when there was a retention of material before castration, this retention was either decreased or became a loss after castration in almost every instance. Clinical investigation does not sustain the view that obesity is likely to follow the removal of the ovaries in women as a rule. The experiments of McCrudden appear to bear against the theory that osteomalacia is a disease of the ovaries which is cured by castration. This theory McCrudden proposes to discuss in a subsequent paper.

119. **Dietary Alternations and Intestinal Flora.**—The authors' experiments on kittens and monkeys show that an abrupt change in diet from a dominantly protein (meat and eggs) to a milk and sugar diet is followed by an alteration of physiologic conditions in three distinct directions (a) in the nature of the intestinal flora; (b) in the putrefactive products of the feces and urine; and (c) in the clinical conditions. The chief characteristic of the bacterial change is the gradual but rapid substitution of an acidophilic non-proteolyzing type of flora for a strongly proteolyzing type. The chief feature of the putrefactive conditions in the intestine is the reduction of the indol, skatol, phenol and bound hydrogen sulphid and a diminution in the indican and aromatic oxy-acids of the urine. Clinically, the most striking feature of the change in diet is (in monkeys) an improvement in spirits and activity which may safely be construed as showing a markedly improved sense of bodily and physical well being. While some of these changes may be due to reduction of protein it seems much more probable that the changes in the flora observed are mainly due to the influence of the carbohydrates and that the diminished intestinal putrefaction is due to the combined influence of diminution in protein and the addition of carbohydrate materials to the diet. The physiologic alternations in the flora which the authors claim to have established by their studies have been noted only in normal animals. They have as yet made no effort to study the effects of diet on animals in which the digestive tract is the seat of inflammation. They consider it likely that analogous conditions will be found to exist in man.

129 *Simultaneous Case of Intrauterine and Extrauterine Pregnancy. S. C. Rumford, Wilmington.
130 Dr. Jos H. Chandler. J. P. Pyle, Wilmington.
131 Id. H. W. Briggs, Wilmington.

129. **Intrauterine and Extrauterine Pregnancy.**—The patient last menstruated in July, 1908. April 13, 1909, she had poor labor pains, which gradually ceased after a few hours; the same thing occurred on April 17 and 24, but on none of these dates was there any dilatation of the cervix. April 26, a bloody product was passed after unusually severe pains, and proved to be a six weeks' fetus and placenta. At this time the cervix was soft and dilated and fresh blood coming from the uterine cavity. The patient was very comfortable for several days, but there was no decrease in the size of her abdomen and she still felt fetal movements. She was taken to the Delaware Hospital, Wilmington, May 3. Examination showed the abdomen distended with fluid. In the left flank a mass could at times be detected that seemed to float away from the examining hand. It was impossible to outline this mass by the vagina or to locate the fundus because of the intra-abdominal fluid, but the cervix was soft and patulous and a pale lochial discharge was present. As the patient was in poor condition and much exhausted by her trip to the hospital, a couple of days were spent in getting her in good shape for operation. On opening the abdomen by a median incision, Rumford found the cavity filled with a dark brownish and very offensive fluid, and floating about in this a male child at full term, showing very feeble signs of life. The intestines had been forced up under the lower border of the ribs, and confined there by an unusually large but thin placenta, which was adherent to the intestines, omentum, liver and the parietal peritoneum along the right side of the abdomen. The whole peritoneal cavity presented a pale, unhealthy appearance, and in separating the placental adhesions there was little tendency to bleeding. The uterus was enlarged and soft, and the tubes and ovaries normal. The child had the same pale, macerated appearance as the other structures and in delivering it the cord was broken, but from neither end was

there any bleeding. The child, after a couple of gasps, ceased breathing and its heart refused to beat in about ten minutes.

139. **Resection of Posterior Spinal Roots for Relief of Spasticity.**—This operation was first advocated by Spiller early in 1905. He stated that it was permissible in almost every case in which spasticity is great and motor weakness is slight, provided the condition of the patient justified it, whether the lesion be spinal or cerebral, unilateral or bilateral. It is useless when motor palsy is great. Frazier performed this operation with much success in one case, which Spiller and Frazier report. The man's trouble began in December, 1903, following a drinking bout. He was examined by Spiller, Sept. 25, 1909, in view of operation. The notes of this examination are as follows: Voluntary power in lower limbs is about normal, but spasticity in these limbs is extreme. He cannot separate the thighs because of this great spasticity. The patellar tendon reflex is so exaggerated on each side that a tap on the patellar tendon throws the corresponding limb into a general clonus. Patellar clonus, so-called spinal epilepsy, persistent ankle clonus, and Babinski reflex are present on each side. Touch, pain and temperature sensations are normal in each lower limb. The cremasteric reflex is prompt on each side. The sense of position is normal in each great toe. He has control over the bladder and rectum. He is unable to walk without support (canes) because of the extreme spasticity; the toes of one foot catch behind the heel of the other foot in walking, and when he is standing still the heels do not touch the ground because of the spasticity of the calf muscles. Spiller examined the patient again on Sept. 28, 1909, after the operation. The notes of this examination are as follows: He has touch, pain and temperature sensations in the legs below the knees and in the back of the thighs, but has no touch and temperature sensations on front of either thigh. On the front of the left thigh, he feels pin pricks, but cannot feel them on the front of the right thigh. The patellar reflex is completely lost on each side; Achilles reflex is nearly normal on the left side, but is weak on the right side. He lies with thighs far apart and legs extended. He feels touch, pain and temperature sensations in front of the abdomen. He complains of much pain low in the back, and pain is intense here on voluntary or passive movements of lower limbs. The cremaster reflex is lost on each side. He can flex slightly each lower limb at the hip, knee and ankle, and moves his toes freely. He moved his right lower limb freely, he says, a couple of hours after the operation, the left not so well. Both lower limbs and lower abdomen as far as the umbilicus feel as though dead. In October, 1909, he was able to stand if supported, but could not put much weight on the lower limbs. Pain was not so severe now as it was soon after the operation. The movements of the lower limbs were free, and he had control of the bladder and rectum. On December 17 there was great impairment if not complete loss of sensations for touch, pain, heat and cold in an area very nearly similar on the two sides and confined to the front and sides of the thighs. He can separate his thighs, flex and extend them to the normal degree. The patellar reflex is present on the left side in so far as there is distinct contraction of the quadriceps muscle, but there is no movement of the left on the thigh in this reflex. The patellar reflex on the right side is present but very weak. The Achilles reflex is nearly normal on the left side, but is very weak on the right side. Typical Babinski reflex is obtained on each side. He gets in and out of bed without difficulty. He moves his feet at the ankles with much freedom, but not to the normal degree, and places his feet firmly on the ground. There is no positive disturbance of sensation below the knees. The functions of bladder and bowels are normal. He goes up stairs with freedom, but has difficulty in descending stairs. He walks with a cane and a crutch. He has still some tendency to drag the toes, but in nothing like the degree that was present before the operation. The movements at hips and knees are nearly normal, but are still impaired at the ankles.

141. **Splenomedullary Leucemia in Childhood.**—Karsner adds one case to seven now recorded in the literature. His patient was 2 years old.

143. **Extrasystolic Arrhythmia Simulating Heart-Block.**—An interesting case of myocarditis is reported by Norris. That it was a case of myocarditis was evidenced by the physical examination by a marked limitation in the field of cardiac response, and by the pulse tracings, which showed at times a marked delay of conductivity and also a typical pulsus alternans, both of which conditions are of bad prognostic import. The patient was suffering from a very atypical form of arrhythmia, which was clinically manifested by a disappearance of every other arterial pulse wave, thus suddenly and often for a considerable interval of time halving the pulse rate. For a period of about three weeks this arrhythmia could be brought on at will by deep breathing and other simple procedures and was apparently always associated with, and at least in part the result of, increased blood pressure. It was positively not a case of auriculoventricular heart-block. The administration of digitalis invariably made the condition worse and sometimes seemed to be the direct cause of it. The effect of belladonna, on the other hand, seemed to be beneficial, and considering the diametrically opposite effect of these two drugs on the vagus, suggests that this nerve may have played an important part in the production of the arrhythmia. Certain reasons may be advanced for believing that we were not dealing with extrasystolic arrhythmia properly understood at all, but with the condition which has been designated as "true bigeminus;" the close-coupled contraction of left ventricle as well as the auscultatory examination of the heart, would, however, seem to contradict this belief. Norris believes that the form of the arrhythmia varied at different times and that sometimes it was not a "true bigeminus," at others there were undoubted extrasystoles. One other explanation, however, seems possible, *i. e.*, that the peripheral pulse intermissions simply resulted from an extreme degree of myocardial weakness, which caused the small waves of a pulsus alternans to drop out entirely. The author states that he has never seen such a case described, but can see no reason why such a state of affairs should not be perfectly possible. Three other cases are reported. Basing his conclusions on these four cases, Norris states that extrasystolic arrhythmia may simulate heart-block by the fact: (1) that the peripheral pulse may be very slow; (2) that the jugular veins may be distended and pulsate markedly in the intervals between the radial pulses; (3) that a muffled third muscular sound may be heard on auscultation over the heart which does not correspond to a peripheral pulse; (4) that there are no distinctive symptoms of true heart-block.

144. **Anatomy of Epicranial Aponeuroses and Temporal Fascias.**—Davis finds that effusions beneath the epicranial aponeurosis are limited below as follows: The occipital protuberance, superior curved line of the occiput, mastoid process, top of the ear, upper edge of the zygoma, external angular process and possibly, for a short time, at the upper edge of the orbit, but either at once or in a comparatively short time invade

first the upper and then the lower lids. The outer side of the orbit seems to be an especially favorable spot for effusions to gain entrance to the subcutaneous tissues of the lids. The accumulations occurring above the zygoma may either remain above it or possibly, especially if serous, leak through and extend a short distance below. Effusions occurring beneath the pericranium of the parietal region may, as pointed out by Richet, descend toward the temporal region, in which case they pass over the deep temporal aponeurosis.

145. **Karyokinetic Leucocytes in Leucemia.**—Pepper found that there is no more resemblance between the karyokinetic cells in acute lymphatic leucemia and in splenomyelogenous leucemia than there is between the typical "large lymphocytes" and the myelocytes of the same disease.

165. **Prophylaxis of Social Evil.**—As it has been demonstrated that the treatment of the venereal diseases is the best prophylaxis against the spreading of the scourge, it is clear that some interstate rules concerning this treatment would be of great advantage to combat their diffusion. These rules, according to Ravogli, could be formulated as follows:

Every hospital (unless it be for special diseases) is compelled to accept venereal patients when disabled. In every general hospital there must be a department for the treatment of venereal diseases. In these wards there must be observed complete secrecy and discretion, in order to prevent any publicity. It must be in the power of the health officer to compel any hospital to give treatment to a disabled venereal patient. In large cities the patients must have the benefit of the clinics and dispensaries attached to the hospitals or to the medical colleges. In smaller communities dispensaries must be instituted for treatment of venereal diseases, by order of the county board of health. Medicines and treatment for poor patients must be given free of charge. Physicians in charge of these dispensaries must be specialists well-trained in the treatment of these diseases.

2. **Streptotrichoses and Tuberculosis.**—In the course of an investigation of 53 cases of streptotrichoses in man, Foulerton found 6 distinct species of parasites. In one case it was easy to identify the streptothrix described by Eppinger; and from other cases he isolated 5 distinct species which he has not been able to identify positively with previously described parasites. The influence of occupation and other circumstances involving special exposure to the possibility of infection from a vegetable source is noticeable in this series. Of 27 persons belonging to the working classes, 19 followed trades in which they would be specially exposed to any infection which might have its source of origin in vegetable matter. Thus there were among them 5 men employed in stable work; of these, 1 had a primary pulmonary streptotrichosis and died with a secondary abscess in the cerebrum, another had a streptotrichial empyema secondary to a lung infection, 2 had abscess in the submaxillary region, and 1 had an abscess in the substance of the cheek. A patient with a streptotrichial appendicitis was a cellarman who was constantly handling the straw casings of wine bottles, and who happened also to live over some stables. Two of the patients were bakers, one with a subperiosteal abscess of the lower jaw, and one with a right iliac abscess which presumably was secondary to appendicitis. Two of the patients were gardeners, both with abscesses of the submaxillary region. Two other patients whose occupation would expose them to the risk of infection of this kind were a dairy maid, who suffered from a submaxillary abscess, and

a man with a streptotrichial appendicitis who had been employed for many years in a large timber yard.

Among these 19 workers, who by reason of their occupation might be supposed to be specially liable to infection of this kind, there was a group of 7, including 2 working tailors, 3 tailoresses and 2 dressmakers, who would be in the habit of passing cotton and thread between their lips. Of these the 2 tailors each had a submaxillary abscess; the 3 tailoresses suffered respectively from a pulmonary streptotrichosis, an acute parotid abscess, and a submaxillary abscess; one dressmaker died with thrombosis of the superior mesenteric, splenic and portal veins resulting from a streptotrichial appendicitis, and the other had a submaxillary abscess. The remaining 8 of the working classes followed as many different trades, in none of which could any probable cause of any special liability to exposure to infection be traced. In 2 other cases, one that of a woman medical student who died with extensive retroperitoneal suppuration following on a streptotrichial appendicitis, the second that of a young male of no special occupation who died with infection of the lungs, liver and cerebrum—there were circumstances of interest in connection with the probable source of infection. The woman had spent a long holiday in the country ending 3 months before the onset of symptoms of appendicitis, and while away had been in the frequent habit of chewing ears of growing barley and oats as she walked through the fields. The male patient died within 4 months of leaving a farm on which he had spent several weeks during convalescence after scarlet fever.

4. **Treatment of Tuberculous Abscesses.**—The combined mixture which Calve and Gauvain use for injection into cavities after aspiration is of this formula: Iodoform, 5 grams; ether, 10 grams; guaiacol and creosote, 2 grams of each; and sterilized olive oil, 100 c.c. Of the other solutions of iodoform, iodoform combined with ether is most commonly used. Out of 29 cases of spinal caries with abscesses, 27 were cured, 2 remain with sinuses which are not infected and in which the discharge is diminishing and the general condition is good. There were 33 cases of hip disease; of these, 32 patients were cured, 1 remained with a sinus. In this case, the sinus was serious, due to a secondary infection caused by improper sterilization of the instruments employed in aspiration. The number of aspirations was from 1 to 21 in each case. At the Cripples' Home at Alton, during the last months of 1909, 23 closed tuberculous abscesses connected with lesions in the spine, hip and knee have been treated by aspiration; 8 spinal abscesses were aspirated. The greatest number of aspirations required for any one case was 12, the average number required was 3. All the patients are apparently cured, and in no case has a sinus formed. Thirteen cases of abscess in connection with tuberculous disease of the hip were treated by aspiration. Of these 12 patients had been apparently cured. In one case, a small sinus persists, but is not infected. The greatest number of aspirations required for any one case was 14. The average number was 4. Two abscesses in connection with the knee-joint have been similarly treated, and both patients are apparently cured.

5. **Phthisis and Menstruation.**—The changes associated with pulmonary tuberculosis were found by Welch to be progressively more marked in proportion to the severity and extent of the disease. Thus in early cases the changes most frequently found are a depression in the temperature, somewhat more marked but otherwise similar to that occurring in the healthy woman, except that the temperature falls on the first day and not on the day preceding the flow; and, further, the progressive and preliminary rise in the intermenstrual period appears to occur but rarely, being present in only three of his cases. In patients with two lobes affected a definite rise occurs in more than half of them while in women with three or more lobes affected a simple depression occurs in only 14.2 per cent., a rise of 57 per cent. Welch was unable to trace any definite variation of pulse rate and respiration with these changes of temperature. In like manner the amenorrhea that is so well-recognized as a sequel of this disease is found to increase progressively in proportion to the extent and severity of the disease. In early cases it occurred in 11.9 per cent., in the two-lobed in 23.7 per cent., while in the severe and advanced it occurred in as many as 62.5 per cent.

6. **Proctopexy.**—The operation devised by Mummery so anchors the rectum as to render impossible any possibility of the posterior rectal wall prolapsing. A transverse incision about 2 inches long is made about half way between the tip of the coccyx and the posterior margin of the anus. This incision should divide the attachment of the external sphincter to the coccyx and should be carried down until the posterior rectal space is opened. With the gloved finger this space is freely opened up. The height to which the posterior rectal space should be separated depends on the length of the prolapse, but in any case it should be well up into the hollow of the sacrum. The end of the gauze is left protruding from the wound which must be left open. A lot of gauze must not be pushed in, but only just sufficient to prevent the rectum and the tissues on the front of the sacrum from healing together by primary union. The external wound is carefully dressed, a piece of gauze being placed in the anus to prevent the dressings from becoming soiled. Mummery has performed this operation four times with complete success. In each case about five inches of the bowel came down previous to operation. The advantages claimed for this operation are: (1) It securely and permanently fixes the whole posterior rectal wall into the hollow of the sacrum; (2) it is simple and does not involve any serious risk; (3) it does not involve the cutting of any nerves or important structures; and (4) it restores the bowel to as near the normal condition as is possible.

14 A Trial of Nastin. J. A. Thompson.
15 *Peritoneal Blood Transfusion. A. E. Boycott.

8. **Optic Neuritis or Papilledema.**—Horsley holds that the maximal intensity and age of papilledema or optic neuritis in cases of increased intracranial tension is of the highest value in clinical localization of the lesion, and is ipsolateral with the maximal pressure effects of the latter. Papilledema produced by increased intracranial tension commences at the upper border of the optic papilla, and invades last the inferior temporal quadrant. Horsley agrees with Mr. Gunn that the macular figure is caused by tension lines centered at the fovea, the greatest stress being just beneath the intima. The phagocytes of the retina, he says, consist of several kinds, as follows: (1) Wander-cells; (2) connective tissue corpuscles; (3) epithelioid corpuscles of the nerve fiber layer; (4) epithelioid corpuscles of the outer granule layer—the two latter varieties being in close relation to the supporting fibers of Müller.

9. **Miner's Nystagmus.**—Butler agrees with Reid and Nuel that the disease is caused by a disordered cerebration, a defect in the brain, not of the eye muscles. It is produced by the peculiar work of the miner, long-continued rhythmic movements of the pick in comparative darkness. The treatment is simple. The miner must leave the mine, and must not return to it. The prognosis must be guarded. Many patients recover completely, but, on the other hand, some never entirely lose their symptoms. In any case, a miner who has once suffered from the disease must never return to work underground.

10. **Muscular Dystrophy in an Adult.**—A "plater" in a shipbuilding yard, aged 28, had been accustomed to severe muscular exertion, particularly of the arms and back. He was a total abstainer, and had had no serious previous illnesses, except a suppurating inguinal gland, which he attributed to an injury; he denied having had any venereal disease. About two years before McKisack saw him he noticed some weakness of the arms, but soon afterward observed that his neck seemed smaller than before. These defects steadily progressed until his condition on Oct. 13, 1909, had become as follows:

Mental faculties and the sensory apparatus are unchanged; pupil reflexes are normal; left knee-jerk is brisk; right knee-jerk is defective; wrist-jerks are absent; fundus oculi is normal; the blood shows a positive Wassermann reaction. The muscles of arms and shoulders are atrophied and weak. There are no fibrillary twitchings. There was atrophy of the latissimus dorsi, lower part of the pectoralis major and supinator longus, with escape of deltoid, infraspinatous and hand muscles—a characteristic picture of the juvenile type of muscular dystrophy. The muscles of the legs, pelvic girdle and lower back are intact.

Landouzy and Dejerine's type may be excluded by the complete absence of face lesion. The deltoids and infraspinati may possibly be regarded as hypertrophied, but this is probably a genuine hypertrophy from overwork rather than the degenerative false enlargement, so that the group of pseudohypertrophic paralysis may also be rejected. Absence of fibrillary contractions and of characteristic electrical changes, together with the distribution of atrophy, remove this case from the group of spinal muscular atrophies. In spite, therefore, of the comparatively advanced age (26 years) at which the disease commenced, and of the absence of hereditary influence, McKisack believes that this case may be regarded as an instance of Erb's juvenile form of muscular dystrophy.

11. **Action of Cutaneous Anesthetics.**—The authors believe that they have been able to obtain definite evidence that none of the drugs at present in use for painting on, or rubbing into the skin have any power to relieve pain. The use of belladonna, opium, aconite, menthol and cocain for bruises, thrombosis, inflammation or neuralgia should therefore be discontinued and replaced by more efficacious means, such as rest, massage and counter-irritation.

12. **Infantile Glaucoma or Buphthalmia.**—The patient, a girl, when first seen, was 6 months old. Both eyes were constantly "running water." The corneæ were large, the globes slightly prominent, and the intraocular tension decidedly high. It was impossible to examine the fundi, owing to the intense photophobia. When the patient was 3 years old, Allport performed an interior sclerotomy, but the incision was extended so as to cut entirely through the upper part of the intercalary region. The knife as it emerged from the sclera above the cornea was not allowed to cut through the conjunctiva, but this membrane was undermined for a few millimeters, producing a bridge of tissue which held the flap-like portion of the cornea in position. The idea of this operation was to obtain a scar at the filtration angle, which would be sufficiently loose and porous to allow the intraocular fluid to escape through it under the conjunctiva, and so produce a permanent drain. A small cystoid cicatrix developed at the upper point of the incision, and a minute fistulous opening in the sclera at this point could be detected. The tension soon became normal, and the symptoms gradually abated.

In September, 1908, a similar operation was performed on the right eye, with an equally satisfactory result, and in December of that year, the intraocular tension of both eyes was normal, the photophobia had completely disappeared, and the child could see very much better. She could readily perceive a pin lying on the floor some yards away, and had accurate color perception. The fields of vision were not markedly contracted. The child presents now an almost normal appearance, the eyes merely resembling the slightly prominent globes of a myope; she no longer complains of any eye symptoms.

15. **Peritoneal Blood Transfusion.**—The observations made by Boycott suggest that intravenous transfusion is to be preferred to intraperitoneal transfusion, as giving a prospect of more lasting benefit to the recipient.

24 *Breast Pang. H. W. Verdon.

16. **Polypoid Sarcoma of the Nose.**—Under this term Madden describes a tumor whose structure is that of sarcoma, but of such a low grade of malignancy as to produce comparatively little surrounding destruction, after a prolonged period of growth. Clinically, the sequence of symptoms appears to be polypous formation in both nostrils, leading soon to complete nasal obstruction; expansion of the cartilaginous portion of the nose, with marked hypertrophy of the overlying skin; and, later, marked thickening and infiltration of the columella and upper lip, with, finally, but only after a very chronic course, extension to surrounding parts.

18. **Failure of Heart.**—Colbeck maintains that in spite of the extravagant advocacy of hydrotherapy and special exercises in the treatment of cardiac failure, there is no therapeutic influence that compares in efficacy with physical and mental rest. The carrying out of this principle does not necessarily entail complete rest in bed; each case must be considered in the light of surrounding conditions with the object of ensuring a maximum of relief to the heart with a minimum of disturbance to the patient.

The duration of the period of rest is determined by the response of the heart to this method of relieving the ventricle of its overwork, and it is of the utmost importance that the resumption of exercise should be graduated with the greatest nicety and caution, since a small indiscretion in respect to the introduction of strain may undo the beneficial effects of weeks of treatment. Drugs have little or no direct influence for good in the treatment of failure of the heart due to exhaustion of the function of contractility without loss of tonus, and their indiscriminate use may be a source not only of harm, but of actual danger. So long as the cardiac tonus is maintained, the employment of digitalis and its allies is absolutely contraindicated. The justification, if any be needed, for the occasional hypodermic injection of digitalis during an emergency in the treatment of cardiac failure without loss of tonus is apparently found in the initial effect of the drug on the function of contractility. With this exception, he declares, the action of digitalis in cases of cardiac failure without loss of tonus is wholly deleterious. The harmful effects of the drug are most commonly observed in those cases of failure of the heart without loss of tonus that are not uncommonly found in association with high blood-pressure and cardiovascular sclerosis. In these circumstances, the failing function of contractility is working up to the full limit of its reserve power, and the introduction of any depressing factor, such as a full meal, a slight effort or the action of digitalis, may be sufficient to cause sudden stoppage of the heart. In failure of the heart with loss of tonus, the very remarkable restoration of the cardiac tonus that is commonly effected by digitalis enables the heart to regain control of the collection and discharge of its contents, and thereby to reestablish the balance of the circulation.

So long as the heart is dilated digitalis may be given with safety and confidence, and the administration of the drug in suitable cases of cardiac failure constitutes one of the most satisfactory examples of therapeutic intervention in the whole range of clinical medicine. Failure of the heart to respond to the action of digitalis implies either permanent dilatation of the organ, due to the stretching of a texturally altered myocardium, or to grave functional degradation (consequent on toxemic poisoning, etc.) of the cardiac wall.

24. **Breast Pang.**—Cases not infrequently come under notice in which the prominent symptom complained of is dull pain of an intolerable sort felt in the upper third of the chest, sometimes extending to one or both arms, and sometimes rising in the neck as far upward as the angles of the jaw. Usually, at first, the pain comes on when the patient is walking on rising ground. In later stages and in severe cases it begins before 50 yards of level ground can be covered. Verdon has seen a few cases in which the patient could not walk from one side of the room to the other without provoking a seizure. The attack is accompanied by a small, quick, irregular pulse, extreme pallor, and a sense of inability and distress. Sometimes a feeling of gastric distention pre[illegible]s the painful sensation, and eructation of flatus relieves

them. With a few exceptions these cases are uncomplicated by the presence of constitutional disease or any discoverable local lesion. Verdon shows that there are reasons for the inference that contraction of involuntary muscles of the arterial wall occurs during these attacks, and that contraction of arterial muscle is the cause of the pain and other phenomena connected with the seizure.

31 *Serodiagnosis of Pregnancy. (De la possibilité d'une toxémie villeuse et d'un séro-diagnostic de la grossesse, dans les premiers mois de la gestation.) G. Fieux and P. Mauriac.
32 *Acute Thyroiditis in Puerperal Infection. P. Lecène and Metzger.
33 *Hemostasis in Hysterectomy. (L'hémostase dans l'hystérectomie abdominale totale, l'hystérectomie subtotale ou en deux temps.) L. Chevrier.

31. **Early Serodiagnosis of Pregnancy.**—Fieux and Mauriac report research which seems to demonstrate that the young chorionic villi have a toxic action which induces the production of an antibody that can be revealed by the deviation of the complement in the hemolytic test. The vigorous growth of the chorionic villi during the first weeks of pregnancy seems to suggest that they possess certain features of a true parasitic graft, which may grow to a malignant tumor when the attack is too lively or the defense inadequate. This idea of syncytium intoxication from deportation of villi has been suggested as the origin of eclampsia. But the accidents due to the autointoxication of pregnancy are more severe as term approaches, while the growth of the villi becomes less and less active as the pregnancy continues. These and other facts observed suggest, they believe, that the villi may be responsible for the early toxemia; this assumption is sustained by the fact that the disturbances which mark the onset of gestation occur early; they disappear suddenly and completely if the ovum is expelled, extracted or dies; they subside and generally vanish completely by the close of the third or fourth month, but they may persist and with exceptional intensity in certain pathologic conditions of the ovum, with a vesicular mole, for instance. This, the authors assert, confirms the fact that in this toxemia the ovum rather than the embryo is concerned. In their experience, it was not in true pregnancy, but in cases of vesicular mole with proliferation of the villous element that the vomiting and cachexia were most pronounced. They apply the hemolytic test with an antigen made from villous masses derived from a two-months human ovum, taken from a patient with uncontrollable vomiting. With this and similar antigens they tested 55 pregnant women and obtained positive results in every case of pregnancy of two or three months' duration. The findings were negative in all the cases of pregnancy under one month and over four as also in 10 non-pregnant women, the latter including several with amenorrhea suggesting a possible pregnancy. The research described seems to establish, they think, the existence of an actual villi toxemia with a biochemical reaction permitting a serodiagnosis of pregnancy during the second and third month.

32. **Acute Thyroiditis in Puerperal Infection.**—Lecène and Metzger report a case in which a suppurative process developed in the thyroid a few days after delivery. The patient was 41 years old, a vii-para, and there had never been any disturbance in the thyroid. Prompt recovery followed incision and drainage of the abscess. A streptococcus was found in the lesion, the puerperium having been febrile. In a number of cases summarized from the literature the thyroiditis subsided under mild medical measures; in some cases the disturbances were ascribed to sore throat. The connection between the thyroid and the genital apparatus explains, they remark, the peculiar susceptibility of the thyroid to infection during the puerperium.

33. **Hemostasis in Hysterectomy.**—Chevrier gives an illustrated description of the technic which he advises, showing how to incise the vagina, etc., in regions free from blood vessels.

36 *Seventh Annual Campaign against Malaria in Algiers. (Etudes épidémiologiques et prophylactiques du paludisme.) E. and E. Sergent.

34. **Agglutination and Seroreaction in Mycoses.**—It seems evident from the research and experience reported that it is possible to differentiate actinomycosis by agglutination and the fixation of complement test using for the purpose spores of the sporotrichum; the actinomyces does not respond to the tests but there is a generic reaction with the spores of the allied sporotrichum. The latter can be easily cultivated and separated. The reactions also occur constantly in thrush with these spores, but there is no reaction in ringworm or aspergillosis.

36. **The Campaign Against Malaria.**—Sergent estimates the intensity of malaria in a place by what he calls the endemic index, that is, the percentage of malarial individuals who have much enlargement of the spleen. He here reviews the systematic campaign against malaria in Algiers in 1909.

41 *Circular Electrolysis. (Nouveaux procédés d'électrolyse circulaire.) L. V. Girolamo.
42 *Six Cases of Retrograde Catheterization of the Urethra. (Cathéterisme rétrograde hypogastrique.) M. Hache.

37. **Urethral Stricture.**—After reviewing the field in general, Batut reports the details of six unusual cases from his own experience as army surgeon. In one an obstinate stricture in the anterior urethra was the result of infection after circumcision; in another the stricture was due to a probably congenital membranous growth. Urethrotomy, both internal and external was required in all but one case in which linear electrolysis answered the purpose, with progressive dilatation for a recurrence ten years later.

38. **Stone in the Ureter.**—This profusely illustrated article is an abridgement of an address prepared for the last French urologic congress. Jeanbrau has compiled 239 cases of calculi in the ureter removed by operative intervention or expelled after catheterization (53 cases). Immediate and complete recovery can be counted on, he states, if the patient is capable of bearing general or spinal anesthesia and the operation is not done during anuria. A fistula need not be apprehended if the permeability of the ureter throughout its entire length is determined after extraction of the calculus. The mortality in the cases on record was 1.66 per cent. In examining, after subsidence of the attack of pain, a tender point should be sought along the ureter above or near the umbilicus, at the intersection of a vertical line passing through McBurney's point and a horizontal line passing through the umbilicus; a second tender point is at the intersection of a line uniting the crests of the ilium and a vertical line through the pubis. The point where the ureter enters the bladder is also liable to be tender. In only 2 cases was the calculus discovered by abdominal palpation, but palpation through the vagina usually gave instructive findings, especially when the patient was examined standing. In 13 cases the calculus was palpated through the rectum. In 29 cases cystoscopy permitted the true diagnosis when the symptoms seemed to locate the trouble in the kidneys or bladder. In all the cases reviewed recurrence was known in

only a single instance and this may have been merely that a stone was overlooked at first.

39. **Chyluria.**—Marion's patient was a man of 58 who had had gonorrhea in youth and occasional bronchitis. Recently the night urine has appeared milky and he has lost 23 pounds in weight. The day urine is clear but on reclining the urine is at once milky. The milky urine always comes from the right ureter. Bacteriologic tests are negative and there is nothing to suggest the possible presence of filariosis. A fistula from rupture of a lymphatic into the urinary passages is probably the most frequent cause, although secretory renal chyluria is not an impossible assumption. This case seems to favor the assumption of a communicating fistula, and treatment along this line has been instituted, a silver nitrate solution being instilled into the ureter and renal pelvis to promote the healing of the assumed fistula.

41. **Circular Electrolysis in the Urethra.**—Girolamo has found that the negative electrolysis has first a vasoconstricting and then a vasodilating action, followed by the formation of a soft eschar. The tissues of the urethra soften and become permeable for the cauterizing action on the points influenced by the electrode. The olive-shaped metal electrode should be a little larger than the largest caliber sound that can pass through the stricture; immediately after the electrolysis he introduces other electrodes, of increasing caliber, having a set of olive-shaped tips of various sizes. The urethra should be cocainized beforehand and the current should not be over 5 or 6 milliamperes during the five minutes it is used. After the dilatation he massages the region of the stenosis still under the influence of the current. This forced and rapid dilatation, he asserts, puts an end to the retention and hastens the cure. The electrolytic action is limited to the spot where it is needed, and can be done with and without the endoscope. The superposed massage utilizing the electrolytic ionization is an important factor in the rapid cure.

42. **Retrograde Catheterization of the Urethra.**—Hache reports 6 cases interesting from the multiplicity and severity of the lesions. In 2 cases there was a sliver of bone in the urethra from a fracture of the pelvis; in one the prostatic urethra had been torn out; in another 2 accidents at 20 years' interval involved the urethra; there was also a calculus in it.

43 *Spasmodic Paraplegia in Children with Inherited Syphilis. (Forme de paraplégie spasmodique d'origine hérédo-syphilitique chez l'enfant.) A. B. Marfan.
44 Blood in the S[illegible] the Intestines in Young Children. (R[illegible] les selles en pathologie intestinale.)
45 Staphylococcus [illegible] E. Weil and G. Mouriquand.

43. **Spasmodic Paraplegia in Children with Inherited Syphilis.**—In the case described by Marfan, the patient was a boy nearly 9 years old who was able to walk very slowly without support, but with a dragging gait, balancing himself first on one foot and then on the other. The entire limb was stiff, the hip, knee and ankle scarcely bending at all, the toes dragging and hitting against obstacles and the knees touching. He can walk in a straight line, however, without staggering, and closing the eyes does not increase the trouble in walking. When reclining, the paraplegia is less marked, and passive movements of the joints are possible. The tendon reflexes are exaggerated, and the Babinski and other signs indicate some lesion in the pyramidal tract in the dorsolumbar spinal cord. There are no sphincter disturbances or trophic lesions but the Argyll-Robertson sign is positive and the child is mentally backward. Marfan ascribes the trouble to inherited syphilis and advises commencing specific treatment at once in such a case without waiting for certainty as to the inherited taint. In his case treatment was not commenced until fifteen months after appearance of the first symptoms, and this delay was probably responsible for the entire lack of improvement under energetic mercurial treatment for eighteen months. The diagnosis was first rendered certain in this and another case by development of parenchymatous keratitis; this soon subsided under the specific treatment. The paraplegia in question generally develops late, at the age of 4, 5, 7 or 12 years in the cases he has encountered. The affection is much like that of syphilitic spinal paralysis in adults except that the sphincters do not seem to be affected.

46 *The Mathieu Indirect Method of Estimating Amount of Stomach Content. (Valeur de la méthode Mathieu-Rémond pour la détermination indirecte du volume de liquide contenu dans l'estomac.) A. Mathieu and Taillandier.
47 Coexistence of a Basement-Celled Epithelioma in the Esophagus and a Cylinder-Celled Epithelioma in the Stomach. (Les cancers multiples du tube digestif.) E. Parmentier and E. Chabrol.
48 *Parotitis during Medical Treatment of Gastric Ulcer. (Des parotidites survenant au cours de la "cure de repos stomacal absolu.") R. Gaultier.

46. **The Mathieu Method of Determining Amount of Stomach Content.**—Mathieu states that the experiences of the fifteen years since he introduced this method have confirmed its reliability. The principle is the comparison of the degree of acidity of the stomach content before and after dilution with a given amount of water. Laboulais and Goiffon have recently simplified the technic considerably. They use a titrated solution of sodium phosphate; after this is poured into the stomach and well mixed with the contents they withdraw some, and from its dilution then they estimate the amount of fluid present in the stomach.

48. **Parotitis During Treatment for Gastric Ulcer.**—Gaultier has encountered 2 cases of bilateral parotitis developing during dietetic treatment of gastric ulcer. He has found records of 21 other cases, including 4 with suppuration, fatal in 2 cases; one of his patients was in this last group. The suppression of the salivary secretion is manifestly the cause of infection of the glands, and during withdrawal of all food by the mouth measures must be maintained to keep the salivary glands functioning, or the contents of the excretory duct may be massaged out several times a day. Expression of this duct has recently been recommended in treatment of infectious angioparotitis, and it probably would prove effectual in prophylaxis. Merely keeping the mouth moistened and giving the patient scraps of ice have not proved effectual alone.

Archives de Médecine des Enfants, Paris

February, XIII, No. 2, pp. 81-160

49 *Pathogenesis of Rachitis. (Le rachitisme.) V. Hutinel.
50 *Study of the Temperature in Scarlet Fever. (Thermosémélologie de la scarlatine.) J. Barannikow.
51 The Deceptive Abdominal Onset of Certain Diseases of Children. (Cas de rougeole débutant par des symptomes abdominaux.) Oelsnitz.
52 Roseola in Cerebrospinal Meningitis. E. Merle.

49. **Rachitis.**—Hutinel regards a quantitative modification of the bone marrow as the essential feature of rickets. The qualitative changes are like those encountered in ordinary infections, he states, but the remarkable proliferation of the bone marrow seems to be specific for rachitis. The bone tissue also displays a tendency to evolutive dystrophy, which is also evident, although to a lesser degree, in all the tissues. This dystrophy may even involve the suprarenals, thymus, etc., but the anomalies in the glands may be regarded as the result of the nutritional disturbance responsible for the bone lesions, rather than as themselves the cause of the rachitis. The dystrophies that develop at puberty are akin to those in young children, both being in periods of exceptionally active nutrition. Pregnancy is another such period, and dystrophies are also liable to occur at these times, but they do not take the form of rachitis but of osteomalacia; the lesions are different according as the tissues are immature or adult. The primal disturbance responsible for the rachitis may include microbian, toxic and dystrophic factors, associated or superposed. For example in a child with a tendency to rachitis from defective feeding, other causes, such as an intercurrent infection, may conspire to aggravate this tendency.

50. **Study of Temperature in Scarlet Fever.**—Barannikow believes that it is possible to determine the prognosis early in scarlet fever by the temperature curve, and he gives the findings in 209 cases, comparing them with the composite

curves made out retrospectively from the mild, the moderate and severe cases. A deep fall in temperature between the third and thirteenth day was characteristic of every epidemic observed. It may occur suddenly or the temperature may be two or three days in declining. This fact is important in estimating the action of serotherapy. In his experience, scarlet fever developing in the course of whooping cough was always exceptionally *mild.* He could not discover any connection between the duration of the fever and heart complications, but such was unmistakable between inflammation of the tonsils and the heart complications as well as with the general symptoms—all being more severe the more intense the tonsillitis, but no connection of the kind could be discovered with the nephritis.

53 *Research on Anatomy of the Small Intestine and its Mesentery. (Notes d'anatomie sur l'intestin grêle et le mesentère.) A. Latarjet.
54 *Echinococcus Disease of the Lung. (Kyste hydatique double du poumon droit.) H. Albertin and F. Barjon.
55 *Eight Cases of Laryngostomy with Dilatation. C. Viannay. Commenced in No. 1.

53. **Anatomy of the Small Intestine and Mesentery.**—Latarjet gives an illustrated description of various points in regard to the anatomy of the small intestine and its mesentery, seeking to locate the special loop of the intestine under examination and its possible torsion from the findings in regard to the arteries and veins and fat deposits.

54. **Echinococcus Cyst of the Lung.**—In the case reported one cyst was in the apex and another in the base of the same lung; both were readily shelled out, with the complete recovery of the patient, a woman of 40. She had suffered from cough and labored breathing for about six months; after three months revulsion had been applied to the chest for pleurisy. She had lost nearly 25 pounds in weight but there were no night sweats and no pain until the last two weeks when there had been intermittent sharp pains in the right side and liver region. Roentgen-ray examination revealed the two tumors, and first one and then the other, ten months later, were successfully removed, two or three ribs being resected each time. There was a history of urticaria seven years before, and this first suggested the possibility of echinococcus disease; the urticaria may have been due to elimination through the skin of the poisons generated by the parasite in the blood, the elimination ceasing as the parasite located in the lung and became encysted. There was no hemoptysis at any time.

55. **Laryngostomy with Dilatation.**—All of Viannay's 8 patients are in good health to date except that one patient succumbed to an accidental pneumonia six months later. He reviews the cases in detail with the technic. He prefers to close the wound definitely at once when possible.

56 *[illegible] Prognosis of Uremia by Amount of Urea in [illegible] Fluid. J. Froment.

13, No. 7, pp. 337-392

57 Treatment of Vaginal Cystocele or Preuterine Hernia. H. Violet.

56. **Urea Content of Cerebrospinal Fluid in Uremia.**—Froment tabulates the findings in regard to the proportion of urea and chlorids in the different organic fluids in 18 cases of various affections with more or less uremia. Of all the changes in the cerebrospinal fluid in case of uremic poisoning of the nervous system, an increase in the proportion of urea is the most constant and the most instructive. Even 1 per cent. is suspicious, but with more than this, uremia is beyond question, and with 4 per cent. the prognosis is inevitably fatal. The uremia is seldom fatal when the proportion is only 1 or 2 per cent., except possibly in children with acute nephritis. The urea content in the other organic fluids is less constant and not characteristic.

60 *Scarlet Fever. (La scarlatine à l'hôpital Claude-Bernard in 1908. II.). A. Gouget.
61 *Hemophilia III. P. Nolf and A. Herry.
62 Farm Colonies for Epileptics, etc. (L'assistance spéciale des épileptiques et débiles adultes par le retour à la terre.) A. Marie.
63 Distribution of Sugar in Elements of Diabetic Blood. (Repartition du sucre dans le plasma et les globules du sang chez un diabétique.) R. Lépine and R. Boulud.

60. **Scarlet Fever.**—Gouget describes the erosive or ulcerative type of sore throat which he encountered in 48 of the 858 cases of scarlet fever at the isolation hospital in 1908. In the 28 cases with ulceration, 11 of the children died and the survivors all developed otitis or other serious complication. No local measures displayed any efficacy. He also reviews the other complications observed. The total mortality in the 858 cases was 30.

61. **Peptone to Arrest Hemophilic Hemorrhage.**—In 9 cases hemophilic hemorrhage was arrested by injection of 10 c.c. of a 5 per cent. solution of peptone (Witte). In some of the cases 2 injections were made as a prophylactic measure the first 10 and the second 2 days before a major operation. In one case hematuria was arrested by one injection; the patient succumbed to hematemesis a year later. The patients were between 6 and 67 years old, and a single injection answered the purpose in nearly every case. The peptone seems to be more energetic and it is more easily sterilized than serum; heating to 120 C. (248 F.) for an hour does not alter its properties. It is injected as a 5 per cent. solution in a 0.5 per cent. solution of sodium chlorid. There seems to be no danger of anaphylaxis. For local application an extract of lymphoid organs, spleen, lymph glands and thymus, seems to be as effectual as fresh serum. The extract can be made with organs from the slaughter-house by triturating them with a little sand, adding to 1 part of the gland 2 parts of a 0.09 per thousand sodium chlorid and 0.5 per thousand calcium chlorid solution, and then straining. The action and effect of the peptone seems to be identical with that of fresh serum, but judging by the experiences to date, the authors state, the action seems to be much more pronounced.

Semaine Médicale, Paris

March 2, XXX, No. 9, pp. 97-108

64 *Advisability of Surgical Intervention for Cystic Degeneration of the Kidney. (Faut-il opérer le rein polykystique?) F. Lejars.
65 *Is Hegar's Sign Pathognomonic of Pregnancy? (Le signe de Hegar est il pathognomonique de la grossesse?) R. de Bovis.

64. **Indications for Operation in Cystic Degeneration of the Kidney.**—Lejars regards nephrectomy as justified in case of suppuration, pain, hematuria or intracystic hemorrhage, if the condition of the other kidney permits. Cystic degeneration is generally bilateral but it may be in an initial stage in the second kidney and thus allow long survival after the nephrectomy, as the process is of very slow development. Unless there are severe symptoms, however, he does not advise nephrectomy as the kidney may retain for many years functional capacity sufficient to ward off severe symptoms even when in advanced cystic degeneration. He removed three years ago a polycystic tumor which he supposed was the kidney but which proved to be of pararenal origin; both kidneys were also in polycystic degeneration as was discovered at autopsy not long afterward. Differentiation even during the operation may be difficult. In another case he found a knobby, blackish cystic tumor originating in the lower end of the kidney. Supposing that the trouble was general cystic degeneration of the organ, and not knowing the condition of its mate, he did not dare to remove the kidney but resected it into sound tissue and the patient recovered. The tumor proved to be an epithelioma. Palliative operations on cystic kidneys are attended with great risks, he declares, and should never be done except under compelling indications, but then may give great relief.

65. **Hegar's Sign of Pregnancy not Reliable.**—De Bovis asserts that softening of the isthmus of the uterus cannot be regarded as pathognomonic of pregnancy as it has been encountered with a myomatous uterus. The softening may vary widely in intensity, extent and location. Hemorrhages should not be accepted as evidence for or against the presence

of a myoma. In three cases in his experience the women had hemorrhages more or less continuously for one, three and five months and were then delivered of a dead or living fetus; no trace of a myoma could be discovered.

75 Seroreaction in Cadavers. (Leichensera und die Wassermannsche Syphilisreaktion.) R. Krefting.

66. **Inflammatory and Lithogenous Jaundice.**—Riedel emphasizes the necessity for differentiating jaundice resulting from the presence of stones in the gall-bladder or cystic duct, which he calls the inflammatory form, and that resulting from a stone in the common bile duct, the real lithogenous form. He cites a number of examples to confirm his assertion that a patient with inflammatory jaundice cannot be operated on too quickly; a stone in the neck of the gall-bladder or in the cystic duct may be pushed along into the common bile duct, so that out of the hitherto harmless local affection a general disturbance may result. On the other hand, the patient with the real lithogenous jaundice should not be operated on at once at the first attack; the stones may be passed without further trouble. Only exceptionally serious infection compels immediate surgical intervention. In his experience with 600 operative cases of jaundice, in 80 per cent. of the cases the first attack of gall-stone colic was due to hydrops or infected hydrops in the gall-bladder; in 20 per cent. bile was found in the gall-bladder. About 57 per cent. of the patients had a primary large stone in the neck of the gall-bladder or cystic duct; in 43 per cent. there were numerous small stones. In about 90 per cent. of the cases in which the stones remained quietly in the bladder or cystic duct there was no jaundice. The majority of patients thus have no jaundice at their first attack of gall-stone colic, but in 10 per cent. of such cases there is jaundice even when the stone remains in the neck of the gall-bladder or in the cystic duct. The jaundice in this case is of inflammatory origin, although generally aseptic. It is the result of propagation of an inflammation from the gall-bladder to the liver. If the stone is high up in the cystic duct, it may compress and kink the lower biliary passage, thus superposing a mechanical element on the inflammation. In conclusion he reiterates that patients with violent attacks without jaundice and without passage of stones, and those with inflammatory jaundice should be operated on during the attack. With the real lithogenous jaundice commencing independently, conservative treatment is indicated unless severe infection compels rapid intervention.

67. Abstracted in the Berlin Letter in The Journal, March 12, 1910, page 886.

71. **Influencing of Cardiac Neurosis by Correction of Anomalies in the Nose.**—Koblanck gives the description of a case written by the patient himself, a physician, aged 31, who had suffered for years with a cardiac neurosis with attacks simulating angina pectoris. Removal of some polyps in the nose and electrolytic correction of an abnormal protruding part of the septum were followed by complete subsidence of all the trouble. The young physician had become convinced by his symptoms that a large part of them were due to participation of the sympathetic system. The benefit from direct treatment of the sympathetic fibers in the nose confirms this.

76 *Menthol in Treatment of Pulmonary Tuberculosis. Stepp.

76. **Menthol in Pulmonary Tuberculosis.**—Stepp gave the menthol internally at first, but with disappointing results. Since then he has applied it in the form of inunctions, and reports good results. He uses a 30 or 40 per cent. menthol salve. Some of the salve is rubbed into the skin for ten minutes until it is entirely taken up, a different part of the body being anointed each time. He has never observed any inconveniences from the method but found benefit follow in the 14 cases in which he has applied this method of treatment perseveringly for four or five months. He gives the details of the cases. Improvement is evident, he asserts, after two or three weeks and continues to progress until the patients are practically cured, except in the more advanced cases and improvement is evident in every case. Acute tuberculosis either of lungs, glands, or bones, is not amenable to this treatment, but it is effectual in the infiltrations left after acute pneumonia in children. These relics of the pneumonia are generally tuberculous processes, and they yielded rapidly and completely to the menthol treatment in his 18 cases of this kind. He explains the action of the menthol as due to its elimination by the lungs after it has been taken up by the lymphatics; this enables it to act directly on the tuberculous tissue in the lungs. As this is absorbed, the walls of the cavity may sink in and the cavity thus become obliterated. It is even possible that a kind of autoimmunization may follow.

87. **Family Typhoid with Initial Hemorrhagic Exanthem.**—Curschmann reports the case of a mother and six children all coming down with typhoid at the same time and presenting on the second or third day a sudden eruption of petechial spots. The typhoid was mild and there was nothing to suggest true exanthematous typhus. The father of the family developed the disease two or three weeks after the others, with fatal ulceration in the intestines. He presented an eruption of hemorrhagic vesicles. The other patients recovered; constipation had been the rule in all but two.

88. **Congenital Hydrops.**—Schridde has encountered 3 cases in the last 5 years in which a general hydrops was associated with extreme anemia and enlargement of the heart. In 2 of

the cases the mothers had had severe nephritis. He is convinced that many cases which have been reported as pseudoleukemic anemia in an infant, have in reality been of this type. Examination of the blood in cases of congenital edema may throw further light on the condition.

89. **The Momburg Belt Constriction for Segregation of the Urine.**—Hoehne found that it is possible by applying a splint over half of the abdomen to protect this half against constriction by the rubber tubing wound around the waist according to the Momburg technic. This allows the ureter on the protected side to continue its functions undisturbed, while the ureter feeling the constriction is closed. This permitted instructive oversight of the functioning of the kidney and ureter on the protected side in rabbits, and suggests the possibility that the method may prove useful in clinical diagnosis. He found that the compression of the ureter by the Momburg belt induced injury of the kidney, with albuminuria and tube casts. These disturbances were transient in a case reported in detail in which the belt was applied for the purpose of inducing abortion. The latter was not realized, showing that the constriction does not shut off all the blood supply from the genital apparatus. The transient injury of the kidneys observed in this case suggests possible danger from this source if the constriction is kept up for a long time; half an hour should be the average.

90. **Care of the Teeth.**—Herrenknecht reviews bacteriologic research which shows that the normal bacterial flora in the mouth protects against the invasion of pathogenic germs under normal conditions. The bacteria do not injure the teeth unless their products are allowed to accumulate, in which case the acids generated by the bacteria cause the destruction of the teeth. The main point in the care of the teeth is therefore to insure the mechanical removal of these products and everything that may serve as nesting places for the bacteria. The most important measure is to rinse out the mouth with water or a weak salt solution; warm water is much more cleansing than cold. No bactericidal drugs are needed; they do direct harm as they injure the tissues; all that is necessary is the mechanical, forcible rinsing out of the mouth several times in succession after each meal. If a mouth wash is desired to aid in cleansing, and to leave a refreshing taste in the mouth, he prescribes a mixture of 0.2 part saccharin and 0.3 part peppermint oil in 100 parts alcohol. From 10 to 20 drops are to be added to a glass of warm water and the whole amount used to rinse the mouth. He rejects tooth powders as liable to injure the teeth from hard particles. Soap also has an injurious action. He advises having the teeth inspected several times a year after the age of three, and protests against pulling a molar or premolar tooth in a child's mouth; if absolutely necessary, the antagonist should be pulled too. This should be the rule up to the age of 18; the jaws will then develop symmetrically. Adults should have the teeth examined twice a year and in some cases oftener.

91. **The Meiostagmin Drop-forming Reaction in Cancer.**—Ascoli reports positive results in tests of the drop-forming property of the serum in cancer. In 29 cases of carcinoma and 2 of sarcoma there was a difference of from 4 to 8 drops after addition of the specific antigen, while in 28 control cases the number of drops showed no change. The meiostagmin reaction may thus prove a reliable sign of malignant disease if the experience of others confirms his findings.

92. **The Pupils in Young Infants.**—Gudden calls attention to the sudden and maximal dilatation of the pupils on sudden waking from sleep as a psychic reflex, possibly possessing some differential value for cortical affections, especially in infants.

102. **Treatment of Air and Fat Embolism.**—The Journal, Feb. 12, 1910, page 576, mentioned Schanz's method of injecting large amounts of salt solution in treatment of fat embolism causing convulsions in the course of orthopedic operations. Schanz explains the disturbances as the result of obstruction of the capillaries of the brain by the particles of fat. The saline infusion washes them along. Now von Lesser calls attention to his experimental experiences with air embolism; he found that the heart was unable to contract over air as the valves are meant to act on fluids and not on air. After the heart action had ceased after injection of air in the jugular vein, he was able to revive it again by direct injection of 0.5 per cent. salt solution directly into the right ventricle.

103. **Operative Separation of Horseshoe Kidney.**—In Martinow's case a nurse, aged 49, had complained since childhood of diagreeable pulsation in the abdomen and for some years had had typical pains above the umbilicus, and also constipation. The nerves had become more and more involved and the patient had been treated for hysteria for some years. Palpation revealed a tumor above the umbilicus, the entire region was very tender; at times the tumor increased in size and the pulsation in the region became more violent. The kidney region was not tender and all the other organs seemed to be normal. On the diagnosis of pancreas tumor or horseshoe kidney the abdomen was opened. The tumor lay on the aorta and united both kidneys. He severed this bridge between the kidneys, between two soft bowel clamps. This released the aorta as the two halves of the kidney separated and all disturbances ceased at once.

112. **Etiology of Pellagra.**—Verney emphasizes the fact that in Italy pellagra has followed the introduction and cultivation of maize and also that rainy seasons, with defective development of the grain, are followed by increased prevalence and severity of the disease, and, further, that the use of well dried and healthy maize has reduced materially the incidence of the disease. Another important fact is that the symptoms of the disease are analogous to those observed in other chronic intoxications such as poisoning by lead, phosphorus, arsenic, mercury and alcohol. The analogy is still closer with chronic alimentary intoxication such as from ergot poisoning, chronic favism, the *phlegma salada* of the Spaniards, attributed to spoiled wheat, the cachexia observed in Paris during the last siege, and other chronic disorders due to defective food. At the last Itelian neurologic congress, on the other hand, Mondino reported two typical cases of pellagra in persons who had never used maize, and Neusser in Roumania has also encountered individuals with pellagra who had never eaten maize. But Neusser discovered that his patients were in the habit of drinking brandy made from spoiled maize and Antonini confirmed this fact in his experience at Friuli. Verney and also Gosio claim that the theory of spoiled maize does not apply to all the cases of pellagra; some other etiology must be admitted for certain cases, and there is also a probability that a syndrome may be observed closely simulating pellagra which yet is not pellagra. The idea of an intoxication, moreover, Verney continues, seems to be refuted by the persistence of the disease unmodified by avoidance of corn in the diet. No other intoxication is known which does not show a change for the better when the source of the intoxication is withdrawn. The existence of chronic, acute and fulminating cases of pellagra harmonizes better with the conception of an infection rather than an intoxication, even admitting that in certain cases the syndrome may be the result of superposed malaria, typhoid or meningitis. On the whole, he concludes, there is much to sustain the assumption that pellagra is an infection, and a protozoan infection in particular. The toxic and the infectious theories are not antagonistic but reenforce each other. The digestive disturbances induced by the spoiled corn favor intestinal derangement or there may be some toxic element. The resulting syndrome is not pellagra but the condition predisposes to pellagra, as also any other conditions entailing impoverished blood and lowered resisting powers. His conclusions are, therefore, that pellagra is an infection which develops independently when once it gets a hold in a debilitated organism.

114. **The Pneumococcus in the Conjunctival Secretion in Pneumonia.**—Crispolti found pneumococci in the conjunctival secretion in 40 out of 45 cases of pneumonia. They were numerous during the first five days but then became rarer and atypical forms predominated. In the 5 cases in which the conjunctival secretion contained no pneumococci, none was found in the sputum, and the pneumonia was probably due to some other germ, probably the influenza bacillus.

115. **Registration of Respiratory Movements by Injection of a Gas.**—La Franca reports experiments on dogs with air or various gases injected into the pleura, recording on a drum the respiratory movements afterward as they were modified by the pneumothorax.

118. **Constriction Hyperemia.**—Rabbits and guinea-pigs injected with virulent germs and then having constriction applied to the limb above seemed to die more quickly than the controls; even a sublethal dose became fatal under these conditions. On the other hand, recovery was promoted by the constriction hyperemia when the infection was with germs of comparatively slight virulence. Injection of typhoid and cholera germs, with the part shut off from the arterial circulation by the constricting band, induced a local production of antibodies having a destructive action on the germs. The induced hyperemia is not always accompanied by an accumulation of leucocytes in the part; they may even be less numerous than elsewhere. It seems to be evident that a number of factors combine to produce the beneficial results observed under suitable conditions with the induced hyperemia; no single element is responsible for them.

125. **Colloid Cystoma of the Ovary.**—Ahlström's article fills 276 pages and is accompanied by 7 plates and 8 tables of details regarding 81 cases from the literature, including 49 with microscopic findings. He also reports in detail 9 cases from his own experience with microscopic examination and 19 cases without this. The ovarian colloid cystoma is shown to be on the borderline between malignant and benign growths, and should no longer be regarded as inevitably benign. Proliferating epithelial metastasis, he asserts, is the principal feature of the process after perforation of the cystoma into the peritoneum. The proliferating epithelial cells of the colloid cystoma perforating the cyst-wall and invading the peritoneal cavity display a varying intensity of metastatic growth, but they seem to find an especially favorable medium in the omentum for almost malignant proliferation. In removing a primary colloid cystoma the colloid masses in the peritoneum should be wiped away, but it is not necessary to detach them with an instrument. The omentum should be resected wherever there are colloid deposits or changes in it. The frequent development of a cystoma in the other ovary, observed in nearly a third of the 32 cases in which the patients were traced for a number of years, suggests the importance of removing both ovaries. He was unable to discover any anatomic features as index of a specially energetic proliferating power on the part of the cyst epithelial cells; possibly the outcome may depend on the resisting power of the part of the peritoneum involved; the omentum seems to display much less resistance than other regions. Even in case of metastases, long survival may follow their excision. Implantation metastasis may occur even without naked-eye rupture. In about 27 per cent. both ovaries were affected, and in nearly 10 per cent. the second ovary became affected later. In about 20 per cent. the cystoma involved a ligament. Epithelial metastasis was evident in all of Ahlström's cases and in 57.1 per cent. of those on record. It was evident further that the colloid deposits exert a destructive action on connective tissue. One of his cases is, he believes, the first on record in which metastasis occurred in lymph glands outside of the abdominal cavity (above the diaphragm and in the groin).

126. **What Does a Gastroenterostomy Accomplish?**—Pers' previous communication on this subject was summarized in THE JOURNAL, Dec. 11, 1909, p. 2045.

127. **Course and Outcome of Renal Tuberculosis.**—Ekehorn has been studying the conditions and course of advanced tuberculosis in the kidneys in 33 cases with operative or autopsy findings in a number. Eight of the patients without operative treatment are still living, and 4 have entirely recovered so far as subjective symptoms are concerned; the urine is clear in one patient but there are signs of amyloid degeneration of the kidney in two cases notwithstanding the lack

of subjective symptoms. All the patients who recovered were young, 5, 11, 19 and 19 years old respectively; the interval since averages 8 years. His material, he declares, confirms anew the importance of prompt nephrectomy as the only correct treatment. The relative improvement noticed in a number of cases after a time is deceptive. It means only that the tuberculosis in the kidney first attacked has reached the end of its active manifestations, the kidney then being largely or totally destroyed. But by this time there are usually manifestations of the disease elsewhere. Spontaneous arrest of the disease did occur in one of his cases after the kidney in question had become totally destroyed. The complete transformation of the kidney into a sterile sclerotic tissue with the flickering out of the last trace of vitality in the germs realized a kind of autonephrectomy after which the tuberculous lesions in the ureter and bladder below healed.

128 *Dulness over the Right Apex of the Lung not due to Apical Lesions. (Om falsk Dæmpning over højre Lungespids.) H. I. Bing.

128. Dulness Over the Right Apex Not Due to Apical Lesions.—Bing calls attention to the dulness which increases as percussion is carried outward toward the side, and he presents evidence to prove that it is due to enlarged bronchial glands on the right side while the apex of the lung may be entirely normal. This is the dulness which Krönig found in mouth-breathers and which he ascribed to the adenoids and resulting disturbances. Bing shows that adenoids generally are accompanied by enlarged glands elsewhere, and especially in the bronchial chain, and that the real cause for the dulness is the peculiar arrangement of the bronchial glands on the right side where they are more numerous, higher up and occur in groups instead of being scattered isolated as in the left side. The dulness can be readily differentiated from that with tuberculous infiltration or retraction of the apex by its location, its distinctness under Goldscheider's, barely audible, "threshold" percussion and by the characteristic areas of dulness of different degrees in the front and back of the chest. He gives a number of illustrations of the areas involved and of the arrangement of the right bronchial glands, their preponderance, and the larger size and higher location of the bronchi on this side, his clinical experience confirming in every respect the arrangement of the tracheobronchial glands as depicted by Sukiennikow.

A LARGE CYSTIC TUMOR DEVELOPING FROM THE ILIOPSOAS BURSA

CONTAINING LARGE FREE CARTILAGINOUS MASSES, AND COMMUNICATING WITH THE HIP-JOINT

THOMAS S. CULLEN

BALTIMORE

History.—In November, 1908, I was asked by Dr. A. H. A. Mayer to examine a man aged 46 who had what appeared to be a very unusual pelvic tumor. About ten years before the patient had begun to limp, and a year later consulted a physician who told him that he had a tumor of the left hip. The condition gradually had become worse. For about a year the man had noticed that every time he put his weight on his left leg "something slipped" in his hip.

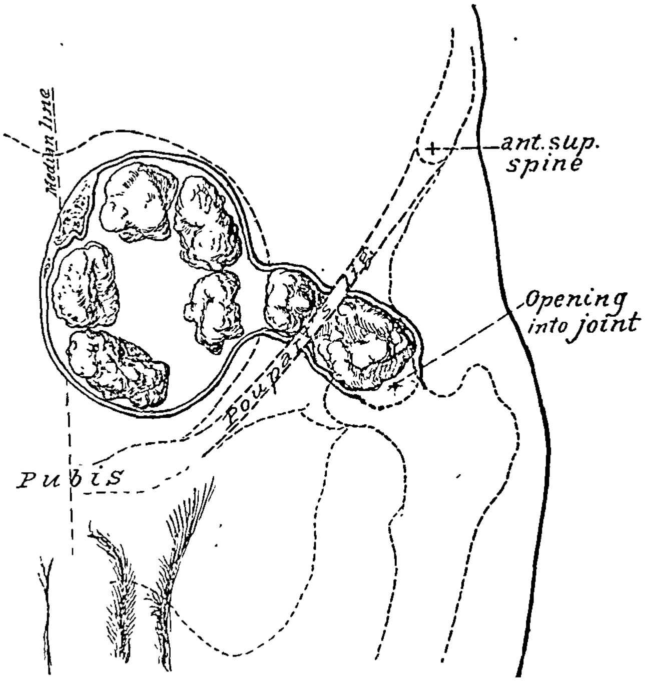

Fig. 1.—A cystic tumor developing from the left iliopsoas bursa containing large free cartilaginous masses and communicating with the hip-joint. Occupying the left half of the pelvis is a cystic tumor which on its outer side was firmly attached to the pelvic wall. The cyst walls were composed chiefly of fibrous tissue. The thickening in certain areas noted in the walls is due to deposits of bone. The cyst cavity was distended with clear yellowish, tenacious fluid and also contained five free and irregular cartilaginous masses. A narrow prolongation of the cyst passed downward and forward beneath Poupart's ligament and opened directly into the hip-joint. Filling this portion of the cyst was a large free cartilaginous mass. All the cartilaginous masses are shown in their natural size in Fig. 3.

Examination.—The patient was a tall, rather anemic looking man. The chest sounds were normal. The left leg was stiff and when walking he held the left hip-joint as immobile as possible. Occupying the left iliac fossa and extending beyond the median line was a firm oval mass, 8 by 10 cm. This was continuous with a smaller mass which passed below Poupart's ligament and extended to the left of the hip-joint anteriorly. The large mass seemed to fill the left half of the pelvis. In some places it appeared to consist of bone, but at other points felt cystic. It seemed to be intimately connected with the pelvic bone. The glands in both groins were palpable. The left leg was three-quarters of an inch shorter than the right. On flexion of the leg the pelvic mass receded somewhat, but on extension the tumor again became prominent. Flexion, extension, adduction and abduction were accompanied by dull crepitation in or near the hip-joint. On carefully questioning the patient it was learned that the swelling had been first noticed just below Poupart's ligament.

Operation.—An incision was made just above and parallel with Poupart's ligament and the extraperitoneal tumor exposed. After displacing the anterior crural nerve, which was markedly stretched over the tumor, and splitting the muscle which lay over it, it was found necessary to sever Poupart's ligament as a portion of the tumor lay beneath it. The pelvic portion of the mass was loosened up easily on its anterior and posterior aspects, but on the outer side was firmly attached to

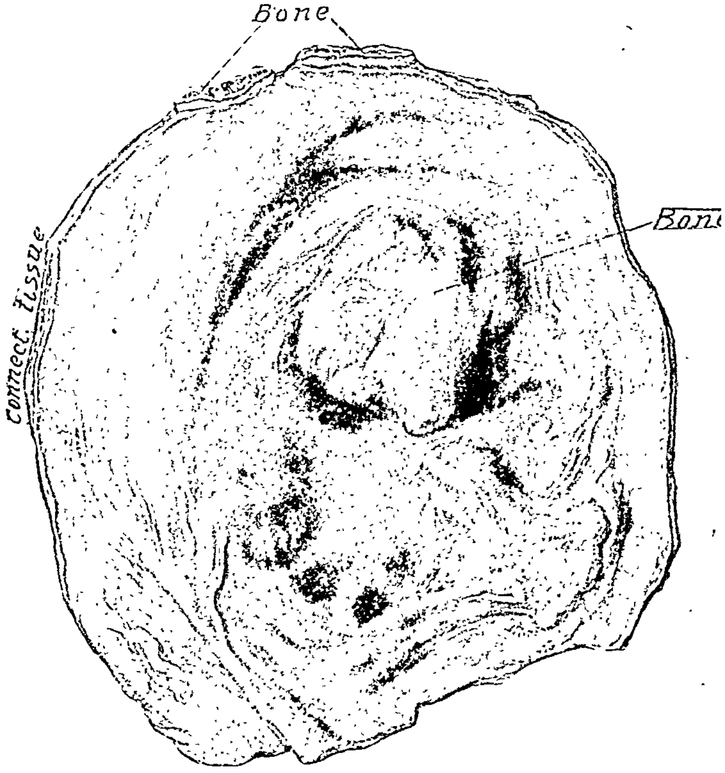

Fig. 2.—Part of the sac of a cystic tumor developing from the iliopsoas bursa. The picture represents the inner surface of the cyst. The walls vary from 1 to 2 mm. in thickness and in them are seen cross sections of plaques of bone. In other portions of the walls cartilage was noted. The inner surface presented a distinctly trabeculated appearance evidently due to the uneven stretching of the sac. Projecting into the cavity is an irregular bony mass fully 3 cm. in diameter. The sac was lined with a smooth glistening membrane; it contained clear yellow tenacious fluid and the six cartilaginous masses depicted in Fig. 3.

the ileum, and below seemed intimately related to the anterior portion of the hip-joint. After being walled off with gauze it was opened and there was an escape of clear viscid fluid, yellowish in color. Lying free in the cavity were five irregularly lobulated, hard cartilaginous masses (Figs. 1, 3). After these had been removed a sixth was found fastened down beneath Poupart's ligament. When this nodule had been taken out a finger carried downward and forward passed directly into the hip joint anterior to the head of the femur. The bones of the joint were perfectly smooth. The pelvic sac was gradually dissected free at a point considerably below Poupart's ligament. It was then cut away and the remaining portion which formed the margin of the entrance into the joint was trimmed, turned in on itself, and snugly brought together with catgut sutures, thus securely closing the hip-joint. A small drain was laid in the upper angle of the wound far removed from the joint and the incision closed.

Result. — For a few days the patient did remarkably well but then became delirious and talked incoherently. It was learned that on a previous occasion he had shown similar cerebral disturbances and that it had been necessary to confine him for a time in a sanitarium. Dr. Henry J. Berkley, who saw him in consultation, felt that his mental condition had nothing to do with the operation. The wound after draining for a few days closed completely and the patient left the hospital in excellent physical and mental condition five and a half weeks afterward. He was able to walk without much difficulty.

Subsequent History.—Dec. 6, 1909: Dr. Mayer informs me that the patient occasionally has some discomfort in his leg but no pain in hip-joint. He still uses a cane.

Description of Specimen.—The walls of the sac were composed of fibrous tissue and scattered throughout them were plaques of cartilage and definite bony masses (Figs. 1, 2). Some of these fragments of bone were very small; others reached 3 cm. or more in diameter. The inner surface of the sac presented a trabeculated appearance (Fig. 2) evidently due to the unequal and gradual distention of the cystic tumor. Notwithstanding the uneven appearance the inner surface was everywhere covered by a smooth membrane. The fluid contents were clear, yellowish in color and rather sticky. The six irregular, white, cartilaginous masses filling the cavity are shown in their natural size in Figure 3. They were lying perfectly free and five of them popped out as soon as the sac was opened. The sixth could not escape as it was firmly held down by Poupart's ligament and its lower end entered the hip-joint.[1]

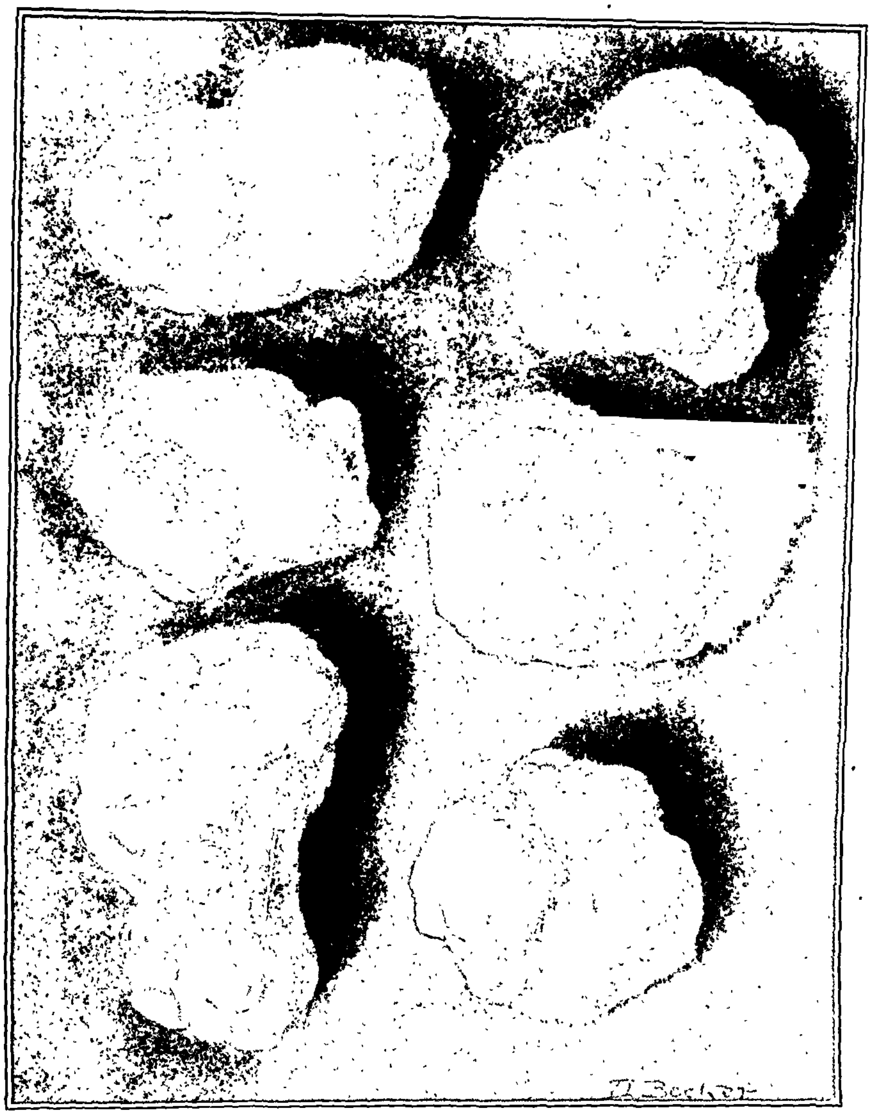

Fig. 3.—Cartilaginous masses lying free in a cystic tumor developing from the iliopsoas bursa (natural size). These masses were pearly white, very irregular, but perfectly smooth. They were rather lighter in weight than bone. Their general arrangement in the cyst is shown in Fig. 1.

ORIGIN OF THESE CYSTIC TUMORS

One of the largest, if not the largest, bursa in the body is that situated beneath the tendon of the iliopsoas muscle. This complex muscle arises from the body of the twelfth dorsal vertebra, from the bodies of all the lumbar vertebræ, from the transverse processes of all the lumbar vertebræ and from the iliac fossa. The combined tendon is inserted in the trochanter minor. In order to reach this the iliopsoas muscle must curve around the crest of the ilium. It is beneath the muscle where it curves over the bone that the bursa is found. It lies beneath Poupart's ligament below and lateral to the iliopectineal eminence. According to some authors it may attain the size of a hen's egg.

According to Joessel[2] the iliopsoas bursa or the bursa mucosa subiliaca lies between the partly tendinous portion of the iliac muscle and the front of the iliopectineal eminence. Anteriorly, it is firmly attached to the iliopsoas muscle, posteriorly to the iliopectineal eminence, and likewise to the thin portion of the capsule of the hip-joint.[3] It is bounded on the outer side by the iliofemoral ligament, below by the pubofemoral ligament and on the inner side by the cotyloid ligament.

Joessel further finds that occasionally the fibrous capsule at the thin point of the joint is wanting and then nothing but the synovial membrane separates the joint from the bursa. Occasionally the synovial membrane is lacking at the thin point and in these cases there is a direct communication between the hip-joint and the bursa. This opening explains how purulent accumulations of the joint may extend to the iliopsoas bursa and then appear under the iliopsoas muscle and also how psoas abscesses may travel down the muscle and eventually cause involvement of the hip-joint. An extended consideration of the subject would necessitate a discussion of practically all diseases of the hip and would naturally lead us too far afield. I shall consequently limit my remarks chiefly to those cases in which cystic tumors similar to this have been noted and in which little or no evidence of inflammation has existed.

---

[1] The specimens were demonstrated to the class and then drawn. During my absence in Europe they were unfortunately mislaid and have not yet been located; consequently I have thus far been unable to make a careful histologic examination to determine definitely whether the central portion of the cartilaginous masses contained bone or not.

[2] Topographisch-Chirurgische Anatomie, i, 169.

[3] This thin spot is well seen in Figure 232 of Cunningham's Anatomy, 1909, p. 296.

When consulting the literature I found a most instructive and painstaking article on "Diseases of the Bursæ of the Hip" by R. Zuelzer.[4] I have examined in the original the references given by this author and have found them in the main so well epitomized that I shall draw largely on his descriptions and conclusions.

It has been noted that the bursæ that are regularly found are usually developed during fetal life, while the less constant ones appear at a later date. Virchow and Schuchardt found that the small subcutaneous bursæ developed out of a connective-tissue network resembling cavernous tissue. Eventually a cavity was formed in which as a result of the continuous movements and rubbing the connective tissue gradually atrophied. The walls of these bursæ consist of dense connective tissue and contain a very little elastic tissue. The inner surface is lined with one layer of so-called endothelium and the contents of the bursa resemble those of the joint. They are slightly tenacious, thick and usually just enough in amount to keep the walls of the sac smooth.[5]

CASES OF CYSTIC DEVELOPMENT OF THE ILIOPSOAS BURSA AS COLLECTED BY ZUELZER

Hoffa: The patient, a workman, was struck on the right foot and the left arm. He walked home at once a distance of about two miles, remained without treatment for fourteen days and again went to work. A year later he complained of pain in the region of the right hip. On examination the leg was found slightly flexed, abducted and rotated outward. At the hip was a painful tumor which was clearly visible and palpable; it lay under Poupart's ligament between the psoas and the pectineus muscles and was of the consistence of bone. On flexion of the leg, however, fluctuation could be detected. The trochanter was in its normal position and movements of the hip-joint were easily made. Adduction, flexion and rotation inward were, however, somewhat limited. The pain extended down to the knee. The corresponding leg was somewhat thinner than the other. This case was diagnosed by a colleague as an impacted fracture of the neck of the femur and the tumor was thought to be a callus formation pressing on the crural nerve and causing pain. There was no shortening of the leg.

Ehrle: A cooper, aged 33, for thirteen years had suffered with pain in the leg and down its inner side. Four months before coming under observation he noticed a tumor situated slightly below Poupart's ligament. This was ovoid in shape and lay under the large vessels. On extension of the leg the tumor became hard. On flexion fluid could be detected. Extension and rotation outward produced pain. By flexion it was clearly seen that the psoas muscle was lifted up. The hip-joint was free.

Herdtmann: The patient had been squeezed between two cars, the chief pressure coming on the left hip. The patient was carefully watched as he was supposed to be a malingerer. On examination, however, a painful swelling of the bursa beneath the tendon of the iliopsoas muscle was found. Flexion of the leg or rotation inward caused much pain in the joint.

Mommsen: This surgeon saw a patient who had an elevated, clearly fluctuating painless tumor which projected from the region of the iliopsoas muscle and passed out beneath Poupart's ligament. It lifted up the femoral artery. On pressure the tumor diminished in size.

Mommsen: The same author reported a case of a man 50 years old who without apparent trauma complained of difficulty in walking on account of a gradually increasing swelling in the right inguinal region. The tumor was as large as two fists and was situated deep in the right iliac fossa. It was firm in consistency and only slightly movable. It was thought to be a sarcoma of the fascia of the hip. At operation its lower pole was found firmly attached to the joint capsule. The cyst walls varied from 3 to 5 mm. in thickness and the failure to detect fluctuation was due to over-distention of the cyst.

Schäfer: The patient, a man coming to Volkmann's clinic, complained of a tumor the size of a child's head situated at the flexion of the thigh and lying under Poupart's ligament. The man had fallen and injured his hip a year and a half before. The tumor projected only slightly above the normal skin surface. It was buried deeply in the muscle of the thigh, was elongate oval and followed the long axis of the psoas muscle. The thigh was markedly flexed. When the leg was extended the tissue was of stony hardness. With extensive flexion some fluctuation could be detected. A second tumor the size of an apple was present at the edge of the gluteus maximus. This tumor also on extension was tense, but on flexion of the hip it became softer. Its contents could be made to disappear and as a result the anterior tumor became more distended. The cystic tumors communicated with one another. The movement of the hip joint was free. The pain radiated from the hip to the knee.

Fricke: This author described a case of a carter who without apparent cause had a tumor in the hip region. It lay over the right trochanter and passed inward under Poupart's ligament and extended downward over the upper third of the thigh. It really formed three tumors. The outer portion was as large as a child's head and markedly distended. The second lay on the inner side of the thigh and the third, the smallest, lay between them. All three fluctuated and the fluid could be pressed from one tumor into the other. The position of the thigh was normal but movement of the hip was impossible on account of the severe pain which was caused especially by flexion and rotation. The tumor itself was not painful on pressure but pain was reflected down to the knee.

Heineke: This author observed a case in the Greifswald clinic in which after a rheumatic inflammation of the hip-joint a prominent and distinctly fluctuating tumor developed. This followed the direction of the iliopsoas muscle from Poupart's ligament downward and raised up the femoral artery. On pressure the tumor diminished but on removal of the pressure the tumor again became prominent. Passive motion of the hip-joint was free and painless. In this case there was accumulation of fluid in the iliac bursa and this communicated with the hip-joint which also contained an excess of fluid.

Wood[6] reported a case in a thin man 28 years old, who two years previously, while convalescing from typhoid fever, had sprained his left hip. Walking was associated with severe pain. Six weeks later he noticed a swelling in this region. There was swelling both in front of and behind the hip and fluctuation was definite. A diagnosis of gluteal abscess was made. The patient, on account of well-marked contraction of the iliopsoas muscle, was unable to extend the leg. The tumor ruptured and there was a spontaneous expulsion of particles of bone as large as beans. The hip-joint was freely movable and not painful. This is one of the very few cases in which the bursa contained foreign bodies.

Couteaud: This patient was a man, aged 31, who was very strong and had done heavy work. Six years previously he had had syphilis. In the left inguinal region and on the inner side of the thigh was a prominent tumor the size of an egg. This was smooth, rounded, painless and could not be made to disappear. The skin over it was freely movable. On examination fluid could be detected in the pelvis and this fluctuation communicated with the tumor. The hip joint was normal. The tumor was punctured and clear citron yellow slightly tenaciou fluid came away. In this case the chief pain was in the regio of the knee.

Since Zuelzer's paper several cases have been recorded. Th most interesting one is that of **Delbet**.[7] This surgeon give very short account of a case in which he diagnosed a cyst tumor of the iliopsoas bursa (a hygroma) before operatio On opening the sac he found three foreign bodies each of whi was the size of a large nut.

DIAGNOSIS

In summing up his article Zuelzer points out that the tumors may be of various sizes and that the swelli

This is probably, however, only a part of the reason for the recurrence of this ulcer. In looking for an explanation of the reappearance of ulcer after so long a time, and for that matter, the explanation of the occurrence of all ulcers, either gastric or duodenal, we cannot forget the very plausible theory of hyperacidity. This theory has been given new standing by a very illuminating article by Paterson,[2] who, indeed, refers to other possible causes of ulcer, but gives hyperacidity the chief rôle. He has very little to say regarding the part that the infections play in the production of ulcer of the stomach, duodenum and jejunum other than that produced by the "toxic" action of hydrochloric acid.

In 1904, at the Milwaukee meeting of the Western Surgical and Gynecological Association, it was my privilege to discuss the relationship of the infections of the gall-bladder to the infections of the stomach and duodenum as expressed in ulcer of either or both of these structures.[3] In that paper, viewed in the light of present knowledge, my present views based on later experiences, were not well expressed; but the practical significance of the observations of that time have not been changed as to the rôle that gall-bladder infections play in the production, not only of the ulcers under consideration in this paper, but of chronic infections of the liver and pancreas as well. A large majority of the cases of gastric and allied ulcers have a history of chronic cholecystitis, and I believe that the recurrence of these ulcers, after a well-performed gastro-enterostomy, is due to the persistence of the chronic infection in the gall-bladder which has not been disturbed or corrected by the anastomosis procedure. If hyperacidity is the cause of the greater number of ulcers, as asserted by Paterson in his excellent article, why is it that only 33 per cent. in a total of 56 of his patients ad a "diminution" of their hyperacidity? Paterson rther maintains that, as a necessary preventive of peracidity following gastro-enterostomy, the anastotic opening should be ample. Failure to make the ening large will account, according to him, for the urrence of the excess of gastric acidity. It is assumed t in the 56 operative cases reported as performed by self, this necessary detail in technic was not overed; yet only one-third of his reported cases showed, ar as followed, a lessened hyperacidity.

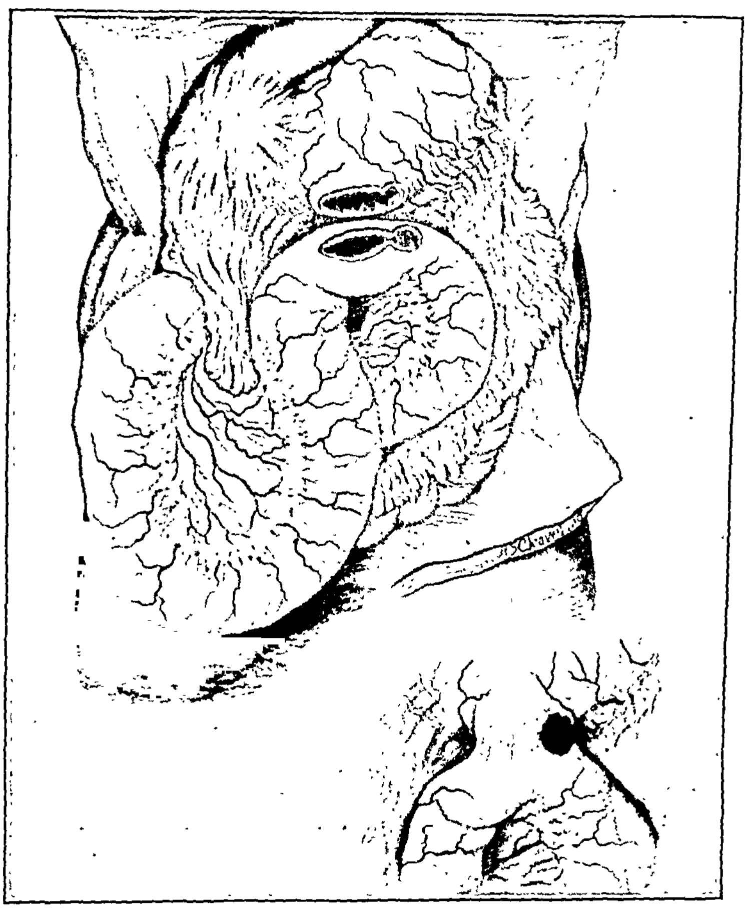

Fig. 2.—Lower right-hand corner, perforating ulcer at site of anterior gastrojejunostomy; above, appearance of former anastomosis on separating jujenum from stomach, also, at right-hand end of dissected anastomosis, perforating ulcer involving both stomach and jejunum.

s the usual picture painted by the symptom-complex astric ulcer and allied conditions in other structures his region not due to another cause than gastric hyperacidity? What were the findings in the case reported here when the abdomen was opened? Adhesions, stasis and infection. Is it strange that an ulcer should appear in close proximity to a reservoir the fluid contents of which have been shown repeatedly to contain not only an abundance of the colon and typhoid bacillus, but also many other forms, as streptococcus and staphylococcus?

The source of the infection of the gall-bladder need not concern us now. But we do need to remember that the typical and characteristic thing about practically every cholecystitis is its chronicity. Acute cholecystitis is a rare condition except when produced by the traumatism of gall-stones. The vast majority of the cases of cholecystitis are chronic because the bile seems to have the power of limiting the virulence of the poisonous organisms which are contained in it. But when this inhibiting influence is lessened, it is often expressed in the form of ulcer of the stomach or duodenum or jejunum. I believe this to be the rational explanation in every case of ulcer in this region of the abdomen, viz., a previous and long-existent cholecystitis. Hyperacidity may play a late part in these infections, but it is not the leading one. Hyperacidity is a common condition without obstruction, dilatation or prolapse. Hyperacidity, when long continued, produces a thickened and tough gastric mucous membrane; in other words, builds a wall against itself. Hyperacidity has no analogue in any other part of the body. Destructive hyperacidity is a chemical dream; while bacteria—some of which do, and others do not develop in the bile—form a focus of infection in the gall-bladder that has back of it all the possibilities spelled by the word infection.

The case which forms the basis for this paper has a known history of cholecystitis for twelve years. The anterior gastro-enterostomy improved the patient's nutrition for eight years to the degree at which it was possible for him to overcome the ill effects of his infection. But the anterior gastro-enterostomy in 1900 did nothing to relieve the chronic gall-bladder infection. The gall-bladder was left buried in adhesions. Because of this peristalsis was inhibited in all these structures, stasis of infected bile was perpetuated, and the chronic infection remained as a future menace to the stomach and the first portion of the small intestine. This menace of infection again became a certainty when it expressed itself finally by a hemorrhage in March of last year.

As I pointed out in my previous paper,[3] chronic cholecystitis may also be the "cause of cirrhosis of the liver in an individual otherwise free from the usual history

Percy, J. F.: The Practical Significance of Certain Common oms in the Upper Abdomen, THE JOURNAL A. M. A., 1905, 3.

that precedes the average case of this disease, viz., chronic alcoholism," and I gave the history of three cases which bear out my statements. These are the cases of cholecystitis in which the liver and pancreas bear the brunt of the infection, and not the stomach or small intestine. To quote again from that paper:

> As long as we have ulcer in the stomach or duodenum, or an infected gall-bladder, to furnish a long-continued infection through the lymphatics to the liver and pancreas, we are sure to have occasionally a patient who will die following operative procedures in the upper abdomen, regardless of the skill with which such operative procedures are conceived, or by whom carried out.

Is it necessary for me to add that infections of the liver and pancreas due to a chronic cholecystitis furnish a larger mortality, with or without operation, than do the infections in this region which result in ulcer?

In closing, permit me to urge that every gastro-enterostomy for ulcer, or its sequelæ, have combined with it drainage of the gall-bladder, unless the operator fears that the additional traumatism may add too much of additional danger to the outcome for the patient. This was true in the case which I have reported above. At the present time, ten months following the operation, the patient is in perfect condition in every way. Not only is this true as to normal gastric acidity, but weight, hemoglobin and strength are also normal. But the patient still has his chronic cholecystitis.

The cases of ulcer herein referred to in which cholecystitis is not present are so few in number that they may almost be ignored. I believe that cholecystotomy is practically always indicated because their successful and permanent cure can only thus be secured.

A METHOD OF TREATING MANDIBULAR FRACTURES *

ROBERT T. OLIVER, D.D.S.
Examining and Supervising Dental Surgeon, U. S. Army
WEST POINT, N. Y.

Modern surgical science teaches that the essential requirements for successful treatment of mandibular fractures are readjustment of fragments, restoration of normal dento-articular plane, fixation, immobilization, rest, nourishment and aseptic hygiene.

Of these cardinal factors there is little doubt but that fixation and immobilization have always proved the greatest problems. Surgical history is replete with various and many methods for the accomplishment of these ends, and a review of the literature on this subject shows that during the past half century, or since the Civil War, there have been two general schemes in vogue, each with numerous modifications, namely, the application of external support through medium of mento-mandibular splints, with occipitomental counter-pressure and the application of internal support through adaptation of interdental splints, with occipitomental counter-pressure.

Generally speaking, the medical profession has advocated the first, and the dental profession, from which it emanated, has championed the second method.

In addition to these, there has been frequent recourse to processes of wiring and in recent years to a natural development of these processes, the adjustable fracture bands and traction-bars.

So many well-founded objections have been raised against the use of external splints, mainly on account of their general inefficiency in maintaining adjustment of contour and articular plane, that the method has become practically obsolete. The introduction of interdental splints marks an epoch in the history of maxillary fractures of which dentistry may well be proud. It gave at once such assurances of holding the adjustment and maintaining the articular plane, thus restoring normal function and preventing deformity, that it rapidly sprang into prominence and custom. But the indiscriminate use of these appliances without due consideration of the individual requirements of each case, or of the kind, style or application to the cases presenting, combined with such objections as uncleanliness, strain and soreness of muscles from jaws being kept open, the length of time required before appliance could be constructed and the discomfort to the patient in securing proper impressions, have produced a marked decrease in their popularity.

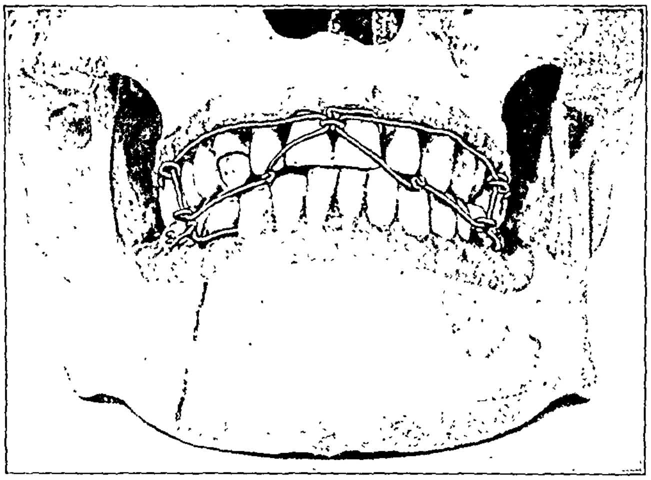

Fig. 1.—Front view, showing detail of wiring by anchor loop and traction wire method.

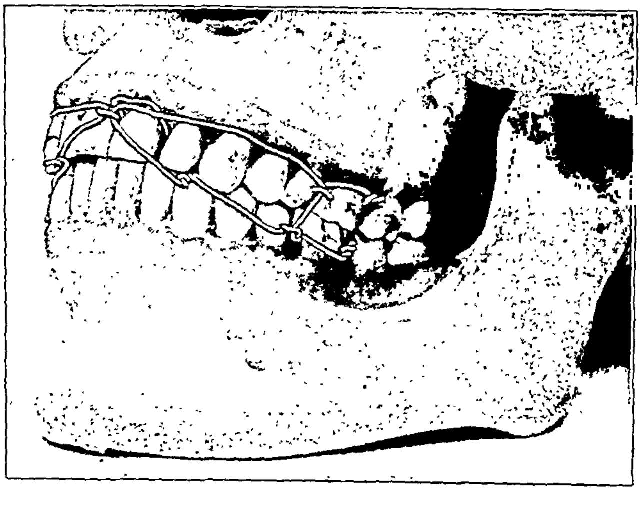

Fig. 2.—Left lateral view of same subject.

The objections to the usual methods of wiring have been due to faulty modes of application and to the kind, size and strength of wire employed. In a great majority of cases the ordinary silver suture wire, 26 to 30 gauge, has been used. This always stretches under stress, becomes loosened from around the teeth, releasing the traction necessary to fixation and is often forced into

---

* Read in the Section on Stomatology of the American Medical Association, at the Sixtieth Annual Session, held at Atlantic City, June, 1909.

the soft tissues, producing distress to the patient and the usual consequences of irritation and inflammation.

The adjustable fracture band and traction-bar method has proved very efficient. Its disadvantages accrue from the numerous appliances required, which tend to hinder its general applicability.

Being firmly convinced that a process of wiring presented the simplest, easiest, quickest and surest method of treating these cases, I began a series of experiments some years ago, with a view to the improvement of its technic and the development of a standard method whereby rigid fixation and absolute freedom from mobility could be obtained. It was recognized early that much heavier wire, less ductile than silver, would be necessary, that the old figure-of-eight plaiting of wire across the line of fracture must be discontinued, and that some plan to prevent lateral mobility of jaws must be devised.

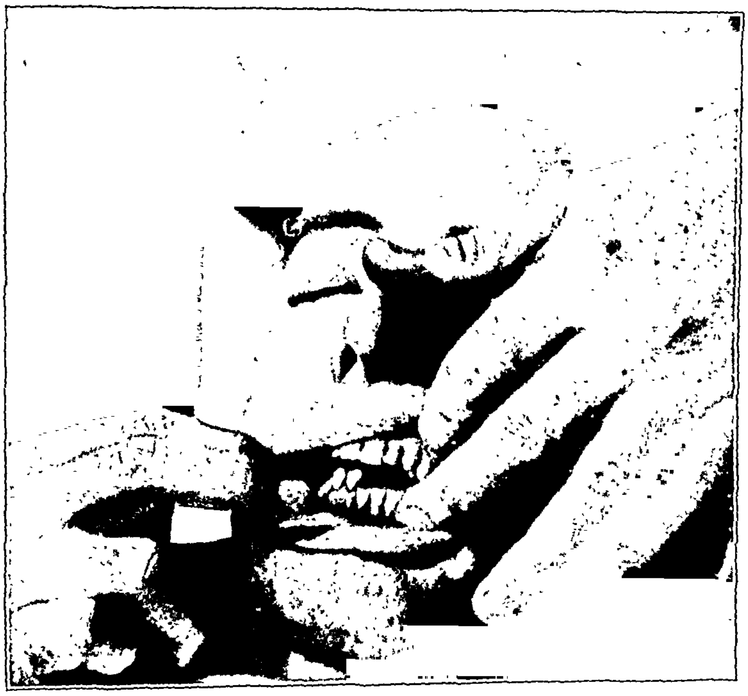

Fig. 3.—Cadet ———, U. S. M. A. Compound fracture, transverse through socket of right lateral. Showing deformity one hour after occurrence.

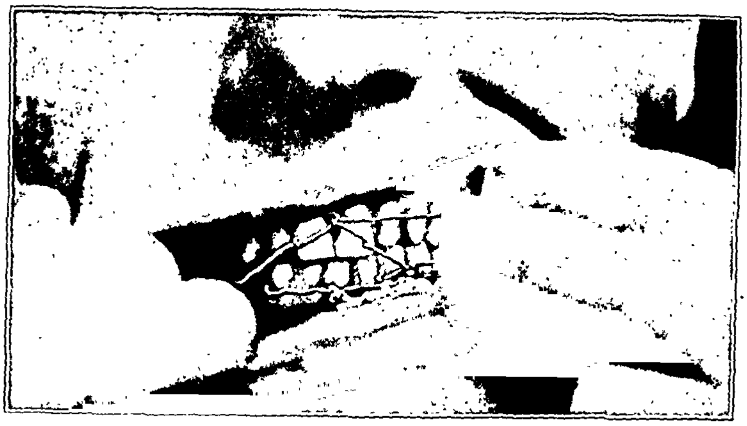

Fig. 4.—Same patient, front view, with jaw wired.

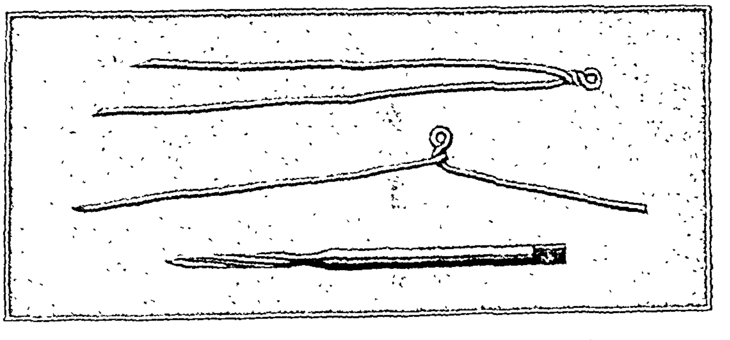

Fig. 5.—Median and lateral anchor loops and Peeso's reamer.

With these objects in view, various schemes were tried, with varying success, until the following method was adopted in 1903. Since then it has been used exclusively, with such splendid success that not one case of failure to unite, deformity, deflected articular plane or impaired function has resulted. For purpose of illustrating the method let us suppose a case with simple fracture, slightly transverse through socket (distally) of right first bicuspid and mental foramen, slight deformity, articular plane deranged, long anterior fragment drooping somewhat and short posterior fragment drawn slightly upward and inward—the typical picture. The mouth is first thoroughly cleansed with hot antiseptic wash and swabs, the location and extent of fracture determined and the fragments adjusted and articular plane restored. Then a piece of soft drawn copper wire, about 4 inches long, previously annealed and sharpened at each end, is inserted from without inward between the right lateral and cuspid, is pulled through about half its length, burnished lingually to cuspid and then inserted from within outward between cuspid and first bicuspid, pulled through buccally again, where it is held. The other end is now brought back and inserted at the latter interproximal space, pulled through taut, burnished lingually to first and second bicuspid, carried back across line of fracture, inserted from within outward between first molar and second bicuspid, pulled through buccally again, brought forward taut across line of fracture and twisted with remaining end at a point opposite an interproximal space. The adjustment of contour and articular plane is now verified; after which the ends are tightly twisted, bringing firm traction through axis of each fragment across line of fracture which temporarily will hold the parts in their exact position. The twisted ends are clipped off, leaving a stub about an eighth of an inch long; this stub is turned upward and inward, entering the interproximal space far enough to prevent it from injuring any soft tissues with which it may come in contact. Immobilization is next accomplished by wiring lower to upper teeth, while occupying normal occlusion. This is done by the following original method, which insures against the possibility of *any* mobility, either lateral or perpendicular: First, an anchor loop is made by taking a six-inch piece of annealed soft-drawn copper wire, 20 gauge (B. & S.), bending it in the middle around a small-sized mandrel about one-thirty-second of an inch in diameter, and twisting tight by one full turn with flat-nose pliers (the twist may be strengthened by "tacking" together with a small bit of hard solder). The two long ends are now straightened out and placed parallel to one another, one end being snipped off one-fourth of an inch shorter and both ends pointed. They are now inserted from without inward, between the two superior central incisors, pulled through taut until loop rests, horizontally, firm against both teeth at the mesocervical border. Each end is now carried laterally from median line, burnished, respectively, to lingual surface of each central, and inserted from within outward between its respective central and lateral, pulled through firmly, brought forward to median line, above loop, and twisted tightly together, clipping off and turning stub into interproximal space as before noted. This forms a solid, permanently fixed, median anchor loop from which counter-traction may be had from each lateral half of mandible for support and the prevention of lateral mobility. Four pieces of the same wire, about 3 inches long, are in turn bent around the mandrel as before cited, forming the loop about one-third distance from one end, and the long end sharpened. These lateral anchor loops are placed around solid teeth, one on each side, usually first molars or second bicuspids, in both upper and lower jaws, and serve as anchorages for the traction wires, one for each side. These traction wires, threaded through all the loops commencing with median, then superior lateral, then inferior lateral and finally twisted with outer end midway between inferior lateral and median loop, exert a firm and constant pressure between upper and lower jaws and at the same time maintain counter-traction laterally. The twist is clipped short and may be turned upward under upper teeth. The lateral loops are positioned by inserting long ends into mesoproximal spaces of the respective teeth selected, pulled through taut until loop rests horizontally against cervicoproximal border, then carried backward, burnished to lingual surface, inserted from within outward at distoproximal space, pulled through firmly and twisted to outer end as near the latter proximal space as possible in order that the increased size of twist, being too large to pull back through space, will prevent the anchorage loop turning under stress of subsequent traction and also that the twist may be clipped off and turned into the space as above shown. The traction wires are about 7 inches long, of same material, and should be annealed before being used. Care should be exercised to keep each one perfectly straight between loops and pulled taut in passing through each loop. When properly placed there will be produced a triangular geometrical figure with its first "stretch" a long horizontal line from median to superior lateral loop, a short perpendicular line from superior to inferior lateral loop and a long slanting diagonal line from inferior lateral to median loop, in which the twist has been made. With these heavy traction wires firmly fastened from each side of jaw with teeth in normal contact, there is little likelihood of any kind of motion between either the fragments or the jaws. Thus we have absolute fixation and immobilization exemplified in one operation of two stages.

It usually becomes necessary to tighten the wires after the second day. This is readily accomplished by simply turning an angle with narrow-beaked flat-nose pliers in each long stretch of each traction wire, thus taking up the slack which may be caused by loosened lateral anchorages, from inflammatory processes or by the stress of traction on the respective teeth. This tightening can be done every few days, as required, until the angle thus formed may be turned so far as to produce the letter Z. It seldom reaches this point, however, if care is exercised in keeping wires straight between loops and taut at each, when they are first applied.

Should a wire break or become ineffective from being stretched, a very firm occipitomental bandage is applied and both traction wires cut and removed. The anchorage loops are now tightened and new traction wires applied as before.

In cases in which the teeth are irregular or crowded too close together to permit the insertion of wires between them, an opening is made through soft tissues and alveolar process about one-eighth of an inch below its superior border and between the roots of teeth. This is done by quickly forcing a rapidly revolving Peeso reamer through at the point desired, and is usually accompanied by very little pain and slight hemorrhage. The subsequent tight pressure of wires on these soft tissues requires no other attention than the maintenance of cleanliness, as the position of wire is accommodated and the pain is negligible. In severe cases, in which a general anesthetic is required, the whole operation above outlined should be completed except the insertion of traction wires. These should not be introduced until the next day, after the fear of nausea or vomiting has passed. Even then it is well to leave a small pair of wire-cutting shears with the attendant, with instructions how and when to use them should such interference be necessary.

With this means of securing durable fixation and thorough immobilization, the physiologic function of reuniting takes place readily and rapidly.

The patient is fed on liquid diet, consisting of broth, thin gruel, milk, custards, etc., every two hours, with egg-nog three times a day, taking it through a rubber tube which may enter the mouth either through an existing vacuity or by being forced back through the post-dental space.

The patient rarely experiences pain after forty-eight hours, and if the usual instructions in regard to rest, nourishment and oral hygiene are followed the wires may be removed during the latter part of the third week, a firm occipitomental bandage being substituted for them for several days following. In removing the appliances, the traction wires are first cut and slipped out, leaving all anchorage loops *in situ* for subsequent use should it become necessary, for any reason, to fasten up the jaws again. When everything is finally removed the teeth, mouth, tongue and gums should be thoroughly cleansed and the patient instructed in the discriminate use of the jaw for a period of several weeks.

With some nervous patients having a hysterical tendency, it is good practice to supplement this wiring process by adjusting one of the many forms of occipitomental bandages—this as much for the psychic effect on the patient as for any mechanical assistance rendered.

Hot antiseptic mouth-washes should be used five or six times daily and all the loops, wires, teeth, gums and mucous surfaces thoroughly swabbed with a 50 per cent. solution of hydrogen dioxid at least once a day, followed by the hot antiseptic solution.

ABSTRACT OF DISCUSSION

Dr. M. I. Schamberg, New York: In treatment of fractures of the jaw, we are not always able to employ anything which depends on the occlusion of the teeth, because in some cases the teeth are absent, but when there are a sufficient number of teeth to use one jaw to splint the other, I think it is the ideal method of treatment. I do not altogether agree with Dr. Oliver that so elaborate a method of wiring is essential, as I have achieved good results from the use of very simple methods. That is, taking ordinary brass wire, passing it between the teeth, and bringing it up taut as for the retention of a rubber dam. I do this in several parts of the mouth, thus supporting the lower jaw. I frequently find it necessary to run these wires in various directions to maintain proper traction. In dealing with these fractures, owing to the fact that many of them reach us after the patient has gone through other hands and reduction has not been complete or has not been maintained, I have found it necessary to pass the wire through the inter-dental space between the bicuspid of one side and create traction forward by means of this by an assistant while the jaws are brought into position. I believe that the method outlined by Dr. Oliver is a valuable one, particularly because it gives the part absolute physiologic rest. It seems to me unreasonable to expect good results with the use of splints which permit the patient to masticate during repair. A patient can live for many weeks on liquid nourishment.

Dr. J. E. Power, Providence, R. I.: I agree with Dr. Schamberg that the more simpler methods of using wire have given excellent results. I cannot, however, agree with either Dr. Schamberg or Dr. Oliver in the recommendation of any appliance that will cause absolute fixation of the upper and lower jaws. I believe that it is unfair to incapacitate the patient if the fracture can be treated in any other way. Dr. Oliver describes in his paper the method which I have used in what is known as "first aid to the injured"—not, however, with the exacting technic or elaboration which he has demonstrated here. In fractures such as Dr. Oliver has described I first get an impression of both the upper and lower jaws, then I make plaster models, sawing the model through the lines corresponding to the lines of fracture. I then reconstruct the model, first getting normal occlusion, with the opposite jaw. A die and counter die are then made and a metallic splint is swagged (preferably of aluminum) to fit over the teeth on the reconstructed model. The time consumed is not much more than one hour, and the operator may have the prosthetic assistant attend to the making of the splint. If the model has been properly reconstructed according to recognized anatomic lines, the splint can be easily adjusted. Its advantage is that the appliance does not incapacitate the individual in any way, and it does not interfere with the natural method of feeding. Three or four hours after the splint is adjusted the patient can go on with his regular work, without any inconvenience. Dr. Schamberg places great stress on physiologic rest.* If the cardinal principle of surgery is rest, then we bring it about in the case of fracture, by fixation. If there is a fracture through the bicuspid region such as the one described by Dr. Oliver, and the fragments are brought together and held in position by a metallic splint, the parts are given physiologic rest. Physiologic rest does not mean absolute rest of the whole oral cavity and its appendages, if only one of the bones is fractured. This is demonstrated in the general practice of surgery. If a fractured limb is subjected to absolute rest for a long period, there will be muscular atrophy; this is guarded against by the general surgeon through the medium of massage of the parts involved. If this great law of use and disuse applies to a limb, it is reasonable to believe that other parts of the body will be likewise affected. I claim, therefore, that it is an advantage to overcome this tendency to muscular atrophy, by allowing the patient to use his jaws and by holding the fragments in position with the splint which I have described, whereby the proper amount of physiologic rest is applied to the proper area. I think that absolute rest of the jaw which is not affected, as well as of the affected one in uniting them by any method which will impair their normal action is a disadvantage both to the process of repair and to the comfort of the patient.

Dr. George V. I. Brown, Milwaukee: There are many conditions under which we have to care for fracture of the jaw; therefore, we need many appliances and different forms of treatment. Dr. Oliver offers his method as one kind of treatment and would, no doubt, make distinction in the treatment of other cases. He has given a method of wiring the jaws which is undoubtedly one that would give absolute immobility and is free from the disadvantage of silver wire, which I think a very important improvement. I abandoned silver wire some time ago, because it is not trustworthy. There are a few principles in the treatment of fracture which I try to keep in mind. One is, I never fix the jaws immovably unless I know that I am obliged to. There are many reasons for this: one Dr. Oliver himself called attention to—in case of vomiting this is sometimes a very serious condition.

Dr. M. L. Rhein, New York: What other objections to immobilization have you?

Dr. Brown: None to immobilization of the fractured bone, but much to fastening the two jaws immovably in contact with each other. One is vomiting. Again there may be septic infection. If it be a comminuted fracture there are apt to be sequestra of bone coming away, and in these, as with other cases, it is important to be able to get into the mouth and keep it clean. Again, there is the question of food and nourishment. Or, there may be other injuries which make jaw fixation inadvisable.

Dr. M. L. Rhein, New York: I agree with Dr. Brown on presentation of Dr. Oliver's improved method, and I want to emphasize strongly one of Dr. Brown's points, and that is the ultimate method of immobilization. It is often important to delay to some extent in the manner described. If there are any sequestra of bone in the fracture it is important that they should be thoroughly diagnosed as early as possible. I have a number of such cases that have slipped by the hands of surgeons without such a diagnosis having been made, necessitating a subsequent operation on the mandible. At present, with the aid of the *x*-ray, it seems impossible to make such an error, and I think this is another instance in which the value of the radiograph when it is obtainable is of great importance in determining the absolute line of fracture, as it will also readily show whether or not there are any comminuted pieces of bone necessitating operative interference before any form of immobilization is permanently used.

Dr. W. C. Fisher, New York: I think that there is one class of cases in which Dr. Oliver's method is very applicable; those that might be termed vicious. Patients who are in the habit of taking intoxicants, sometimes become very unmanageable and tear off the splints, and in such cases this method would be most desirable. I recall the case of a patient with a fractured mandible, acquired in a drunken row. After having an interdental splint in place for about a week, he became so crazy for a drink he went to a saloon and tore off the splint in order to drink. It was necessary to wire his jaw. Some method such as described by Dr. Oliver would be far better than wiring the bone.

Dr. M. I. Schamberg, New York: We have overlooked the fact that this form of treatment is applicable to all forms of fracture at or above the angle of the jaw to much better advantage than any splint which enters the mouth. Anything which tends to distend the mouth or which depends on the adjustment of a splint is not serviceable in cases of fracture at the angle or above the angle. When the fracture is at the neck or about the head of the condyle I believe that the wires should be so placed that there can be passive motion at proper intervals.

Dr. Stewart L. McCurdy, Pittsburg, Pa.: Without referring particularly to the method, it appears to me to conform in some respects to that suggested by Angle, except that he applies bands instead of wires in order to secure replacement of bones. I desire to make two points. I use iron wire. I have taken *x*-ray photographs of these iron sutures year after year during the last eight years, and find that the iron eventually becomes disintegrated and entirely disappears, so that it is harmless so far as its action on the tissues is concerned. As to the adjustment of the bone itself, being a general surgeon, I use the means at my command, just as the dentist uses the means at his command. I use the through-and-through method of wiring in all these cases. Several years ago I reported 18 or 20 cases in which this method had been used.

Dr. R. T. Oliver, West Point, N. Y.: While I do not claim that this method of treating fractures will successfully meet the requirements in every case, yet I think its application in general will come nearer being the correct treatment for more cases of fractured jaws than any other one method. Neither this method nor any other can be hailed as the universal one for all classes of cases. I merely attempt to portray a method of treating mandibular fractures, in which I bring out an original scheme of securing absolute immobilization by a process of wiring. I prefer the word adjustment instead of reduction in speaking of fractures of the jaw. We reduce luxations but really do not reduce fractures. I am not trying to change the nomenclature of surgery but this is the way it appears to me. Some one suggested that the question of occlusion or the articular plane could be dispensed with, in favor of some other things of greater importance. I want to say most emphatically that the most important thing in treating jaw fractures is to restore occlusion and reproduce the function of mastication. Even deformity must take second place to impaired function. This is especially true in the army, where the soldier's physical fitness and military efficiency is to a great extent dependent on his ability to masticate his food thoroughly in preparation for the process of digestion and assimilation, in order that his full physiological powers may be maintained. His personal appearance counts for naught. Of course there are a few cases in which impaired functions and deformity cannot be restored together, but if it comes to a question of one or the other, it certainly is for the best interest of the patient that his ability to masticate receives attention first. I believe that both anatomic and physiologic rest are essential in these cases. The earlier we can operate and get the end of the fragments together, thus facilitating the initial processes of callus formation, the quicker and less troublesome will be the cure.

The remarks of Dr. Schamberg in regard to the continuation of the old method of wiring, are rather surprising. I presume he refers to the method of using small guage silver wire by the figure-of-eight method or some modification of it. I have used and seen it used by able surgeons, many times, and its reliability in these cases is always questionable. The failures to maintain fixation and immobilization are not through technic, but through fault of the wire itself; generally it is too small and too ductile to withstand the stress of tension. In the methods spoken of by Dr. McCurdy, I believe there will be extensive oxidation of the wire used, with more or less permanent stain of the tissues and a marked metallic taste complained of by the patient.

The method I have described was developed during my service in the Philippine Islands and is the result of a gradual evolution of experimental wiring in these cases. During the early days of foreign service, before the department furnished adequate equipment, many makeshifts had to be utilized. On one occasion, I was called hurriedly to one of the reserve hospitals in Manila to attend a case of multiple compound fracture of the mandible. The man had been thrown and stepped on by his horse and was in such pain, with profuse hemorrhage, that an immediate operation was necessary. Previously I had always used silver wire—the Fleurs sutures—but there were none available at that hospital and as an expedient an orderly was sent with a note to a nearby Signal Corps station requesting some 20 guage wire. He returned with a big roll of copper, field telephone wire, from which I burned the insulation. After annealing and sterilizing, this was used and proved so efficacious and superior to the silver wire in being tougher, less ductile and possessing greater stability of the twists, that it has been used ever since.

Some one referred to the use of modeling compound. This material has proved useful in emergencies, and first-aid treatment, but I do not wish to discuss its possibilities at present as it will be covered in another article now under way.

THE FUNCTIONS OF A UNIVERSITY MEDICAL SCHOOL *

VICTOR C. VAUGHAN, M.D.
Dean of the University of Michigan College of Medicine and a Member of the Council on Medical Education of the American Medical Association
ANN ARBOR, MICH.

The functions of a university medical school are many, varied and important. Some pertain to the school itself, some more particularly concern the university as a whole, while others are chiefly employed with affairs that lie quite outside of the university. All are correlated, however, and more or less mutually dependent. It is my purpose in writing this paper to outline briefly what a university medical school should be and some of the things that it should do.

Without men of proper intellectual and temperamental equipment no great work can be accomplished; consequently the school must be developed and directed by a faculty, the members of which have both the inclination and the ability to move forward in the right direction. A university professor should be possessed of a broad fundamental training, including both the humanities and the sciences, and on this as a foundation he should develop expert knowledge of the special subject in which he is to instruct others. His training should be both general and specialized. The former gives him a broad outlook and causes him to realize that all knowledge is correlated, while the latter is essential to every one who has any claim to leadership. Appreciation of productive scholarship in American university medical schools is growing, and the research now being done in some of the best of these schools begins to compare favorably with that of European institutions. However, it still remains difficult for university presidents and boards of control to distinguish between pseudoscholarship and real scholarship in the selection of professors, and appointment to such a position in this country is no guarantee that the appointee has either culture or learning. In this particular the university medical schools are faring better than other university schools, because in the former nominations for new professorships and to fill vacancies have been generally left to the faculty. Some universities seem to feel that they are doing their full duty if they fill one or two chairs with research men. As a friend of mine has expressed it, they act as if the possession of a silk hat is the sole requirement of a well-dressed man. The demand for productive scholarship in university medical schools should be more fully extended to the clinical subjects than has been evident up to the present time. It should be expected of each professor not only that he master his specialty, but that he labor to make worthy contributions to it. This it is that has made German medical science so pre-eminent. The old fallacy that a research man is only a dreamer, without practical knowledge, and consequently not a successful teacher, is slowly, too slowly, fading away in this country. The deepest inspiration for work comes only to the one who can occasionally drink from the head fountain of knowledge, and opportunity for research is as essential to the teacher of any branch of medicine as is air to the support of life. The university professor who does not devote a considerable portion of his time to honest and earnest endeavor to extend the bounds of knowledge is unworthy of his position and should be replaced.

The evolution of the combined course for the medical student has been an important and wise move. That it has its deficiencies is true, but there is always the opportunity for improvement. I would be pleased were it to provide for a more extended and thorough knowledge of the classics. The small requirement in Latin is not wholly worthless, but it is altogether inadequate, and the absence of any requirement in Greek is unfortunate. It is true that the medical student learns something of Greek in every subject even without knowledge of the alphabet of that language, but he too often only sees through a glass dimly, while two years of proper preparation in Greek would enable him to discern more clearly the significance of the terms that he employs daily. However, even with its deficiencies, the combined course gives at least the opportunity for the medical student to start on his professional studies from a point of great advantage. The humanities and the sciences, in their fundamental principles at least, afford him a sure and safe foundation on which he can proceed to erect the professional superstructure. The principles of chemistry, physics and biology which he has acquired are the foundation stones on which he is to build. The modern languages place within his reach most needful help. His mathematical studies give an idea of the necessity of exactness and fitness of proportion, and, as he builds, his general studies, history, literature, political economy, psychology, etc., supply the windows from

---

* Read before the Sixth Annual Conference of the Council on Medical Education of the American Medical Association, Chicago, Feb. 28, 1910.

which he can look out over the wide realm of human experience. Surely, our successors in medicine, in the mass, should add much to the science and advance the practice of our profession.

Next to the selection of a proper faculty and provision for well-prepared students comes the equipment of the medical school. To this important subject I can devote only a few sentences. Fortunately the Council on Medical Education has formulated a somewhat detailed statement on this subject, and to this I refer those who wish to investigate this matter. More than thirty years in a relatively small school and observation of others, both small and large, good and bad, lead me to say in general terms that the primary cost of a suitable building and its proper equipment for a school with an entering class of from fifty to one hundred students cannot now be provided for with less than one-half million of dollars ($500,000). It should be understood that this does not include hospital facilities, which would multiply the above figures by not less than four. Moreover, it pro-
des laboratories and class rooms of only the plainest
l, and it makes no provision for any equipment above
which is absolutely essential to high-grade work.
r support of such an institution, again apart
the hospital, demands nearly two hundred thousand dollars ($200,000). With average tuition and laboratory fees the annual income of a medical school should be multiplied by at least three, better by four, in order to balance the necessary expenditures. As I have elsewhere pointed out, a medical education worthy of the name is the most expensive professional training offered in this country. The time has passed when a group of physicians can combine and launch a medical school and give anything like proper training to its students. The medical school of to-day must have behind it private endowment or state aid. Even universities should not attempt to establish medical schools unless they can afford the expenditures mentioned above, and provide adequate hospital facilities besides. To maintain a medical school inadequately is, in a certain and large sense, criminal, because it means the sending out of unqualified practitioners, and this means danger to the health and life of those whom they serve. I have elsewhere
attempted to show that the state do serves
its own interest in supplying the bes tion.

Of the functions of the medical uite
within itself, I shall refer to only the

lessness in method are not tolerable in either the teacher or the student of medicine.

Of the additional functions, some, as I have stated, lie within and some without the university. Of the former I will speak first. There are many advantages in the close association of the college and the different professional schools, which together constitute our larger universities. The collegiate department should serve for preparation for the professional schools, and the smaller colleges should also attempt to perform this function. In medicine at least the advances of the past few years have been so great that the secondary schools no longer suffice to fit the student for his professional studies. The Association of American Universities has done well in its definitions of a college and a university school. The college is regarded in these definitions as the preparatory department for the university schools which collectively constitute the university. An important function of the university medical school is to command the respect of the faculties and students of the college and other professional schools by the thoroughness of its instruction and the extent and value of its productive scholarship. The medical school should be a leader in both culture and knowledge. The uneducated, narrow man, ungrammatical in speech and of limited intellectual vision, whatever be his skill in his specialty, does not make a desirable professor in a university medical school. Scientific medicine deserves and should win the respect of the learned. In some things the medical man should be the leader.

Within the past decade a movement, such as the world has never before known, founded on medical research and discoveries, has been inaugurated and holds within itself the promise of the greatest good to the race. I refer to the realization, which is just beginning to dawn on the most enlightened men, that disease is the heaviest burden that humanity carries in its slow and
weary es the mire of superstition on its way
to the u uman bett t, and that disease is,

slight abnormalities of the heart. Men who are to become sanitary engineers are graduated without training in the bacteriologic examination of drinking-water. Those who are to become potent factors in the framing and execution of our laws go from their universities in ignorance of a nation's best asset, public health.

Please do not understand that I am saying these things in a spirit of captious criticism. I might have made these statements much stronger and still not overstep the truth. I have called attention in this mild way to these defects in order to point out that it is one of the functions of the university medical school to remedy them. Medical men in these schools should give lectures and demonstrations to the students of other departments on preventive medicine. The consequences of venereal diseases should be described without magnification, and with rational advice to the unfortunate. The nature of infection and the avenues through which it is spread should be discussed. Were I not a professor of hygiene I should say that every university student should have instruction in this branch and should submit to a most thorough physical examination twice a year and should he be found to carry any infection dangerous to others, whether it be pulmonary or venereal, he should be compelled to conform to just rules and regulations. I am aware that some effort is being made in these directions in universities, and the purpose of these remarks is to encourage it, for the need is great and the result will amply repay the service.

The academic professor has somewhat reluctantly learned to recognize that scientific medicine offers a legitimate field for research, and graduate students are now permitted to work in our laboratories. We should return this compliment and urge on our students a further and broader acquaintance with psychology, history and literature, for I would not imply that the medical school is the only department of the university that may confer favors.

Only a few days ago a professor of history applied to me for a medical man who might help him in the interpretation of documents bearing on a certain period of English history. It is good for all to change the viewpoint occasionally, for by so doing we extend the field of vision and gain a clearer perception. Interchanges of opinion among men of diverse callings should be mutually beneficial.

Medicine is taking its place among the exact sciences, and in doing so it discards the mantle of metaphysical speculation which it once wore. It consists of facts gathered from the various sciences that may be used in the prevention or cure of disease. It is no longer divided into schools founded on speculative dogma, or on theories evolved from the inner consciousness. Its triumphs are won only by patient toil in the laboratory and by exact observation at the bedside. It tolerates no *ipse dixit* and acknowledges no authority save that of scientific demonstration. The world has never been in greater need of its help than at the present time. The purpose of medicine is the evolution of the better man, free from disease, both inherited and acquired. In material rewards medicine benefits most abundantly those who do not practice it. In both prevention and cure it serves not only the individual, but his neighbor as well. Its future in this country is largely in the keeping of our universities and the administrative boards of these institutions have a duty to perform which they cannot shirk without detriment to the future welfare of the people.

Of the functions of the university medical school that lie outside the university I have time to mention only two, and with these I must content myself with scarcely more than mention. The faculty should take an active part in the education of the public in preventive medicine. This can be accomplished by popular scientific lectures, given orally and disseminated in print. It should support state, municipal and rural boards of health, be ready with the best advice concerning the securing of wholesome drinking-water, the most scientific methods of disinfection and the administration of wise pure food laws. In the second place, the laboratories and clinics of the school should be open to all legally qualified practitioners of medicine, who should feel that they are welcome to turn to these sources of exact information whenever they desire to acquaint themselves more thoroughly with the advances made in their profession.

SOME NEW FEATURES IN THE CLASS METHOD OF TREATING TUBERCULOSIS *

MYER SOLIS COHEN, A.B., M.D.
Consulting Physician to the Home for Consumptives, Chestnut Hill; Visiting Physician to the Philadelphia Jewish Sanatorium, Eagleville
PHILADELPHIA

THE CLASS METHOD OF TREATMENT

The class method of treating tuberculosis has grown in popularity since its inauguration in Boston by Dr. Joseph H. Pratt on July 1, 1904. There are now many tuberculosis classes in different parts of the United States, especially throughout the East. All present certain features in common.

Each patient keeps in a special book a daily record of his temperature, pulse, food, hours in the open air, etc. Special books have been printed for this purpose, costing five or ten cents apiece, although any small note-book will answer.

The patients are visited in their homes by a paid nurse or social worker or by a volunteer friendly visitor. The visitor inspects the house, shows the patient how to live, and sees that he carries out the details of the treatment. The financial condition of the patient and of his family is investigated. In some instances direct assistance is given from the class funds (when such exist), in others appeal is made to charitable organizations, fraternal societies, religious bodies and benevolent individuals. A few classes have no visitors.

A fund is frequently provided for furnishing tents, cots, reclining-chairs, blankets, record-books, thermometers, sputum-boxes, paper napkins, paper bags, milk, eggs, olive-oil, car-fares, etc., and for erecting platforms, balconies, awnings and screens, and to meet the expenses of moving the patient to a more suitable house. This money may be supplied by a church or by a hospital or by private individuals. The expenses of the Emmanuel Church Class from July 1, 1904, to May 1, 1907, were about $2,000. Many classes, however, have no such fund, the patients themselves having to furnish the things they need or being supplied through some outside charitable agency.

Once a week the patients assemble for examination, instruction and encouragement. The physician in charge sees each patient in turn. Sometimes he also talks to the assembled class and endeavors to stimulate a spirit of emulation among the patients, posting on a blackboard the greatest gains in weight and the greatest number of hours spent out of doors. In some classes the members sit by themselves for about half an hour before the physician arrives and compare notes.

---

* Read at a meeting of the Philadelphia County Medical Society, Dec. 22, 1909.

This weekly meeting is the distinctive feature of the class treatment. Its success depends largely on the personality of the physician in charge. In many instances, however, it does not differ from the ordinary dispensary hour, owing to the difficulty experienced by many class leaders in maintaining their enthusiasm while giving the same talk to the same patients for the eighth or tenth time, and in stimulating rivalry among patients who, after several months, desire to get well rather than to excel in detail.

The method of treatment adopted in the various classes depends largely on the individual views of the physician in charge and the conditions to be met. Dr. Pratt, of Boston, requires all his patients to sleep in the open air. Owing to the absence of yards, verandas or arch-ways in New York City, none of Dr. Niles' class slept out of doors. Some physicians demand of the members absolute rest; others permit graduated exercise and labor. Milk forms the basis of the diet in one class, three substantial meals in another. Drugs are little used in many classes. Some employ hydrotherapy; others do not. The same is true of the use of tuberculin.

THE UNIVERSITY OF PENNSYLVANIA TUBERCULOSIS CLASS

The tuberculosis class of the Medical Dispensary of the Hospital of the University of Pennsylvania has been in existence for over two years. Formed originally of the tuberculosis patients from my room in the medical dispensary it now receives from all the rooms in this dispensary, through the social service, tuberculous patients who are considered suitable for class treatment. There is no fund at the disposal of this class; nor is there any expense connected with it: it costs the University Hospital nothing.

The patients are visited at intervals by the social worker of the hospital or by volunteer friendly visitors. The social worker investigates the financial condition of each patient and, where necessary, solicits aid from charitable organizations or from the patient's relatives, employer, pastor or church. The visitor furnishes the class instructor with a written report of the home conditions and reports from time to time whether the instructions are being carried out.

The patients provide themselves with clinical thermometers, sputum-cups, paper napkins and paper bags, which they can obtain from the hospital at wholesale cost price. In a small note-book each keeps a daily record of the amount and character of the food taken, the number of hours spent in the open air, and in sleep, rest, exercise and work, the number of bowel movements, the amount and character of the cough and expectoration, the morning and evening pulse and temperature, etc.

The home conditions are modified according to the possibilities of the house and the patient's means. One member sleeps on the roof in an army tent. Another put his mattress on the floor of a flat roof and slept on it, bringing in the mattress when it rained. He could not afford a cot. A third improvised a tent in a corner of the yard by throwing an old carpet over the side and back fence and over a clothes-line. Still another used a pole instead of a clothes-line and a rubber sheet instead of a carpet, thereby being able to remain out in the rain. Members sleep on porches, in back kitchens and in bedrooms with windows wide open, top and bottom.

The class meets once a week. It is a class in fact as well as in name. The first hour is devoted to lectures or talks by the class instructor and his assistant; to lectures and talks given by the patients themselves; to a general clinical conference in which the patients' records are criticized by both the instructor and the class members, and instruction is given by both; to public investigations into cases that do poorly to determine the cause, from which lessons are drawn for the benefit of all; and to a quiz to find out what the members know and do.

During the second hour the patients are seen one at a time, their chests or blood examined as required, and the treatment modified to suit the individual case.

It is in the management of the first hour that the University of Pennsylvania Hospital tuberculosis class differs from all other classes. The talks by the instructor teach not only the management of the disease, but its prevention as well. Sometimes I give the same kind of talk I give when addressing a labor union or a home and school association. At other times, especially when a new member is present, I outline the life a consumptive should lead. On different days I may give short talks on fresh air, food, clothing, bathing, the avoidance of infection, etc. The reason for each measure advised is always explained. I impress on the patients the particular need for hygiene in the members of their families, and the importance of having them examined, especially on the first evidence of ill health. The possibility of the occurrence of tuberculosis without much apparent illness is emphasized. I find this very necessary, as the husband, or wife, or other relatives, or a friend, of a patient who is improving will often insist that the patient has not consumption, because the picture of health presented does not conform to their preconceived notions as to the appearance of the disease. At one time I used to encourage the patients in the belief that they would recover completely, but during the past year I have been telling them they never will be cured, although they may become strong and able to work. I constantly remind them that the germs will always lurk somewhere in their systems, ready to become active whenever the patients relax their hygienic régime, and I endeavor to make them realize that for them eternal vigilance is the price of health. This insistence on the continuation of care and precautions throughout the patient's life renders a relapse less likely.

INSTRUCTION GIVEN BY THE PATIENTS

After the patients had been told the same things a number of times I noticed that they seemed to lose interest. As it was necessary for them to hear the same story over and over again, I conceived the idea of varying the monotony by having the patients themselves occasionally give the talks. It did not take long to discover that, despite their frequent instruction, the patients' knowledge was not always accurate, clear, well ordered, or available. When a patient who is lecturing makes a mistake I invite criticisms by the other patients, frequently stopping the speaker and asking one of the others if he agrees with the speaker, and, if not, why not. I always supplement the member's talk, explaining in greater detail the matters that apparently have not been made clear and laying emphasis on what has not been sufficiently brought out.

In this way the patients not only have their own knowledge better grounded and freed from inaccuracies, but they become proficient in giving lectures on the prevention of tuberculosis and the management of the consumptive, and are thus able to repeat to their relatives and friends what they have learned in the class.

Sometimes the older members of the class instruct a newcomer, one speaking on the disposal of sputum, another on the separation of the eating utensils, another on living in the open air, and so forth, always, of course, under the direct guidance of the instructor. The new patient listens attentively to those who are themselves following out successfully the directions they are giving. When a fellow consumptive describes his own arrangement for sleeping in the yard and his scheme for keeping his dishes, knife, fork and spoon separate, these things do not seem so impracticable and visionary to the skeptical new patient as when ordered by the physician.

When the instructor examines the patients' records he comments favorably or adversely, and also invites criticism from the class. A patient who has done poorly is made to describe in detail his life during the previous week, while the instructor and class try to discover the reason for his going backward. His error then furnishes a text for a talk by the instructor or by a class member. In this way all profit by the experience of each and are prevented from making similar mistakes.

In order to make sure that the patients do not forget what they are taught, they are questioned from time to time as to what they are doing and the reasons for it.

RESULTS OF THE CLASS TREATMENT

The results of this class treatment have been excellent. Nearly all the patients showed improvement. Large gains in weight were common. A great many patients, including some in the third stage of the disease and one who had suffered from severe laryngeal ulcerations, resumed their occupations. One man with cavities, whose fever remained over 103° for weeks at a time and who at first had to be kept at absolute rest, was walking five miles a day without fatigue and gaining in weight when he left the class to enter a sanatorium. A youth, who, in addition to his pulmonary lesion, had had two different severe attacks of bone tuberculosis with necrosis, worked eight hours a day, and in addition during the summer played on a ball team every evening and Saturday afternoon. He even started to play football until I found it out and stopped him.

An active educational campaign is carried on by the class patients. By precept and example they instruct relatives, neighbors and friends. The following case illustrates the amount of good they can accomplish: A patient always told her husband what she learned in the class. He, in turn, repeated the talks to his fellow workmen, with the result that ventilators were installed in the building where he was employed and windows were raised, and at noon instead of resting in the warm stuffy office, as formerly, many of the clerks took long walks. Some of the employees tried to convert their wives to proper hygienic living, and when a wife objected to fresh air at night, got up after she had fallen asleep and gently opened the windows. This same patient visits other persons known to have consumption or supposed to have "a cold" or "chronic cough," sees that they are properly looked after, and gives them advice and encouragement. She is now one of the friendly visitors of the Philadelphia Society for Organizing Charity.

A patient who was operated on for hemorrhoids in one of the general hospitals had to teach the nurses there how to keep her dishes separate and how to prevent her from becoming a source of danger to the other patients.

Two of the members who took up tuberculosis nursing surprised the other nurses with their knowledge concerning the management of the disease and their skill in taking pulse and temperature.

CASES SUITABLE FOR CLASS TREATMENT

I regard every ambulant tuberculous patient as suitable for class treatment. A high degree of intelligence is not essential. The instructor should be able so to present the subject that any mind can grasp it. I do not recognize the existence of the "unteachable consumptive." Even careless and combative persons have been inspired and spurred to action by their association with earnest and enthusiastic fellow sufferers, all eager to get well and to help each other.

The only really unsuitable patients are those who should be confined to bed for long periods of time. Yet I have sometimes included such in the class when it was impossible for them to procure a physician or gain entrance to a hospital or sanatorium. They either get out of bed every week or two to attend the class or a relative brings the patient's record to the class meeting and reports on his condition.

Some classes graduate the members when the disease is arrested and the patients are able to return to work. It is my belief, however, that they should always remain in the class, even if they attend but once a month. A number of the members of the University of Pennsylvania Hospital class are working. In fact, it is often these persons in whom the process has been arrested that are most in need of supervision, as they tend to become careless and in consequence suffer relapses.

ADVANTAGES OF THE CLASS METHOD OF TREATMENT

For ambulant cases the class method is, to my mind, the best method of treating tuberculosis. Its educational value to the patient, to his family, and to the public cannot be excelled. The patient learns how to live and work so as to keep well himself and not infect others.

In the ordinary dispensary there is not the time for the oft-repeated instruction and the constant questioning to find out whether the lesson has been well learned. Without the patient's record and the nurse's report it is impossible to know how thoroughly the directions have been carried out. The inspiration and spirit of comradeship engendered by the class is missing in the ordinary dispensary.

In the sanatorium the patient lives in a tent or shack or other building especially adapted for the fresh-air treatment, with every moment of his life outlined for him. Returning home to unfavorable surroundings and to people unfamiliar with the management and prevention of the disease, left to his own resources and often lacking the ingenuity to adapt the changed conditions to the life he should lead, he only too frequently falls back into the old ways that first rendered him susceptible to tuberculosis, relapses, and dies. This outcome is rendered more likely when the sanatorium treatment is made unpleasant as well as rigorous, in order that the patient shall not want to remain long, but shall try to be cured in six months and to remain cured, so that he shall never have to return. In such a case the patient comes to regard his treatment as something disagreeable, to be endured for six months for the sake of being cured, but to be avoided ever after. When proper living is forced on an unwilling patient by the discipline of an institution it is not so likely to be followed, after the removal of restraint, as when the compelling force comes from the patient himself, from his own understanding of the importance of, and necessity for, this mode of life.

The class method of treatment should be carried out in every tuberculosis dispensary. The increase in effectiveness will certainly justify the slight additional work or cost. Nor need there be any extra expense.

If class instruction were given to all sanatorium patients and if on leaving the institution they join a tuberculosis class, the good results obtained in sanatoriums would doubtless be more lasting and relapses less frequent.

I know of no other factor in the fight against consumption at once so available and inexpensive and withal so far-reaching and so lasting in its effects as the properly conducted tuberculosis class.

4102 Girard Avenue.

GONOCOCCUS VULVOVAGINITIS IN CHILDREN

WITH RESULTS OF VACCINE TREATMENT IN OUT-PATIENTS

B. WALLACE HAMILTON, M.D.
Physician to Children's Clinic, Presbyterian Hospital Dispensary; Clinical Assistant in Pediatrics, Vanderbilt Clinic
NEW YORK

Increased scrutiny in examining little children for admission to hospitals, asylums, day nurseries, kindergartens and other institutions has led to a surprising increase in the number of cases of gonococcus infection of the vagina seen in out-patients. The treatment of this class of patients, surrounded, as they generally are, by uncleanliness and poor hygiene, living in crowded tenements in families with no knowledge of the highly contagious character of the disease, has become a problem of much importance. A careful record has been kept of all the cases referred to the Vanderbilt clinic during the past three years, the total number of proved gonococcus origin being 344. These cases constituted a separate class in the department of pediatrics, and, through the interest of Dr. L. E. LaFetra, chief of clinic, additional facilities were extended regarding nurses and supplies. In the microscopic examination of smears from the vaginal secretion in all these cases, the organisms were decolorized when stained by Gram's method. All cases from which the smears showed either extracellular organisms, or those which were not decolorized, are excluded from these statistics. In many instances the first and second smears failed to show the gonococcus, but subsequent examinations revealed it. The doubtful or "suspicious" cases showing many leucocytes in the stained smears of the secretions are *not* here considered.

With the older children an endeavor was made to discover the extent of invasion by the gonococcus at the time of obtaining the smears, to find in what proportion of cases the parts beyond the hymen were involved and how deeply the gonococcus penetrated. A piece of glass tubing, 3 inches long, 1/4 to 5/16 of an inch in diameter, its lumen at least 1/8 of an inch, was threaded with a string to whose middle was tied a cotton plug. The ends of the loop were then tied and the portion passing through the tube was drawn on so that the plug became firmly fixed in one end of the tube. The whole was sterilized and then introduced into the vagina as far back as the posterior cul-de-sac; the cotton plug, to prevent contamination by the secretion about the vulva, was then removed by drawing on the outer string, a platinum loop was then introduced through the lumen to the posterior cul-de-sac and a loopful of the secretion was removed.

It was possible to examine 40 cases in this manner. The very important result of these investigations was that in every one of the 40 cases gonococci were found to have invaded the upper part of the vagina.

In 15 cases in which the hymen was not intact, a visual examination of the cervix was made by means of a male urethral speculum and head mirror; in but one case the cervix was congested and slightly inflamed; in all the others the cervix was tightly closed and sealed by the normal mucous plug. The cervical canal, endometrium and their adnexa are apparently very seldom infected by continuity in little children.

AGE

In the 344 cases observed, the average age of the patients was 5.1 years; the youngest was 3 weeks; the oldest was 12½ years. One hundred and fifty-one patients were under 5 years, the remaining 193 being over 5 years of age.

ETIOLOGY

	Cases.
Discharged from hospitals	60
Referred from day nurseries and kindergartens	24
Referred from orphan asylum and foundling home	3
Mother giving history of leucorrhea	70
Mother giving no history of leucorrhea	75
Sleeping with sister giving history of vaginal discharge	28
Sleeping with sister giving no history of vaginal discharge	29
Sleeping with child giving history of vaginal discharge	3
Sleeping with child having ophthalmia	2
History of "attempted rape"	1
Unknown etiology	49

In 4 cases there was direct evidence that the father, mother and the child all suffered from gonococcus infection at the same time, the father having the original urethral infection.

In 8 instances there was direct evidence that the mother had had a discharge shortly after marriage. In these cases there was urinary evidence of a previous urethritis in the father.

There was one instance of infection of 4 children of one family; 3 instances of infection of 3 children of one family; 19 instances of infection of 2 children of one family. In 7 hospital cases and 4 which were not hospital cases, the infection had followed scarlet fever.

DURATION OF VAGINAL DISCHARGE PREVIOUS TO COMING UNDER TREATMENT

	Cases.	Average Age, Years.
5 years	3	8.2
4 years	4	7.6
3 years	2	8.1
2 years	9	8.0
1½ years	22	4.6
1 year	12	3.1
6 months to 1 year	52	4.5
6 months to 3 months	55	5.3
3 months to 1 month	42	5.9
Under 1 month	143	5.2

SYMPTOMATOLOGY

Most of the cases gave a history of burning micturition, without undue frequency, at the onset of the discharge.

Edema of the vulva was generally present, but of short duration after treatment was instituted.

Discharge was present in all cases, the majority having the thick, yellow purulent type. The length of time the discharge remained purulent depended greatly on the cleanliness of the mother, being in inverse ratio to her efforts. Clean underclothing and frequent bathing of the vulva shortened the time of the purulent discharge. A mucous discharge, so small in amount as not to stain the child's clothing, may be indefinite in its duration and contagion. This was proved in many cases in which the patients returned to the clinic, when requested by postal card, after no treatment for a period as long as two years, the mother thinking the child cured when the clothing was not stained by the discharge. The gonococcus was present in 14 cases out of 61 patients who returned, with no treatment for periods from two years to six months. These 61 cases had previously been discharged as cured, after local treatment by irrigations.

COMPLICATIONS

Ophthalmia from auto-infection strangely enough occurred in but four cases; one of these resulted in marked corneal ulceration and partial blindness.

Arthritis was present, as far as ascertained, in only 3 cases; 2 involving the ankle and 1 the knee. It is presumable that more cases occurred, but it was difficult to obtain any such history on account of the cases being out-patients.

Nocturnal enuresis, not pre-existing, was present in 10 cases. The majority of these cases improved with local cleanliness.

Inguinal adenitis was very infrequent, occurring in only 2 cases. Neither one suppurated, subsiding under rest in bed and local applications.

No cases of cystitis or urethritis were observed, and there was not a single instance of pelvic or general peritonitis, though such cases have been reported by others.

In a number of the older children, masturbation was most likely a factor in prolonging the inflammation and the discharge.

TREATMENT

Printed instructions were given to each mother containing information and directions on the following points:

1. Vulvovaginitis in little children is a local contagious disease which requires treatment until the physician pronounces the child cured. It sometimes persists for months.

2. To avoid infecting other members of the family, the hands should always be washed thoroughly both before and after bathing the parts. The discharge, if carried to the eyes, may cause blindness.

3. The child should sleep alone. No one else should use any toilet articles, towels, napkins or wash-cloths used by the patient. All napkins, sheets, underclothing, towels and wash-cloths should be either boiled or immersed in a phenol solution before washing. Bath-tubs, basins and everything else coming in contact with the patient should also be washed with this solution.

4. It is advisable that all children with this disease should wear a napkin or pad, which should be changed daily.

5. Parents are cautioned not to allow the child to mingle intimately with other little girls. The child should not attend school or day nursery lest other children become infected.

6. The parts should be cleansed externally at least four times daily with a solution of borax or boric acid crystals, one teaspoonful to a pint of boiled water.

TREATMENT BY IRRIGATIONS

The following irrigations were tried:

1. Potassium permanganate, 1 to 4000 solution.
2. Condy's fluid,[1] 1 dram to a pint (this is a solution of potassium permanganate and alum sulphate, in which, by the combination, a larger amount of available oxygen is evolved)
3. Physiologic salt solution, 0.9 per cent.
4. Boric acid solution, 3 per cent.
5. Formalin solution, 1 to 1000.

The best results as regards cleansing were obtained with Condy's fluid.

The following instillations, in each of which two drams of the solution were instilled, were tried in conjunction with the irrigations:

1. Silver nitrate	1 to 5 per cent. solution.
2. Protargol	1 to 10 per cent. solution.
3. Argyrol	20 to 50 per cent. solution.
4. Ichthargan	½ to 5 per cent. solution.
5. Collargol	1 to 5 per cent. solution.
6. Ichthyol	1 to 10 per cent. solution.
7. Emulsion *Bacillus bulgaricus.*	10 to 50-per cent. solution.

Treatment by tampons of ichthyol, 5 per cent. and ichthyol 2.5 per cent. with iodin 1 per cent. and hydrastis 5 per cent., were tried with poor results.

Suppositories of 10 per cent. ichthyol were used with no permanent results.

Each mother was instructed in the clinic and at her home in the care of her own hands, both before and after the treatment, the preparatory cleansing of the vulva, the preparation of the douche, the sterilization of the catheter and the introduction of the catheter. This was done by actually making her give the douche in the clinic, by printed instructions and by the nurse visiting the home to see that the treatment was properly carried out. The nurse's visits were continued if the patient did not make a weekly visit to the clinic, as was ordered in all cases. When patients lived at a distance, postal cards were sent to them, and in this way a fairly close record of the attendance was kept. The danger of "overtreatment" was reduced to a minimum by frequent examinations of the child at the clinic.

The method of treatment was as follows: The child was placed in a dorsal position with the thighs flexed on the abdomen. The labia were held apart while the vulva was carefully sponged with an antiseptic solution (1 to 4,000 bichlorid of mercury). The sterile catheter attached to a fountain syringe, after being anointed with sterile lubricant, was gently introduced into the vagina. Two quarts of solution were used as the irrigation. Once weekly this routine was carried out in the clinic, and an instillation of one of the astringent silver preparations was given before the catheter was removed, by means of a glass hand-syringe. The foot of the table was kept elevated and the instillation was allowed to remain for a period of five minutes. Irrigations were given by the mother at stated intervals at home; if the secretion was profuse they were given daily, the intervals were made longer as the secretion lessened in amount. Irrigation solutions were tried at varying temperatures, ranging from 105 to 120. No apparent benefit was noted following temperatures over 110.

TREATMENT BY VACCINES

Following the results of Cole and Meakins[2] in the use of vaccine therapy in gonorrheal arthritis in adults, the record of 25 cases reported by Butler and Long[3] and 41 cases reported by Churchill and Soper,[4] the two latter in children with vulvovaginitis confined in hospitals, the same treatment was undertaken in out-patients. Eighty-four patients in all have been treated by this method. Because the patients were out-patients, because of the lack of time and because of the experience of others in the use of the vaccine in adults, I omitted taking the opsonic indices, except in a few of the early cases. I do not deem it necessary to take the opsonic index, as there seems to be little relation of the index to the vaginal discharge.

---

[1] Condy's fluid, according to the National Dispensatory, is made by mixing 53 parts of potassium permanganate, 333 parts of crystallized aluminium sulphate, and 777 parts of hot water. On cooling, potash alum crystallizes out, which is separated from the liquid. The latter hence consists of a solution of potassium sulphate and permanganate of aluminium. The U. S. Dispensatory states that "all the available oxygen of the permanganic acid is utilized, whereas only 60 per cent. of this amount is utilized with the simple alkaline permanganate."

[4] Churchill, F. S., and Soper, A. C.: Inoculation Treatment of Gonococcus Vulvovaginitis in Children, THE JOURNAL A. M. A., Oct. 17, 1908, li.

Three separate vaccines were used:

1. Vaccine prepared from 16- to 18-hour blood-agar cultures from acute male urethritis, prepared after the method devised by Wright by Dr. R. V. Lamar of the Rockefeller Institute for Medical Research. The strength of the emulsion was 100,000,000 killed bacteria to 1 c.c.

2. Vaccine from a stock culture at the Presbyterian Hospital belonging to Dr. J. C. Meakins. The strength of this emulsion was also 100,000,000 to 1 c.c.

3. Stock vaccines prepared by Parke, Davis & Co., the strength of which were 50,000,000, 100,000,000 and 500,000,000 per cubic centimeter. No attempt was made to use the autogenous or personal vaccine from the patient's own organisms.

The injections were made under strict asepsis into the gluteal muscles with an ordinary glass hypodermic syringe. In using small quantities of the vaccines, sterile physiologic salt solution was employed as a diluent.

The number of vaccinations in the individual cases varied according to the age, severity and chronicity, the smallest number to accomplish a cure being four and the greatest number being eighteen.

In endeavoring to arrive at some conclusion regarding the dose of vaccine to administer to children, I selected an older child who had been affected for a long period and whose parents were more intelligent than the ordinary out-patient. A large dose was injected for three consecutive days, the child being put to bed under the constant care of a trained nurse. This child was 8 years of age and had been treated by the irrigation method for seven months. I injected 1,000,000,000 killed bacteria into her buttock at one dose each day, and had her temperature and pulse taken every two hours. She not only showed no rise of temperature, but no local reaction whatever and no subjective symptoms.

In the majority of cases, regardless of age (except under 6 months) I started the treatment by an injection of 50,000,000 every fifth day, increasing the dose by 10,000,000 until five injections were given, i. e., 90,000,000. The interval was now made ten days before another was given. Smears of the remaining secretion were taken and stained by Gram's method at each visit after the fifth injection. In most of the acute cases six injections were sufficient for a complete cure. In the cases of long standing it was necessary to use an increased number of injections, bringing the dosage up to 200,000,000.

No patient was pronounced cured unless free from gonococci by Gram's method, once weekly for four weeks and two additional examinations at intervals of two weeks. If no gonococci were present after these six examinations and no discharge evident, I considered the child cured. I have had 19 children return to the clinic after a period of three months following their sixth examination and found no evidence of the infection present.

Occasionally an extremely slight local reaction took place, but this in every case subsided in twenty-four hours. The reaction was never sufficient to cause any pain or tenderness. General constitutional disturbance never occurred following any of the injections. Temperature charts were kept of the cases, the temperature being taken twice daily by the visiting nurses, who visited the patient's home while active treatment was being given.

No distinct rise in temperature following an injection was noted in any of the cases. No local treatment whatever was used, except external bathing, if excessive discharge was present. No irrigations were given.

Of the 84 cases treated by vaccines, 16 were of long standing which had been treated by other methods. In the majority of these 16 cases permanganate irrigations were previously used. Gonococci were present in all before instituting the vaccine treatment. These latter cases required a larger number of vaccinations and an increased dosage.

RESULTS

Treatment.	Total No. of Cases.	Cured.	Uncured.	Lost.	Per Cent.
Irrigation	260	158	53	49	60
Vaccines	84	76	5	3	90

Average length of time under active treatment by the irrigation method, 260 cases, 10.1 months.

Average length of time under active treatment by the vaccine method, 84 cases, 1.7 months.

Of the 84 patients who were given the vaccine, 16 had been under the irrigation treatment for long periods. Three of these patients were not benefited, 1 did not return and 12 were cured. Some of those who did not respond to the treatment with one vaccine frequently did well on one of the other vaccines. In the cases in which there was no benefit, new strains were used; increased dosage, less frequent dosage and more frequent dosage, was tried but with negative results. The 5 uncured patients were all over 5 years of age, two of them being over 9 years. Contrary to the findings in some other published results, in young infants, under 1 year of age, three cures were obtained by the vaccines, the youngest patient being 3 weeks old.

CONCLUSIONS

Vaccine therapy has a place in the treatment of this infection in little children for the following reasons:

1. The short time required for a cure in over 85 per cent of cases.

2. The ease of administration of the vaccine; no special apparatus or knowledge of technic being necessary.

3. The vaccine is apparently harmless when used under aseptic precautions.

4. It is not necessary to take the opsonic index, with its complicated technic.

5. It eliminates irrigations, which direct the child's attention to its genitals, at times encouraging precocious masturbation. The frequent douches necessary in the irrigation treatment will, with the best care and gentleness, produce some injury when continued over a long period of time.

I wish to express my thanks, for the clinical cases referred to me from other hospitals and clinics, to Dr. R. V. Lamar of the Rockefeller Institute for Medical Research and Dr. J. C. Meakins of the Presbyterian Hospital, for cultures and vaccines, and finally to the visiting nurses' staff of the Vanderbilt Clinic, who have aided in making this record of cases possible.

BOTTLED MILK AS A HEALTH MEASURE

AND SOME OF THE DIFFICULTIES ENCOUNTERED IN SECURING A PURE MILK-SUPPLY

J. MORTON HOWELL, A.M., M.D.
DAYTON, OHIO.

There is to my mind no more important matter for public consideration and action than the one of pure milk-supply, for the manifest reason that on this food product at least 50 per cent. of the present, and probably each succeeding generation, will depend for subsistence.

The best records up to 1910 show that ten bottle-fed babies die to one that is breast-fed. It has been demonstrated, within the past five years especially, that there is no reason to believe that the alimentary canal of the average infant is often incapable of digesting the food necessary for normal growth and development, when the food supplied, even though this is cow's milk, is of suitable quality and quantity; indeed, since strenuous hygienic lines have been drawn by men of our profession in some cities throughout the country the mortality rate has been lowered 20 per cent., and in a few cities, where the contest has been waged with great vehemence and intelligence, 50 per cent. salvation has been achieved.

If we would form anything like an adequate conception of the loss in mortality to child life, due wholly to filthy and adulterated milk, we shall need make some inquiry into statistical records along these lines. The reports of the U. S. Census Office for the year 1905 declare that the malign effects of artificial feeding of infants and the consequent impress made on the mortality returns become manifest by an examination of the vital statistics, but to gauge the exact ratio of infant deaths resulting from artificial feeding is very difficult. We have some very startling figures in this report, however. In a registration area with a population of 33,000,000 there were 105,553 deaths among infants under one year of age. Diarrhea and enteritis caused the death of 39,399 children in the first year of life. The U. S. government report for 1908 shows a total of 400,000 deaths of infants, and the report concludes that 200,000 of these could be prevented.

"About one-fifth of the total loss of life in the first year after birth," writes the Registrar-General of England, "takes place within a week of that event, while by the end of the first month the proportion reaches one-third, and by the end of the third month it exceeds one-half. From the first to the fourth month diarrheal diseases steadily increase in destruction."

In Paris and the cities in France having over 30,000 inhabitants the deaths from diarrhea by months per thousand infants under one year were as follows: June, July, August, September and October the average was 525, or more than one-half of all born during these months succumbed to gastro-enteric trouble.

According to Behring of Germany, of every 1,000 children born alive, 235 succumbed during the first year of life. Only 510 out of every 1,000 males born attain manhood. Not more than a third of those reaching maturity are found to be fit for military service. These sad facts he attributes very largely to the ulterior effects of infection derived in infancy from milk.

In the face of these astounding figures and facts we find that to better these conditions, which have cost and are costing us so dearly, is a problem of gigantic proportion and the elements entering into its solution are varied and complex.

In the first place, as soon as any one attempts to institute reform measures he meets with opposition on the part of the producers. This opposition is due to two causes—ignorance and a desire to receive the largest possible return for their product with the least amount of outlay. Of course, this second reason is really based on the first, ignorance, for it is now a well-known fact that our most up-to-date milk producers, those giving the most careful heed to all matters pertaining to sanitation, are really the men to whom the business is worth while from a financial standpoint.

While I have placed the milkmen, or rather their filth, first in the enumeration of factors in the death-rate of children, I do not regard them as our greatest foe, for they can be educated, coerced by law, or eliminated from the business by reason of non-compliance with the regulations affecting their product.

It has been my observation that time-serving politicians who have the appointing of boards of health, and their political allies, are the greatest menace to the furtherance of measures to prevent this onslaught on these helpless children. This condition of affairs prevails on the part of these office-hunters by reason of, first, their inordinate desire for office at any price—even at the cost of human lives; second, their ignorance of the grave questions involved in settling matters pertaining to higher sanitation, and, therefore, their utter inability (or, if not inability, unwillingness) to select men for this important work who have the intelligence, perseverance and firm decision of character to stand for the right at any cost. In other words, men are selected whom they believe they may dominate or control in the interests of their party.

Some of you may think I have overstated the condition that obtains throughout the state. Let me, therefore, refer to a few facts gleaned from the history of a certain municipality within this state having 125,000 people. The mayor stated before the council that the board of health of this particular city had been extravagant in that they had raised the salary of the clerk of the board from $1,000 to $1,500 and the salary of the health officer from $1,100 to $2,000 (although he, the mayor, was drawing $5,000 and his own clerk $2,000). He further stated that members of this body had exceeded their authority in that they had employed one extra meat inspector, making two for the entire city, with more than thirty slaughter houses to inspect, besides hundreds of markets throughout the city. This statement was made in the face of the fact that the statutes give to the board of health the right to employ as many meat and milk inspectors as they may deem necessary to carry on the work of sanitation. Not only do we find personified ignorance of the matter to which I have above alluded, but we find in this same municipality this same office-seeker siding with milkmen whose bacterial count runs into the millions, and the temperature of whose product was as hot as the streets on which it was being hauled during the days of July and August. I could go on *ad infinitum* touching these matters pertaining to this municipality, but suffice it to say that in the election the mayor received the votes of every man who was opposed to bottled milk, of every voter who desired to sell tuberculous and cancerous meat, of every citizen who had the right of franchise who was opposed to lifting his produce from the sidewalk a distance of two feet, so that it could not be contaminated by dogs, etc. He was sustained at the polls by every meat vendor who was opposed to screening his meat in the market to protect it from the deadly germ-carrying flies, and by every foreign and domestic voter who desired to supply so-called ice-cream, made from the most questionable products in most questionable quarters and containing in many instances not more than 4 per cent. butter-fat. Those engaged in peddling this product in cones (the latter handled by individuals whose personal habits as to cleanliness were superlatively bad, and whose practices in this line of dangerous work had been prevented—stopped—by effective legislation) supported him. In the last place, although not least, all the citizens who desired to run their businesses 365 days and nights of the year, except, it may be, on election days, supported this mayor that they might run in open defiance of a law which he had taken an oath to respect and execute.

He and his friends refer to his administration as a "business administration." Who pays the price? Can you count the cost of such a business administration?

This last illustration may be a little foreign to the qustion at issue, and my only object in referring to it is to show, or perhaps further to emphasize, that if we would obtain the highest standard in matters of sanitation and life saving, the work of departments of health must be divorced as far as possible from politics as politics is now understood and practiced in many cities and towns throughout this country.

I am not criticizing the man or the citizen, but the politician and those who control his political action in adopting methods to further political ambition at the cost of human life.

It is argued and apparently believed by many of these politicians to whom I have referred that the work of the health officer is of minor importance and that young and inexperienced physicians are glad to take the place for $1,000 to $1,200. That may be true, but we know that such men as these are overpaid even at such salaries. The fact is that, if progress is to be made along these higher lines, the work demands the most symmetrical, experienced and generally well-informed man that can possibly be secured for this very important work, and it is an insult to our profession to ask that this work be done for such compensation as I have mentioned.

It occurs to me that a member of the board of health should have license to state the truth and the whole truth regarding these obstructions to the securement of better and saner policies along these lines or matters in question, for throughout this state each member serves without financial compensation, and his only reward can be a knowledge of a duty well performed, and no one, therefore, may truthfully say of him that he is disgruntled by discontinuance of service.

As to bottled milk as a health measure I beg to recite some experiences in my own city touching this question. Notwithstanding strong organized opposition, the Board of Health of the City of Dayton passed and successfully fought through the courts a bottling regulation or provision which, when executed, will save scores of young lives every year. Inasmuch as the provision is the first of the kind within the state, and for that matter in the United States, I have thought it might be of interest to give it here *verbatim*, with the salient points, as well as those specifically controverted.

Section 1.—No person, firm or corporation, except such as may sell for consumption on the premises where sold, and dealers in dairy products exclusively, shall sell, offer for sale, expose or keep with the intention of selling any milk or cream, or both, in the City of Dayton, Ohio, unless such milk or cream is kept, offered for sale, exposed for sale, or sold in tightly closed and capped bottles or receptacles of a similar character which may be approved by the board of health of said city; the owners and operators of dairies, and all drivers of wagons who sell milk or cream at retail or deliver the same from wagons, shall carry, sell and deliver such milk and cream only in bottles or other approved receptacles as aforesaid. All milk and cream so sold in bottles or other receptacles, not to be consumed on the premises where sold, shall be taken and carried to the residence of the purchaser or plade where intended for use in the said bottles or receptacles, and not otherwise.

Section 2.—No milk or cream shall be sold, offered for sale, exposed for sale or kept with the intention of selling in or at any milk depot, creamery, store or other place of business, unless such milk depot, creamery, store or other place of business shall be equipped for keeping said milk and cream, and the same shall be kept therein, at a temperature of 50 degrees, or lower, Fahrenheit.

Section 3.—The provisions of Section 1 of this regulation shall not apply to *bona fide* dealers in milk and cream at wholesale who shall sell at any one time a quantity of not less than two gallons of milk or two quarts of cream, and who shall each have a separate room in which said milk and cream shall be kept or offered for sale, with a floor space at least ten feet square, with suitable ventilation, and provided also with an additional room in which shall be washed and cleaned all cans, bottles, or other receptacles, and utensils of every kind used in connection with said business, all of which shall be subject to the approval of the Board of Health.

In a suit brought to test the validity of this regulation the plaintiff contended that it was unconstitutional and void, that it was unreasonable, that it was burdensome, that it was partial and did not act with uniformity on persons of the same class, and that it made unjust discrimination between them, and that it destroyed vested property rights, etc. Of course, in our answer we denied all of his allegations, except that he was engaged in the dairy business. We held that the purpose for which the regulation was passed was one of sanitation and preservation of health, first, to secure to the customer an equal distribution of butter-fat or a requisite amount required by law, 3 per cent. (a result out of the question under the old method of dipping from the cans); second, to prevent the delivery of milk to customers in unclean vessels furnished by them; third, to prevent dirt, dust and disease germs from coming in contact with the milk.

The court held that, in so far as the first purpose was concerned, the seller is not required to distribute the butter-fat equally among his customers. If he brings his deliveries up to the standard required by the Revised Statutes, 4200-12, he has met all the law of the state demands. We contended, and do now contend, that it is not only unsafe for the dairyman to attempt legal fulfilment of the law by handling of milk in cans for retail, with the dipping process, but that it is unsafe to the customer, in that he is cheated of one of the essential factors in milk necessary for the life and sustenance of children, to say nothing of the dangers of contamination under the old process.

As to our second ground the court said: "It is certainly not fair to impose regulations on one man because of the negligence or folly of another" (referring to containers placed out by customers for the reception of milk). Then the court proceeded to the third reason or ground held by us for requiring bottled milk, to wit: that dirt, dust and pathogenic germs come in contact with milk in cans which are being continually opened for the dipping of milk. This was given by the board, as the principal reason for the adoption of the measure in question and was held by the court, after hearing all the evidence, to be reasonable and in conformity to law and common decency.

One fly falling into the pail has been shown to be capable of introducing 250,000 germs into the milk. Now, in some of the streets and alleys through which these milkmen drive their wagons, and from which they dip here and there to supply their customers, are not garbage-cans full and running over with morbific matter, which in some cases has been standing for weeks, without municipal interference, at a temperature of this climate in July and August? In the poorer sections are not these garbage-cans the receptacles into which cuspidors have been emptied, filled with sputum deposited there from the cavities of lungs of individuals in the last throes of consumption? Flies which have fed thereon and which have their bodies and legs teeming with the germs of tuberculosis leave this morbific feast to follow the milk-wagon and sup on the fresh milk that has fallen from the filthy dippers; not infrequently they fall into the can as the lid is removed to supply the next customer.

It needs no argument to convince one that milk delivered in bottles may be as insanitary and as disease-producing as that delivered in cans. Milk is no cleaner than the dirtiest thing it touches. Any bottles, can, pail, cooler or other appliance, if dirty, is a source of contamination. I am presuming when dealing with the bottling measure that the cattle have been tested for tuberculosis. This, however, is presuming too much, for many, many herds throughout this state are alive with tuberculosis, as was one recently supplying milk to Dayton, where, when the test was made by the state examiner at our instance, every cow of the entire herd of thirty-one was condemned and destroyed; and I wish to add that this important question of state inspection must be taken up in a way that will eliminate this great danger.

Under this regulation, I presume that the barn, the source of water-supply, the utensils used in milking, the toilet of the milker, the condition of the cow as regards cleanliness, is all that may be desired, or has passed muster of the dairy inspector. I contend that the milk so secured and delivered other than in bottles is a most flagrant source of disease and death.

It is indeed, a most difficult problem to render a can which has been used for some time sterile. The seams and indentations about same are most difficult, indeed, if possible, to clean, whereas bottles have a smooth surface and, too, are transparent, so that much may be discerned by inspection both by the seller and the buyer. By adhering to the following technic (all other precautions which I have enumerated having been followed out) the dealer will place a product within the hands of the consumer that means salvaton to children who have hitherto been sacrificed to dirt and greed.

First, wash the bottles in pure cold water; second, scrub them thoroughly with a brush, using hot water and some good soap powder; third, rinse them again in hot water; fourth, scald them out thoroughly with boiling water (steam is preferable to boiling water and should always be used when at hand); containers should be subject to boiling water or steam at least from five to seven minutes at a temperature of 212.

The temperature at which milk is held after cooling has much to do with its quality and fitness for food, especially for infants and children. One germ in milk at a temperature of 70 degrees will multiply itself 250 times in twenty-four hours. It is practically out of the question to deliver milk in cans in retail without the temperature of the milk reaching 70 degrees and above during the summer months or heated term; this means a product running into the millions of bacteria, both common and pathogenic; whereas in bottled milk, if the precaution is taken to which I have alluded, and these bottles filled with milk placed in crates surrounded by ice, a delivery should be made at a temperature never exceeding 60 degrees.

It is remarkable what may be accomplished by legislation and execution of the legislation touching these matters of cleanliness.

Men who have hitherto appeared to be wholly indifferent to all these important points of sanitation will be found inquiring diligently what they may do to be saved. It is then that a campaign of education may be of great benefit.

Dairy inspectors should be instructed (and they should be high-class men, possessing scientific knowledge *on this subject) to advise the producer along all practi*cal and scientific lines touching his product. The producers should be supplied with the practical literature furnished by the U. S. government touching all points in question.

The health officers should meet the producers in their dairy association and show them that for them to take higher rank and furnish a clean and safe supply of milk is for them not only to enhance their own financial well-being, but thereby to become great public benefactors and saviors of their race.

The matter of the urgent necessity of great care in the handling of all food products by reason of the dangers arising from carelessness is emphasized in a well-known case reported by Dr. George A. Soper,[1] that of a healthy woman, a cook, who had lived in many different families during a period of ten years preceding 1907, in each of which there developed in from 3 to 4 weeks after the cook had entered on her duties, typhoid fever among members of the household. In all twenty-eight cases of this disease were traceable to this source. The cook was removed to a reception hospital for observation. She denied ever having had the disease. Examination of the blood and urine was negative, but the bowel discharges were found to furnish cultures of the typhoid bacillus. The mode of infection is clearly indicated by the woman's occupation, and is a sad commentary on her personal habits of cleanliness.

It should be insisted that examiners or dairy inspectors inquire, not only subjectively but objectively if necessary, into the personal physical condition and habits of the handlers of milk.

During my administration as president of the Board of Health of Dayton many cases of what should probably be regarded as criminal negligence along this line have come to my attention. Nothing but the closest scrutiny on the part of those in charge of the work will eliminate this source of danger.

This work of reformation is an arduous one and one fraught with much discouragement. None but the strongest heart and bravest soul need enter the ranks, but those who are clear of head and honest of heart need not fear for their reward; it may not come in dollars and cents, but it will come, and come with a sense of duty well done.

307 Reibold Building.

AN IMPROVED METHOD OF TRACHELORRHAPHY

WILLIAM L. WALLACE, M.D.
SYRACUSE, N. Y.

The operation of trachelorrhaphy has so often been unsatisfactory that the tendency has been to substitute amputation of the cervix. Repair of the cervix, however, is so simple; and, when the result is good, the patient is left in so much better condition than after amputation that it is well to search for the cause of the dissatisfaction and try to find some way to make the operation successful. The trouble with trachelorrhaphy is that the site of the repair is apt to be so thin that it cannot possibly withstand another labor. A section through such a repaired cervix would show a cavity barely closed at the side. This poor result is brought about, I believe, by the faulty method of through-and-through stitching by which the side of the cervix is compressed to thinness, the ligature drawing the mucous membrane within the canal almost into apposition with the mucous membrane covering the cervix.

The usual repair is made by cutting through and removing the scar tissue at the site of the old laceration, denuding the anterior and posterior lips from the depths of the angle to the apex of each lip, and closing the wound with several through-and-through stitches. Some surgeons use catgut, but many find that, on account of the narrow apposition, the catgut will not hold, and hence use silkworm gut or silver wire. Such a repair looks well, but the poor result is evident if, for any reason, it should be decided to amputate the repaired cervix. While the denuded lips were from one-half to three-quarters of an inch wide, the repair is only from one-eighth to one-quarter of an inch (Fig. 1). In such a cervix, the eversion, to correct which the repair was made, quickly returns with its unhealthy discharges, and the next labor tears open the double layer of mucous membrane which alone has held.

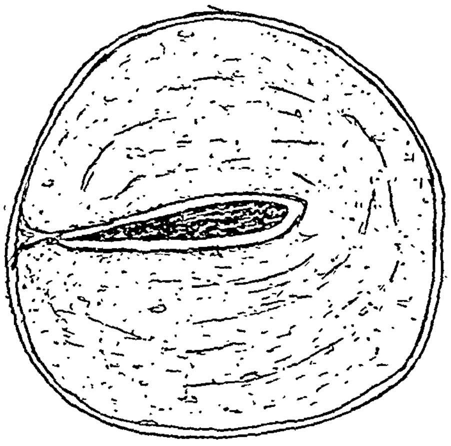

Fig. 1.—Amputated section of cervix, showing poor result of right unilateral repair.

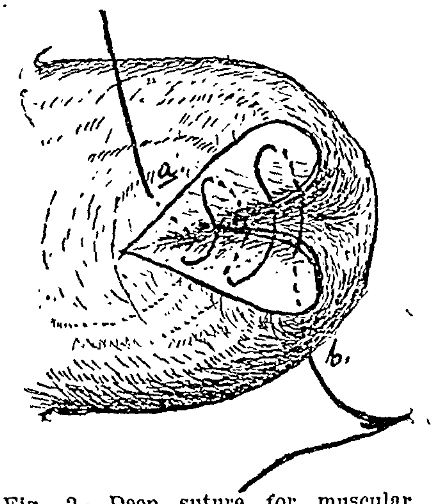

Fig. 2.—Deep suture for muscular layer starting at *a*.

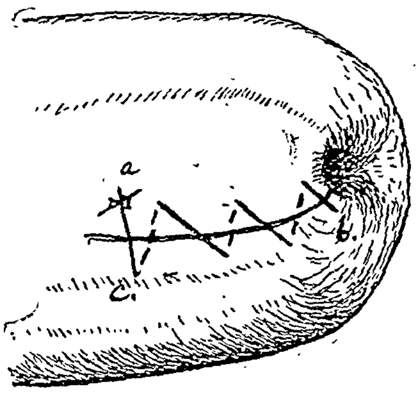

Fig. 3.—Superficial suture running back from *b* to *c*, and then tied with end *a*.

What steps can we take to make the repair a success? How can we bring together the broadly denuded muscular surfaces of the anterior and posterior lips without narrowing them? A repair of the cervix, I believe, should follow the method of layer suture so successfully used in closing the abdomen. I use a continuous suture in two layers. The needle is entered through the outside of the cervix near the angle of the wound (Fig. 2, a). This suture is carried very deeply back and forth into the muscular layer of the anterior and posterior lips, coming out at the front of the opposite lip (Fig. 2, b). Each stitch is pulled up as the operation proceeds, broadly approximating the depths of the wound. The suture goes to the edge of the mucous membrane of the cervical canal, passing through the superficial parts only at the points of beginning and ending. The superficial layers are then drawn together by running back the same continuous suture, coming out opposite the point of starting (Fig. 3), where the two ends are tied together. An amputated section of this cervix will show that it is equally thick in all parts and therefore properly repaired.

I use No. 1 chromic catgut, no tension on the stitches being required to hold the broad surfaces together. In case of bilateral laceration, I split and denude both sides, and then repair completely first one side and then the other.

In many cases it will be found that the cervix shows on one side a slight laceration without scar tissue, while on the other side there is a deep laceration causing hypertrophy, eversion and erosion. In these cases I do a unilateral repair, a wide wedge being removed from the bad side by which the hypertrophied parts are virtually amputated. While this will place the os uteri slightly on the side that has not needed repair, the operation is done with half the danger and in half the time required for other procedures, leaving perfect drainage with no possibility of stenosis. The cervix soon straightens itself and within a few months the os will be found at the apex. In many cases a deep wide unilateral operation is much better than a bilateral repair.

This method of layer suture on one or both sides is very simple and rapid and the result has been wonderfully satisfactory in my experience.

1000 East Genesee Street.

FORMALDEHYDE POISONING

HENRY F. HOYT, M.D.
EL PASO, TEX.

History.—A. K., a Japanese merchant, aged 24, had been given some medicine to take after meals—"a teaspoonful in a glass of water." He put the required amount into a glass and looked about for some water. He was in his place of business, into which he had just moved, and seeing on a table a gallon bottle labeled "Stafford water," a mineral water much used here, left by the former occupant of the premises, he filled the glass from the bottle and, as is often the case when taking medicine, did his best to gulp down the mixture as quickly as possible. He succeeded in swallowing over half of it before he discovered that something was wrong. He called for help, and as I was near I reached him in about a minute.

Treatment.—In that short time he was already in a state of shock with convulsions and only partly conscious. His assistants, all Japanese, were excited almost to frenzy, a condition which played such havoc with their limited English vocabulary that it was impossible to ascertain what had happened. I decided that I had to deal with a case of poisoning but of what nature or kind I had no idea. Seeing some salt on the table and a kettle of hot water on the stove I ordered them to make him swallow as much salt water as possible and to rub him vigorously at the same time, while I rapidly prepared a hypodermic of .0065 gm. of apomorphin. By the time I administered this they had succeeded in getting down about a pint of the solution. In a short time the emetic acted vigorously and continued to do so until we had refilled and emptied his stomach several times.

His tongue, mouth and throat were blistered but there was nothing in the odor of the stomach contents to give a clew as to the kind of poison he had taken. After he had rallied from the shock and the others had calmed down enough to talk coherently, I got the facts of the case. I removed the cork from the bottle of supposed "Stafford water," smelled the contents and my diagnosis was made. The "water" was a solution of formaldehyde left by the former tenant and was found to be the standard 40 per cent. mixture. From the patient's statement later he must have swallowed at least 100 c.c., possibly 120.

He developed a severe gastritis, with very sore mouth and throat, but made an uneventful recovery in about ten days.

This is the only case of formaldehyde poisoning I have ever seen and I find very little about it in the literature at my command. It is my opinion that, had the stomach not been full when he took the dose and had it not been emptied so promptly, the case would have terminated fatally.

A PECULIAR CASE OF MERCURIAL POISONING

BURNLEY LANKFORD, M.D.
NORFOLK, VA.

The following case is submitted because of the unusual method by which the mercury was introduced into the system:

History.—Mrs. — sent for me hurriedly one afternoon; she was seen first at 7:15. She was very nervous, crying, and said that she had awful pain in her head and that fearing that she was pregnant, because the week previous her menses had lasted two days instead of four, she had followed the advice of a woman of her acquaintance, and two hours before calling me had inserted as deep as possible into her vagina two mercury bichlorid tablets (gr. 7.3 each). She had had no idea that they would hurt her, but she was having much pain and thought she was swollen. An examination was at once made. Each labium was found to be at least an inch thick, very red, tense and shiny, having a brawny feel. With some difficulty, owing to the marked swelling, one finger was introduced, and the entire vagina and vaginal portion of the cervix were found to be in the same brawny state. No trace of the tablets was found. No one was present to assist, but realizing the value of time I made a strong soap solution (a gallon), emptied therein the contents of a box of cooking soda and gave her myself a copious vaginal douche; then, using the handle of a bent tablespoon as a Sims speculum, with the patient in knee-chest position, the whites of five eggs were put into the vagina. The swollen labia served to retain the albumin. The white of one egg will neutralize about four grains of bichlorid; therefore the albumin was present in sufficient quantity, though too late, to neutralize most of the bichlorid; it seems likely, however, that the subsequent failure of the vagina to slough was due to the albumin. A hypodermic injection of morphin was given to relieve the intense suffering. Before the morphin was given the patient was beginning to be nauseated, owing, it seemed to me, to the excretion of the bichlorid into the stomach, and so as fast as she would vomit she was made to drink a pint or so of water which in a few moments she would vomit again. The case was then turned over to her family physician, mine having been an emergency call, and I saw the patient no more for seven days.

Examination.—The change in her was pitiful. She had been an unusually pretty woman, but though I had known her for years, I could not have recognized her in the woman before me. The entire, face, neck and chest, for several inches below the clavicles, were tremendously swollen, the eyes practically closed, the tongue so swollen and protruding that the lips were forced far apart. The tongue and buccal mucous membrane were a grayish black, and were sloughing; the teeth were loose enough to have been spit out; the breath emitted a most horrible odor. There was not much flow of saliva at this time. The bowels were moving very frequently, small, bloody, mucopurulent stools; for the passage of each, the patient would jump out of bed, and had done so for a week. Her mind was fairly acute, though she could not articulate because of the swelling. She did not complain of pain in her abdomen, nor was she tender or tympanitic at any time while under my observation. Pulse at this time was 130, temperature 101.5 F.

Treatment.—She had been a very hard patient to manage, so the nurse said, and would not submit to any treatment nor would she try to swallow. She was given a very plain talk about the seriousness of her condition and after that she was more amenable. The following treatment was instituted: By means of a 6-ounce glass syringe with a long slender tip, the buccal cavity was irrigated every hour with the following solutions, in the order named: chlorate of potash, phenol 1 per cent., hydrogen dioxid 25 per cent. Much débris was removed each time; hot wet packs were given every four hours; vaginal irrigations with normal salt solution every twelve hours; rectal irrigations of normal salt solution every four hours. The undiluted white of egg and milk, which the patient was soon able to swallow fairly well, was given by mouth. Phenolphthalein in emulsion (8-grain doses) was given every eight hours.

Clinical Course.—Following this treatment the patient improved for the next twenty-four hours. The foul odor of the breath was much less noticed, the buccal mucous membrane became cleaner-looking, the swelling subsided somewhat, the temperature came down to normal, the pulse to 100, the skin reacted nicely, the bowel movements became more watery, and with less tenesmus, and there seemed to be more urine. The urine was never examined or measured because it was always passed with the stools, and the patient never would submit to the catheter; she would tell the nurse when she voided, however, and that (with the absence of uremic symptoms) was the only guide we had to the amount of urine that was being passed. There was no retention in the bladder. These hopeful symptoms continued for about forty-eight hours, the swelling continued to subside, the pulse retained its good quality; the patient became able to swallow well and drank much water. The morning of the tenth day, however, her condition changed; the pulse grew quick and soft, the skin would not sweat, the secretion of urine seemed to have stopped and she no longer attempted to get up for her bowel movements. Her mind grew cloudy and she began to be drowsy, though she had previously slept very little. After another consultation, she was given strychnin, spartein, digitalin, caffein and sodium benzoate, but nothing seemed to avail. The drowsiness deepened into sleep, the sleep into coma from which she could not be awakened. Death ensued on the eleventh day after the poison was introduced. There were no convulsions, and death seemed to be due to heart failure. No autopsy could be obtained.

I have not been able to find report of such a case. It is hoped that this case may serve as a warning to the woman who is always advising her neighbor how she can "bring herself around."

LINEAR AND SUBPERIOSTEAL FRACTURES OF THE LONG BONES IN CHILDREN

WILLIAM PEARCE COUES, M.D.
Surgeon to the Boston Dispensary
BOSTON

The importance of this class of fractures is largely due to the fact that without a good *x*-ray picture they may remain unrecognized. Children are peculiarly liable to them. The necessity of a skiagraph in all cases of injury which in the past have been regarded as sprains and "bruises over the bone" is so well recognized as hardly to require comment. A skiagraph (two views) should be taken in all cases of injury to the extremities in children, even if a careful clinical examination is negative for fracture. The number of fractures of this class that remain unrecognized through failure to have an *x*-ray must be great, and especially so in the field of general practice, in which sometimes an *x*-ray may not be obtainable. Crepitus, abnormal mobility, and often swelling and ecchymosis may be absent in these cases of linear cracks and subperiosteal fractures in children. Without an *x*-ray a diagnosis can, however, be made in most cases from signs which are generally present, and the overlooking of which leads to error in diagnosis.

Careful examination will reveal very definite and valuable information. Localized tenderness along the seat of fracture is present, but, these fractures sometimes being such small affairs, longer and more careful search for them will have to be made than in ordinary fractures. The tenderness, when found, will always be *increased by the classic test of lateral traction between fixed points above and below the seat of fracture.* In long fissures or linear fractures, rotation will always be painful, and more so than any other movement. The relaxation of etherization will not aid our surgical sense in arriving at a diagnosis in the case of these often small and trivial solutions in the continuity of bones.

Case 1 (Clinic No. 10800).—A girl of 5½ years was seen at the Surgical Clinic, Boston Dispensary, April 27, 1909. The history was as follows: One day before she had fallen off a bed, injuring the right wrist. Examination showed no swelling or ecchymosis, very *little tenderness*, and some disability in using *arm*. Most of what little pain there was on examination the child referred to the wrist. The bony prominences were in perfect relation. There was no deformity, crepitus or abnormal mobility. An *x*-ray of the wrist was negative. Another examination showed slight, but definite tenderness over both bones of the forearm, and rotation of the radius was painful. Another *x*-ray was taken of the forearm and the picture showed a fracture of both bones, one transverse of the radius, and the other a slightly fissured linear fracture of the ulna. Treatment, antero-posterior and internal angular splints. Good functional and anatomic results.

Case 2.—A little girl of about 3 years was seen *after a fall* of a few feet from a chair onto the *right foot*. There was lameness and pain in the *right foot* and ankle. There was no pain or swelling of the leg. Examination of the ankle was negative. A fixation dressing was applied and the child kept off her feet. Pain and immediate disability followed attempts at weight bearing on the right foot. All symptoms, however, were referred to the ankle. A careful examination of the whole tibial region was now made. No swelling, crepitus, or abnormal mobility was found, but an area of considerable tenderness over the tibial crest, which either was not present or had been overlooked at the first examination. The *x*-ray showed a linear fracture of the tibial shaft, a mere "crack" in the bone. There was nothing found wrong with the ankle. Treatment, plaster-of-Paris fixation. Good result.

Case 3 (Clinic No. 8624).—A boy of 13 was seen at the surgical clinic, Boston Dispensary, April 3, 1908. The history was as *follows*: While playing ball at school that morning he had fallen, twisting his left ankle, the weight of the body coming on the ankle. Examination of the ankle was negative. There was no swelling or deformity of the leg, no crepitus or abnormal mobility, or displacement. The only sign present was an area of tenderness along the tibial crest, which was *increased on rotation*. The *x*-ray showed a linear fracture of *the tibia running down subperiosteally* to just above the ankle. Treatment, *plaster-of-Paris fixation, recumbency for a time*. Good anatomic and functional result.

Treatment of these cases should be of the simplest sort that is adequate to *maintain fixation* until union is solid. The result anatomically and functionally should in most cases be perfect.

A rough imitation of a subperiosteal linear fracture may be obtained by painting a small piece of wood—a wooden tongue-depressor answers well—with flexible collodion. After drying, a coating densely adherent to the wood is left, which represents periosteum. The wood is now held in a clamp and pressure exerted on its long axis. *After a certain amount of pressure a linear crack* appears in the wood, but the collodion envelope (periosteum) remains intact. *If* the pressure is increased the collodion envelope (periosteum) is torn through and we *have an ordinary closed fracture.*

CONCLUSION

Definite, localized, and well-marked points of tenderness may be found in most of these cases of linear cracks and subperiosteal fractures in children if long, careful search is made for them. Such findings, with increase of pain on firm pressure and rotation with all the classic signs of fracture absent, generally means a slight linear fracture. A diagnosis can in most cases be made clinically. An anesthetic will not help in the diagnosis of these fractures. An *x*-ray should be taken whenever possible. In all cases of injury in which fractures of this nature are suspected, the bony landmarks are in perfect position, and there is no displacement, *rough manipulation and forcible testing for crepitus are uncalled for and may do harm by increasing the fracture, which, as the position is perfect, we should avoid particularly.*

In these cases children often complain of pain and trouble at a distance from the real seat of fracture. The *x*-ray examination should not be confined to the part complained of, but should include the neighboring long bones as well.

903 Boylston Street.

PROCTOCLYSIS AND A NEW INSTRUMENT

EUEIDAS K. SCOTT, M.D.
BOISE, IDAHO.

Proctoclysis unquestionably offers to the physician and surgeon a valuable means of relieving human suffering and aiding the vital powers to resist and overcome disease.

Of the two methods—continuous flow and drop method—of administering salt solution by way of the bowel, the drop method offers the preferable technic to the physician, and more comfort to and more ready acceptance by the patient.

These objections to the continuous flow method present themselves:

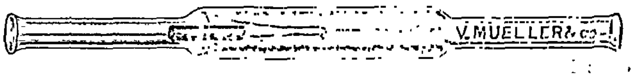
1. Many conditions of rectum, lower bowel and pelvis make pressure of a rectum full of fluid very uncomfortable to the patient and the fluid difficult to retain.

2. Many severe general conditions of patients cause a relaxed sphincter, and thus fluid escapes.

3. The regurgitation of intestinal contents into the apparatus means inconvenience and difficulty in thoroughly sterilizing it.
4. It requires a proper connection and tubing for escape of gases.

These objections are practically overcome by the drop method together with a small glass sight tube and the hard rubber regulator, as shown in the illustration.

The sight tube obviates the necessity of withdrawing the rectal end to note the working of the apparatus. The flow of the liquid can be observed readily without an expensive gauge. Gravity and varying the size and shape of the regulator will regulate the rate of flow from a constant stream to a few drops per minute. A pint and a half of fluid every two hours serves best for general conditions. That means about three drops in two seconds. By timing the rate of drops the amount per hour is noted at once. Back flow into the container is practically eliminated, as the bowel will absorb it at that rate, and there will be no excess unabsorbed.



Hard rubber regulator and glass sight tube for proctoclysis.

Gases can readily escape through the apparatus when the sight tube and regulator are used. The apparatus does not become contaminated with the contents of the bowel.

Patients have almost perfect ease and comfort with this method—a point of no trivial concern to the medical man. The results are more definite and uniform, as a constant, perfect working apparatus is assured and, combined with an irrigating thermometer, is undoubtedly a most valuable contrivance for proctoclysis.

AN UNUSUAL PRODROMAL MANIFESTATION OF IDIOPATHIC EPILEPSY

ALFRED GORDON, M.D.
PHILADELPHIA

Aura preceding an epileptic discharge may be motor, sensory, psychic, or psychomotor. Among the various well-known psychic "warnings" of an oncoming seizure the one here described presents such rare features that its placing on record is warranted.

A boy of 12, suffering from essential epilepsy since the age of two and being affected at irregular intervals with attacks of grand mal and petit mal, began to develop an unusual aura preceding the major seizures. Two days before a fit occurs he becomes exceedingly restless, although he is habitually morose, quiet and of a pessimistic disposition. The restlessness is followed by a desire to embrace and kiss any one who enters the house.

He spends his time in ceaselessly throwing his arms around the neck of every person in the house, be it relative, stranger, or servant in the kitchen. The embrace is accompanied by rough kissing in which he repeats the act a great many times and ends with biting the kissed spot of the face. The kissing is only interrupted by eating and sleeping. But as soon as he is done eating or wakes up after a sleep he resumes his peculiar occupation. He does not hesitate in doing so while on the street, and for this reason he is kept strictly in the house until the attack of epilepsy has passed.

The act of kissing is sometimes replaced by the act of laughing. The laughter is then unusually loud and unusually long and, according to his mother, it lasts sometimes five minutes. No measure employed at that time to arrest the "enervating" act is of any avail. He must go on and not be interrupted. As soon as he is done laughing he resumes his act of embracing. Curiously enough, the laughing, embracing and kissing, in spite of being prolonged and almost without intervals, do not apparently exhaust the patient. At the time of his meals his restlessness ceases and at 7 o'clock in the evening he asks to be put to bed.

During the forty-eight hours of this unusual activity the boy realizes the situation and is well aware of his acts. He converses rationally, answers questions, but when asked to cease his actions, he claims that he makes efforts, but is hopelessly incapable to arrest them. He "must go on," "something forces" him to do so, he says. His mother also states that sometimes (not in each attack) the kissing is substituted by striking or slapping. He seizes every person in the house and strikes them several times in succession with his open hand over the back or else over the face. His little brothers or sisters are the usual victims of this performance.

It is also interesting to observe that during the time he is indulging in the peculiar propensities mentioned, his appetite is extremely great so that no amount of food can satisfy him, and he excretes an unusual quantity of urine with a remarkable frequency (almost every half hour).

The unusual psychomotor manifestations described above last forty hours, after which he suddenly falls unconscious and goes through all the phases of a genuine major attack of epilepsy, viz., tonic and clonic convulsions, frothing at the mouth, biting of the tongue. An attack is followed by a profound sleep. After he regains consciousness and the habitual mental hebetude disappears he is able to recall the peculiar prodromal phenomena. He feels much embarrassed for his singular behavior, for embracing and kissing so profusely strangers and relatives. He then becomes depressed for a period of five or six days.

The prodromal manifestations described made their first appearance only at the age of nine and they appear only before an epileptic seizure. The latter occur irregularly, but not more frequently than once in three or four months. The appearance of the peculiar phenomena which never fail before a fit—and especially their regularity—is an excellent warning for the patient's relatives so that they are able to take the necessary precautions to avoid accidents.

The interesting part of this observation lies in the manifestations of the unusual symptoms preceding an epileptic convulsion, *viz.,* in the exaltation of physical and mental functions, in the regularity of the prodromal manifestations and, finally, in the fact that the latter were accompanied apparently by a complete lucidity of mind, but by a complete inability to control them on the patient's part. The actions were automatic, uncontrollable, impulsive.

Can such actions be considered conscious? Although the patient was able to answer questions and, according to the mother, knew what he was doing, nevertheless the automatic acts could hardly be considered conscious. The automatic nature of the acts preclude voluntary efforts and therefore they are unconscious or subconscious.

Extreme restlessness with exaltation of all functions with apparent lucidity of mind are characteristic of the maniacal phase of manic-depressive insanity.

Was the condition in the present case an analogous occurrence?

Could the singular manifestations preceding the major attacks of epilepsy be considered as attacks of *petit mal?* I am inclined to accept the latter view.

1430 Pine Street.

THREE CASES OF INFECTION WITH THE DWARF TAPEWORM (HYMENOLEPIS NANA) IN CHILDREN

OSCAR M. SCHLOSS, M.D.
NEW YORK

During the past eighteen months I have encountered 20 cases of infection with the dwarf tapeworm in children, 14 of which have been reported in a previous paper.[1] Three of the six additional cases encountered present points of sufficient interest to warrant an additional report.

Since the paper of Stiles[2] in 1903, a number of cases of infection with *Hymenolepis nana* have been reported in this country. Stiles predicted that the dwarf tapeworm was going to prove a common American parasite, and from my experience it is one of the commonest intestinal worms in children.

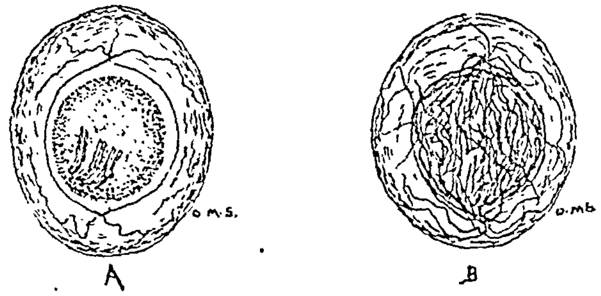

Fig. 1.—Ova of *Hymenolepis nana, greatly* enlarged; A, showing embryo; B, superficial focus showing filaments.

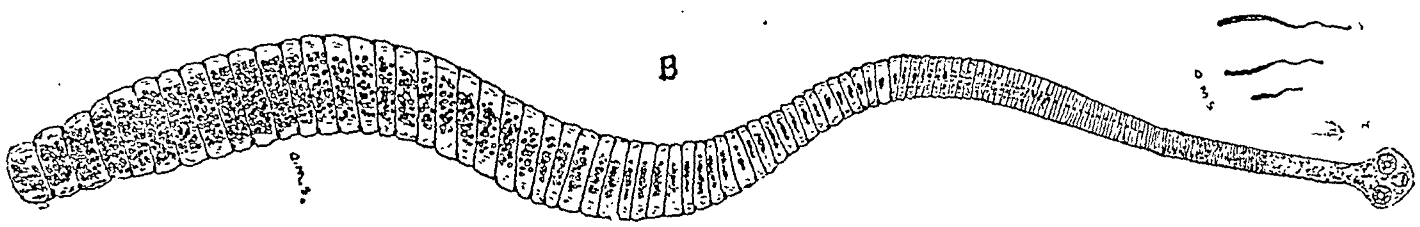

Fig. 2.—*Hymenolepis nana;* A, actual size; B, enlarged.

The dwarf tapeworm is the smallest cestode parasite of man, and great numbers of the worms are usually present in the infected cases. In the cases in which I have been able to make an estimate, the number of worms passed after treatment has ranged from 50 to over 2,000.

The presence of this parasite is indicated by the occurrence of the characteristic ova in the feces. The ova are usually colorless, though they may assume a slight brownish tint when they have stood in contact with the feces for some time. They have a slightly oval outline and are easily seen with the low power of the microscope (Leitz objective No. 3 or an equivalent). The eggs have two distinct membranes and within the inner is the embryo, which contains six booklets. The inner membrane has a slight projection at each pole, from which delicate filaments arise and ramify in the space between the membranes.

It is beyond the scope of this paper to attempt a description of the parasite, but the reader is referred to the text-books on helminthology or to the references given.[3]

CASE REPORTS

Case 1.—*Patient.*—P. G., male, aged 3½; born in New York City; Italian parentage. There was nothing important in the past history. The patient had not been entirely well for over a year. He had become pale and listless, though there was no apparent loss of weight. He was restless during sleep and frequently cried out during the night. The appetite was poor, the bowels constipated. The patient suffered from frequent attacks of abdominal pain which was referred to the epigastrium. The pain was of moderate severity and for several months two or three attacks had occurred each day.

Examination.—This showed a pale, fairly well-nourished child who did not appear acutely ill. The temperature, pulse and respirations were normal. The mucous membranes were pale and there was slight puffiness beneath the lower eyelids. The physical examination was otherwise negative. The feces contained numerous ova of *Hymenolepis nana.* The hemoglobin was 55 per cent. (Sahli hemometer) and the number of red blood cells was 3,900,000 per cubic mm. A differential count of 500 white cells gave the following percentages: Polynuclear cells 26.8 per cent., lymphocytes, 45.6 per cent., large mononuclear and transitional cells 16 per cent., eosinophil cells 10.9 per cent., basophil (mast) cells 0.2 per cent.

Treatment and Course of Disease.[4]—The usual treatment was given and numerous dwarf tapeworms were passed. Two thousand worms were counted but there were easily twice this number. Twenty days later the feces contained no ova. The child has shown great improvement. There has been no recurrence of the abdominal pain and sleep is normal. The patient is still (six weeks after treatment) rather pale.

Case 2.—*Patient.*—W. W., male, aged 5; was born in New York City of Irish parentage. The past history was negative. Two months before admission the patient began to lose weight and to be pale and irritable. He slept poorly and would frequently awake and cry out during the night. He had suffered from attacks of abdominal pain for about five weeks. The pain was referred to the epigastrium and would often occur several times a day. These symptoms remained the same until three weeks before admission when the patient had a general convulsion. All four extremities were affected; the convulsive attack lasted about three minutes and was followed by unconsciousness for about fifteen minutes. Similar convulsive attacks occurred two weeks and one week before admission.

Examination.—The child was moderately well nourished, with slightly pale skin and mucous membranes. With the exception of adenoid and tonsillar hypertrophy there were no abnormal physical signs. The hemoglobin was 70 per cent. (Tallquist scale) and a differential count of 500 leucocytes as follows: Polynuclear cells 45 per cent., lymphocytes 40.3 per cent., large mononuclear and transitional cells 7.6 per cent., eosinophils 7 per cent. A moderate number of the ova of *Hymenolepis nana* were found in the feces.

Treatment and Course of Disease.—The routine treatment was given. About 300 dwarf tapeworms were expelled and twenty days later no ova could be demonstrated in the feces. There has been no recurrence of the convulsions and the other symptoms have disappeared (one month after treatment). The mucous membranes are still slightly pale.

Case 3.—*Patient.*—C. G., male, aged 6; born in New York City. This patient is a brother of Patient 1. The symptoms in this case were almost identical with those in Case 1. The attacks of epigastric pain were less frequent and not so severe. The appetite was poor, the bowels constipated.

---

[1] Archives of Pediatrics, February, 1910.

[2] Stiles: New York Med. Jour., 1903, lxviii, 877.

[3] For a complete description of the parasite and a review of the literature, see Ransom, Bull. 18, Hyg. Lab. U. S. P. H. and M.-H. S., 1904.

[4] The treatment used in these cases was that usually followed in the case of the larger tapeworms. Oleoresin of malefern was used and was given in three to five doses. One half to one dram is usually sufficient and has, in my experience, been without ill effects. A single treatment is not always sufficient. It is possible that the heads of some of the parasites are left in the intestine, or parasites in embryonic stages may be present, which are unaffected by the treatment.

Examination.—The hemoglobin was 60 per cent. (Sahli hemometer). Five hundred leucocytes were counted and were in the following percentages: Polynuclear cells 49.9 per cent., lymphocytes 22.5 per cent., large mononuclear and transitional cells 13.8 per cent., eosinophils 13 per cent., basophils 0.4 per cent.

Treatment and Course of Disease.—Three hundred dwarf tapeworms were expelled by treatment. The feces were examined twenty days after treatment and no ova were found. A second examination thirty-six days later was also negative. The symptoms were relieved by treatment and up to the present time have not recurred.

In many instances the dwarf tapeworm seems to be entirely harmless, judging from the absence of symptoms. In other cases symptoms are present which are usually mild, but in certain instances are rather severe. The three reported cases showed symptoms of unusual severity and give sufficient evidence that in a few cases at least the dwarf tapeworm may give rise to obscure gastro-intestinal or nervous disorders.

These cases were from the service of Dr. Eli Long in the pediatric clinic of the New York University and Bellevue Hospital Medical College. I desire to acknowledge my indebtedness for the privilege of making this report. I also wish to thank Miss Eleanor Ketcham for valuable assistance in carrying out the treatment and in following the cases.

54 West One Hundred and Fourth Street.

RUPTURE OF THE URINARY BLADDER OPERATED ON SEVENTY-SEVEN HOURS AFTER INJURY

JAMES R. JUDD, M.D.
HONOLULU, H. I.

With the literature at my disposal, I was under the impression that this was a very unusual case in respect to the interval of time between the injury and the laparotomy. In von Bergmann's surgery, vol. v, a case of Roses is recorded in which the patient was operated on 48 hours after the injury, and this is considered as probably the longest interval of time on record followed by a successful outcome. Quick,[1] however, reported an extraordinary case of 254 hours' interval. In this case the patient was able to void some urine, and the rupture "admitted the thumb rather tightly." The same article mentions Blumer's patient, operated on on the sixth day, and Alexander's case with 90 hours' interval. While the above reported cases render mine not unique, there is enough of interest to make it worth reporting.

History.—The patient, a native Hawaiian, aged 55, after a debauch fell off a veranda, a height of about six feet, and struck his abdomen. He immediately felt a sensation of something giving away inside of him and was unable to void any urine. He suffered considerable pain in the bladder region, and noticed that the abdomen began to swell. From Thursday, August 12, at 7 a. m., until Sunday, August 15, at 1 p. m., when he was brought to the hospital, he had passed no urine, the distention of the abdomen had increased, and respiration was becoming embarrassed.

Examination.—This showed a thin, sickly-looking adult, who lay on his back with his legs flexed. The pulse was 120 and feeble; respiration was 40 and labored, and temperature was 98. The abdomen was very much distended and the skin tense. There were no visible signs of injury. There was tenderness over the entire abdomen and the percussion note was dull. A catheter drew off a few drops of clear urine.

Operation.—Operation was performed at once. On opening the peritoneum, a jet of urine shot up to a height of about four feet. The amount of urine free in the abdominal cavity was estimated at six quarts. The posterior wall of the bladder showed a transverse rent with ragged edges, easily admitting four fingers. The peritoneum was everywhere injected but there was no evidence of peritonitis. The edges of the bladder rent were freshened and the wound sutured by a plain catgut through-and-through continuous suture including all the coats, followed by a Dupuytren silk suture for the peritoneal coat. The abdominal cavity was flushed out with salt solution and the parietal peritoneum sutured without drainage. The bladder was drained as in a suprapubic cystostomy. The abdominal wall was then closed, allowing exit for the tube.

Result.—The patient was placed in the Fowler position and did well for four days, when he began to show symptoms of delirium tremens and, when he was not being watched, he disconnected the tube and made his exit from the hospital. He was found after having walked about 200 yards and was put back to bed. The next day, in his delirium, he pulled the tube out of the wound, causing severe hemorrhage. A catheter was then placed in the urethra and the urine drained partly through the catheter and partly through the suprapubic wound. From that time on recovery was uneventful. The catheter was removed in five days and the patient began to pass urine successfully. There was at no time any evidence of cystitis. The man was out of bed in two weeks with a granulating wound which in two weeks more had entirely closed.

POLYCYTHEMIA DISAPPEARING AFTER REMOVAL OF THE APPENDIX

BAYARD HOLMES, M.D.
CHICAGO

Polycythemia, so often overlooked in routine examinations of the blood, must be considered a master symptom. It is not an anhydremia but a plethora, probably of toxic origin. It is directly due to an increased activity of the hematopoietic function of the bone-marrow as the histology shows at autopsy.[1] The fact that the polycythemia is so obvious (6,000,000 or more), is due to the effort of all the organs to dispose of the increased volume without raising the blood-pressure. Boycott and Douglas[2] demonstrated in 9 cases of polycythemia that the volume of blood was two or three times the normal, thus resembling chlorosis, ankylostomiasis and pernicious anemia. Thus the plethora of the ancients is restored to us in a new light.

The close relation between methemoglobinemia and polycythemia is so intimate as to make us associate them in searching for their etiology. In half of all the cases of sulphmethemoglobinemia and methemoglobinemia the patients have had a true polycythemia.[3]

The uncertain origin of polycythemia leads me to report the following case:

History.—E. J., aged 21, came to me with the diagnosis of appendicitis. He was a tall brunette and weighed 128 pounds. His father died at 57 of some abdominal disease, possibly cholangeitis. His two brothers are well and resemble him and their mother strongly, except in size. In that particular they resemble their father. While in school he became weak, dizzy and nervous, so that he could not rely on himself to do his work. He persisted for a few months, however, and then in 1908 went home. He was troubled with both diarrhea and constipation and was treated for mucous colitis. He made some improvement under the prescribed diet and the mucus disappeared but the attacks of general and abdominal distress continued. One of these spells was attended by so much tenderness over the region of the apendix that the patient's physician recommended the removal of the appendix.

[3] For bibliography see Quart. Jour. Med., 1909, ii, 128.

Examination.—The history was so much like a severe toxemia that I doubted the diagnosis for a time. The cerebral and neurasthenic symptoms, with abdominal discomfort, made me think of a long line of the diseases of uncertain origin. The examination of the blood which was made in my office, at Wesley Hospital and in the laboratory of the Northwestern University showed a high grade of polycythemia, 7,750,000 on the average. Many blood examinations were made by various observers and all agreed in a high red count without abnormality in white elements. The blood-pressure varied between 130 and 160 at various times. No spectroscopic examination of the blood was made as I did not at that time recognize the possibility of a methemoglobinemia. As I remember the patient now he did not show any cyanosis, or have any clubbing of the fingers. His spleen was not noticeably enlarged.

Operation.—In spite of my misgivings and with full understanding of the situation by the patient, his friends and his physician, I removed the appendix in July, 1909. There was evidence of a chronic appendicitis but unfortunately no examination of the colon or intestines was made through the small opening. There was no lymphadenitis such as we find in typhoid and no tuberculous peritonitis.

Postoperative History.—During the week in the hospital after the operation there was no change in the blood-count. On the patient's returning home he was advised to take the outdoor and forced feeding treatment, and a buttermilk and sauerkraut diet was especially urged. In September the blood was found entirely normal by Dr. Schooler of Pontiac. In February the patient called and seemed much improved in general appearance. He weighed 147 pounds. His blood was entirely normal, 4,800,000 reds, 7,500 leucocytes in normal proportions.

The possible relation between colon bacillus infection and polycythemia makes this observation, which seems to me unique, worthy of record.

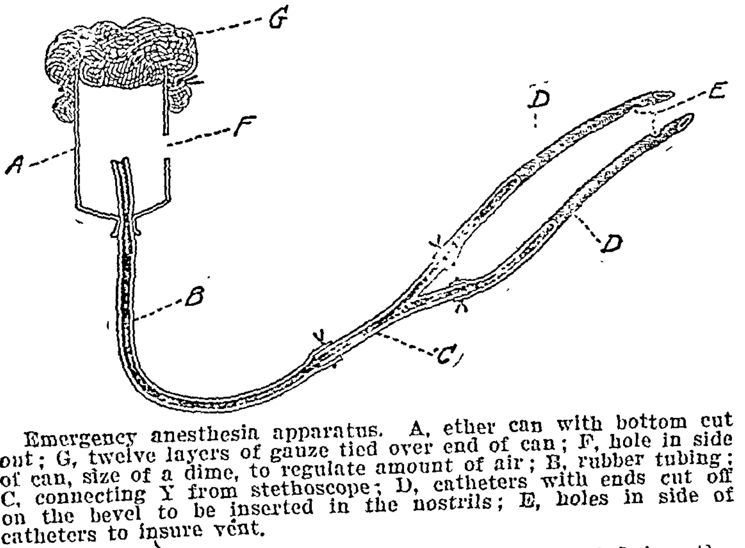
AN EMERGENCY APPARATUS FOR ADMINISTERING AN ANESTHETIC

GEORGE A. CATHEY, M.D.

PORTLAND, ORE.

One morning a man was brought into the surgery of the Good Samaritan Hospital with the right side of his face badly lacerated, requiring an operation. The anesthetic was started, and while the patient was being scrubbed the surgeons realized the difficulty of doing the operation with the ordinary inhaler constantly in the way. Within five minutes I devised and had ready for operation the apparatus shown in the illustration.



Emergency anesthesia apparatus. A, ether can with bottom cut out; G, twelve layers of gauze tied over end of can; F, hole in side of can, size of a dime, to regulate amount of air; B, rubber tubing; C, connecting Y from stethoscope; D, catheters with ends cut off on the bevel to be inserted in the nostrils; E, holes in side of catheters to insure vent.

The tubes were introduced into the nostrils, the anesthetic was continued, and the operation finished without interference from administration of the anesthetic.

New and Nonofficial Remedies

Since the publication of the book "New and Nonofficial Remedies, 1910," the following articles have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association. Their acceptance has been based largely on evidence supplied by the manufacturer or his agent and in part on investigation made by or under the direction of the Council. Criticisms and corrections to aid in the revision of the matter before publication in the book are asked for.

The Council desires physicians to understand that the acceptance of an article does not necessarily mean a recommendation, but that so far as known it complies with the rules adopted by the Council.

W. A. PUCKNER, Secretary.

(*Continued from page 1142*)

THIOL.—Thiolum.—Thiol is a water soluble mixture of sulphurated and sulphonated petroleum oils.

Thiol is prepared by heating certain paraffin oils with 10 per cent. of sulphur, by which a partial addition of the sulphur takes place. *The thiol oil thus formed is then treated with sulphuric* acid for sulphonization. The excess of sulphuric acid is washed out by water and the sulphonated product neutralized by ammonia and the solution freed by dialysis from all inorganic salts. The dialyzed product evaporated to dryness contains about 12 per cent. of sulphur. For therapeutic purposes the evaporation is not carried to absolute dryness but the product is marketed either in the form of a syrupy liquid (Thiol Liquid, see below) or as a powder (Thiol Dry, see below).

Thiolum is a brown powder with a pleasant odor resembling Russia leather, having a somewhat bitter and slightly astringent taste. It swells up in water and finally dissolves. It is also soluble in alcohol and slightly soluble in ether.

Thiol should not markedly redden litmus paper.

Actions and Uses.—Thiol is said to have a drying, astringent, antiphlogistic, and disinfecting action. Taken internally it is said to favor digestion and defecation. It is said to be useful in skin diseases, especially in dermatitis, acne, eczema, erysipelas, erythema, furunculosis, herpes, pruritus, pityriasis, etc. It is also claimed to be useful in burns, in rheumatism and in certain diseases of women.

Dosage.—It may be applied locally in the form of liquid thiol in full strength or in solution with glycerin or water or in the form of ointment or a 2 per cent. solution of liquid thiol may be used as a spray. Internally it may be given in the form of dry thiol in the dose of 0.1 to 0.2 Gm. (1½ to 3 grains) three times a day. Dry thiol may be employed as a dusting powder, either alone or with 80 per cent. of starch or in the form of ointment or of paste.

Manufactured by J. D. Riedel Aktiengesellschaft, Berlin, Germany (Riedel & Co., New York). U. S. trademark 16,553.

Thiol Dry.—Thiolum Siccum.—Thiol Dry is a brown powder with properties corresponding to the description of thiol, containing from 8 to 9 per cent. of sulphur.

Actions, Usage and Dosage.—See Thiol.

Thiol Liquid.—Thiolum Liquidum.—Thiol liquid is a preparation of thiol containing about 1.8 to 2 per cent. of sulphur.

It is a dark brown neutral liquid of a not unpleasant smell resembling that of *Russian leather. It is easily* soluble in water and glycerin but only slightly soluble in ether.

Actions, Uses and Dosage.—See Thiol.

ARTICLES ACCEPTED FOR N. N. R. APPENDIX

The Maltine Company, Brooklyn, N. Y

Maltine[1] *with Cascara Sagrada.*—Each 100 Cc. is said to represent cascara sagrada (Rhamnus Purshiana) 12.5 Gm. (60 grains in a fluidounce) in a mixture containing maltine 96.115 per cent. and alcohol 3.885 per cent.

Maltine with Cod Liver Oil.—A liquid said to represent maltine, 56,115 per cent.; glycerin, 10 per cent.; cod liver oil, 30 per cent.; alcohol, 3.885 per cent.

Maltine with Creosote.—Each 100 Cc. is said to represent beechwood creosote, 0.83 Cc. (4 minims in a fluidounce) in a mixture containing maltine, 96.115 per cent., and alcohol, 3.885 *per cent.*

Maltine Ferrated.—Each 100 Cc. is said to represent iron pyrophosphate 1.65 Gm. (8 grains in a fluidounce) in a menstruum containing maltine, 96.115 per cent., and alcohol, 3.885 per cent.

Maltin [illegible] —Each 100 Cc. is said to contain calcium [illegible] (3 grains in a fluidounce), sodium hypophos[illegible] ns [illegible], and iron hypophosphite, 0.42 Gm. (2 grains in a [illegible] in a solution of ammonium citrate and to contain [illegible], [illegible] per cent., and alcohol, 3.885 per cent.

Maltine with Olive Oil and Hypophosphites.—A preparation said to consist of maltine, 65 per cent.; pure olive oil, 25 *per cent.*; glycerin, 10 per cent.; to which per 100 Cc. there is added calcium

---

1. Maltine plain is already in N. N. R. Appendix, which see.

hypophosphite, 0.6 Gm. (3 grains per fluidounce); sodium hypophosphite, 0.6 Gm. (3 grains per fluidounce).

Maltine with Phosphate of Iron, Quinia and Strychnia.—Each 100 Cc. is said to represent iron pyrophosphate, 0.83 Gm. (4 grains in a fluidounce); quinine sulphate, 0.21 Gm. (1 grain in a fluidounce); strychnine (alkaloid), 0.0066 Gm. (2/75 grain in a fluidounce) dissolved in a solution of ammonium citrate and to contain maltine, 96.115 per cent., and alcohol, 3.885 per cent.

Maltine with Wine of Pepsin.—A liquid said to consist of maltine, 27.5 per cent.; wine of pepsin, 71.5 per cent.; and fluid extract of gentian, 1 per cent., the percentage of alcohol in the mixture being 18 per cent.

Malto-Yerbine.—A liquid said to contain in each 100 Cc. an extract of 6.6 Gm. (30 grains in a fluidounce) of eriodictyon (Yerba Santa), also flavoring composed of the essential oils of anise, cassia, coriander and caraway in a mixture containing maltine, 96.115 per cent. and alcohol, 3.885 per cent.

The extract of Yerba Santa employed in Malto-Yerbine is prepared as follows:

The leaves of Yerba Santa in coarse powder are boiled under pressure for six hours and inert matter separated by a filter press. The filtrate is concentrated with a certain quantity of maltine at a high temperature until the product has reached a density of 1.35 This extract is mixed in proper proportions with maltine of extra diastasic strength to make up for the diastasic strength lost through heat during the concentration of the drug with maltine.

(*To be continued*)

Therapeutics

TUBERCULOSIS

Any suggestion that even apparently tends to the successful treatment of this disease is worthy of general consideration, and the careful observations of Dr. John F. Russell, of New York, should not be allowed to pass by without comment. In the *Medical Record* of Nov. 27, 1909, and Dec. 18, 1909, he discusses his observations on the value of lime to the nutrition and its apparent ability to aid in Nature's healing of pulmonary tuberculous lesions.

He calls to mind that lime forms three-fourths of the total mineral salts of the body, and that it is found in all tissues and fluids, and that the most important lime salt is the insoluble phosphate. The chief lime-carrying food is milk, and, next to it, eggs, and it is certainly conceded that milk and eggs are most important in the diet of a tuberculous patient. It seems to be a chemical fact that the phosphate of lime is most ready for absorption and nutrition when it is in chemical union with a proteid. Whether a lack of lime is a predisposing cause of the successful growth of tubercle bacilli, as apparently believed by Russell, he seems to have shown that the more lime that is presented to these patients in a manner in which it can be absorbed and assimilated the more likely are they to improve and the more rapid is their, at least temporary, recovery. He has noticed, that when natural lime is presented in such a manner that patients will absorb it, that an effusion and symptoms of acute pleurisy occur over the region of lung that is diseased. The patients have increased temperature and pain, and all the signs of a plastic pleurisy. These symptoms last for a week or more, and, he says, as a rule the more marked the lung lesion the more marked the physical signs of pleurisy. After these acute symptoms subside and the slight effusion begins to organize, he finds that local improvement in the diseased lung can soon be determined. The time at which these symptoms of pleurisy develop is from the sixth to the sixteenth week after the treatment is begun.

Russell finds that the best method of administering the phosphate of lime, so that the patient may assimilate it, is by causing its combination with casein by acidifying milk with dilute hydrochloric acid. He says this cannot be well done by administering the acid after the patient has drunk milk, but a combination of egg and milk previously prepared makes, in his estimation, a successful lime food. "Two eggs are beaten, strained and mixed with enough milk to make a quart. Then 4 fluidrams (16 c.c.) of dilute hydrochloric acid are added to the mixture and stirred until thoroughly mixed. The mixture is then bottled and placed in an ice chest, and the patient drinks a pint in the morning and a pint in the evening. The size of the curds in the milk varies with the temperature of the milk at the time when the acid is added; the warmer the milk the thicker the curds, but they are always soft and easy to digest. The taste of this combination is not unpleasant."

Russell explains the action of the hydrochloric acid as, "first, to activate rennet zymogen; second, to activate pepsin zymogen; third, to stimulate the secretion of the pancreatic juice" by the promotion of the production of secretin from the intestinal glands, which hydrochloric acid has the power to do.

Russell insists that a patient is not successfully treated unless he gains weight up to the standard that was his previous normal. Russell does not strive to increase the patient's weight after he has attained his normal.

As noticed in other feverish processes, when there is fever in tuberculosis, probably the hydrochloric acid of the stomach is diminished in amount. Also, it is a fact that an increased amount of milk or increased amount of fats, as so generally ordered and prescribed in tuberculosis, will inhibit the normal output of hydrochloric acid. Both of these facts make it physiologically correct to administer dilute hydrochloric acid.

Russell does not presume that the increased amount of lime which he aims to have his patients assimilate will act as a poison to the tubercle bacillus, but he claims that when there is lime starvation or insufficient lime in the tissues that the cells do not properly function, and if lime in normal amount reaches the blood it will restore the normal protective function of the cells in producing a fibrosis at the point of irritation caused by the growth of the bacillus. His choice of the casein method of increasing the lime is because it has a peculiar affinity for lime salts, particularly the phosphate, and combines with them chemically. The investigations to which he refers also show that in the absence of rennet the chemical combination of lime and casein will not take place, and the rennet zymogen of the stomach will not act if there is not free acid present. Consequently, Russell has devised his method of increasing the absorption of lime on a scientific basis.

In further elaborating his theory that lime starvation may predispose to the growth of the tuberculous process, he instances the fact that pregnancy and lactation, with its drain on the mother's lime salts, and prolonged fever with the consequent diminished nutrition from the diminished amount or absence of normal hydrochloric acid in the stomach, all predispose to tuberculosis.

A tendency to repeated attacks of hemoptysis and other hemorrhages is now generally conceded to be due to lack of the proper amount of lime in the blood. Also, tuberculous processes that are healing require an extra amount of lime. All of these conditions, then, seem to show that an extra amount of lime is needed in tuberculosis.

Another interesting fact pointed out by Russell in this discussion of lime starvation is that cows are much more likely to be affected with tuberculosis than are bulls or calves, and, of course, it is the cow that is losing a large amount of lime with her milk; i. e., it would take more lime in a properly assimilable form to keep the lime content of her tissues normal than in the calf or the bull. Therefore, this dietetic suggestion of Russell's for tuberculous patients is worthy of practical application.

THE AMERICAN MEDICAL ASSOCIATION—ITS POLICIES AND ITS WORK

V. THE COUNCIL ON PHARMACY AND CHEMISTRY

In this series of editorials dealing with the work of the American Medical Association it is, in the nature of the case, impossible to prevent repetition. The work of the Association is so far-reaching and ramifies in so many directions that no one phase can be considered except in its relation to others. For example, it is impossible to discuss the work of the Council on Pharmacy and Chemistry without touching on the relation of the medical press to the proprietary question; neither is it feasible to deal with the work of the Association laboratory without dwelling to some extent on the "patent medicine" evil. We make no apology, therefore, for saying some things more than once. Reiteration of facts can do no harm; probably it is what is needed.

The organization of the Council on Pharmacy and Chemistry and the publication in The Journal of the work accomplished by the Council have made more enemies for the Association and its journal than all other activities of the Association combined. When it is realized that millions of capital were and are invested in the manufacture of fraudulent proprietaries and that a large portion of the medical press was and is deriving its existence directly or indirectly from the proprietary interests, it is not surprising that the most strenuous opposition arose when the Council undertook to tell the medical profession the truth about therapeutic frauds.

The cheap newspapers have consistently defended the "patent medicine" humbugs; for the same reasons the poorer class of medical journals have fought the work of the Council; not openly, except at first, for that would be impolitic, but by attacking the Association and by attempting to discredit its officers. It is a demonstrable fact that, SHOULD THOSE PREPARATIONS WHICH THE COUNCIL HAS SHOWN TO BE FRAUDS CEASE TO BE ADVERTISED, ONE-THIRD OF THE MEDICAL JOURNALS IN THE UNITED STATES WOULD GO OUT OF EXISTENCE.

It is unnecessary again to give in detail the reasons which brought the Council into being. The disgraceful condition into which drug therapy in the United States had sunk; the shameless impositions practiced on the public and the medical profession by proprietary frauds; the brazen way in which men without knowledge of medicine or pharmacy assumed to teach physicians how to treat disease; the subordination of the medical press to the nostrum interests—these were but some of the grosser abuses which had resulted from the unrestricted manufacture and sale of proprietary remedies. These evils the Association, through its Council on Pharmacy and Chemistry, hoped to correct; and these evils it has been, and still is, correcting with a success that is plain to all those who have taken even a superficial interest in the questions involved, and is even more clearly evidenced by the nature of the opposition it has aroused. In its work the Council has received the aid and approval of men—in both the United States and Europe—who rank among the highest in their professions, a cooperation that has meant much to the medical profession of this country.

Neither is it necessary to enlarge on the aims and objects of the Council; with these the medical profession, by this time, is thoroughly conversant. Moreover, this phase of the subject was exhaustively discussed by Professor Sollmann in his series of articles on "The Broader Aims of the Council." It is more important that physicians generally, and members of the organization especially, should be brought to a realization of what the Council on Pharmacy and Chemistry has actually done in the five years of its existence.

Proprietary products submitted to the Council are not hastily or superficially examined, but to each the most painstaking and careful consideration is given. Notwithstanding this, the Council has critically examined and thoroughly considered the claims made for more than one thousand products, of which over six hundred[1] have been accepted for inclusion in "New and Nonofficial Remedies," while nearly four hundred have been rejected. There are, of course, hundreds of nostrums which on their face are so plainly fraudulent that no intelligent physician could be misled by them and to which, since they stand self-condemned, the Council has not attempted to give more than a superficial examination. It is impossible for one not conversant with the details to realize the amount of work these figures represent. Nor does the examination of proprietary products which the manufacturers themselves have submitted comprise nearly all the labors of the Council. A large number of widely advertised preparations for which specious claims are made have been taken up on the Council's own initiative and their viciousness made plain to the medical profession.

---

[1] It should be said that at the time the Council was organized probably not one-half of these six hundred preparations conformed with the Council's requirements. An honest desire on the part of the manufacturers to better the status of therapeutics caused them to modify their claims and made the acceptance of these products possible.

In addition to the vast amount of work that has been done on proprietary products, a number of drugs that are neither proprietary nor official have been considered by the Council. Such of these products as seem to have some therapeutic virtue have been described in "New and Nonofficial Remedies," while descriptive and critical reports have been published on those that are without proved value and whose deletion from the already overburdened materia medica would be desirable.

One phase of the work that at first was merely incidental to the general duties of the Council finally became of sufficient importance to warrant a special report, namely, that of curbing to some extent the misquoting of medical literature by proprietary manufacturers for their own ends. So extensive had this abuse become that even the more conservative manufacturers were guilty of grossly misrepresenting the views of medical writers. The Council took up one glaring instance and published an extensive report on the subject. The value of the preparation itself was not discussed, the only question being that of the garbling and misquoting of contemporary medical literature dealing with the preparation. That this report, together with the careful scrutiny to which the Council subjects the advertising matter of all preparations which it considers, has done much to cause manufacturers to be more conservative and truthful in praising their products and in quoting literature, is evident to any one who cares to compare the advertising "literature" of to-day with that issued five years ago.

Physicians, with the laity, have long held exaggerated views regarding the food-value of meat-extracts, though it has been proved, time and again, that, aside from possessing mildly stimulating properties, they are practically valueless. Moreover, while meat-*juices* have a distinct food value, many so-called meat-juices on the market are practically meat-extracts. The Council published the results of a most exhaustive chemical examination of some of the most widely advertised preparations for which great nutritive value was claimed and its practical absence was proved.

Within the past year the Council has devoted some time and work to the consideration of serums and vaccines, and through its initiative a symposium on these subjects was presented to the Section on Pharmacology, in which the best authorities in the United States were represented. From the conclusions reached by these authorities the Council prepared descriptions of the various products found on the American market.

In brief, then, it may be said that the Council has examined practically every proprietary article of any value now on the market, and that those which have not been accepted are unworthy of the physician's consideration.

It has shown up the fraud, misrepresentation and deceit connected with the exploitation of many of those proprietary articles which were a disgrace to pharmacy, a detriment to scientific medicine and a danger to the public.

It has—by insisting that products to be acceptable shall be advertised truthfully—done more to raise the commercial ethics of pharmaceutical manufacturers than any other agency—not even excepting the national Food and Drugs Act.

It has made plain, in a manner never before attempted, the strictly limited value of many largely advertised "meat-juices."

It has furnished the profession with information regarding the value of numerous unofficial, non-proprietary drugs and has thereby done much to dispose of the useless lumber of the overloaded materia medica.

It has thrown light on that valuable and ever widening branch of therapeutics, serum therapy, and, so far as our present knowledge will permit, has separated the wheat from the chaff.

It has, in fact, at all times tried to make plain to the medical profession the vast possibilities of rational, sane and scientific drug therapy as contrasted with the haphazard and vicious results of nostrum-prescribing. It has consistently, persistently and insistently told the truth about proprietaries—good, bad and indifferent—without fear or favor.

Therapeutics in the United States has progressed more in the last five years than it did in the previous fifty—and the Council is responsible for it. The American physician has a clearer conception of the possibilities and limitations of drugs to-day than he ever had before—and the Council is responsible for it. Purer and more reliable pharmaceuticals can be had now than ever before was possible—and the Council has been largely responsible for it. The reading pages of medical journals now published are freer from nostrum testimonials disguised as original articles than has been the case for a quarter of a century—and again the Council is responsible for it.

This work has not been accomplished without arousing the most active antagonism of those nostrum manufacturers whose products were exposed and of those medical journals whose existence depends on the advertising receipts from such manufacturers. When millions are invested in perpetuating a profitable fraud there can always be found those who will seek to justify the dishonesty—and the nostrum business is no exception. By open opposition, by innuendo and crimination, every effort has been made by the interests affected to disorganize the forces of therapeutic decency and to destroy the splendid work the Council is doing. Happily, however—and to the credit of the organized profession be it said—these efforts and this destructive criticism have failed, for the profession has decided that the work of the Council *is* worth while, that the advance made shall be maintained and that therapeutics shall not be allowed to lapse into its previous deplorable condition of utter subjection to the commercial spirit.

WILLIAM HENRY WELCH

The great dinner[1] in Baltimore April second, in honor of Dr. Welch, President-Elect of the American Medical Association, is unique among events of this kind because of the participation in it of so many representative leaders not only in medicine but also in the fields of general learning, of industry and commerce, and of politics. This outstanding feature of this remarkable event testifies better than almost anything else could to the general appreciation of the truly commanding position which Dr. Welch occupies and for many years has occupied in the medical and scientific activities of the country. How he reached such pre-eminence cannot be told fully at this time; a few imperfect and cursory touches only may be given of his remarkably useful career, the keynote of which is the unselfish and untiring devotion of a superb and finely trained intellect to the service of medicine. After his graduation in medicine (College of Physicians and Surgeons in New York, 1875), Dr. Welch turned his attention to pathology and for the next three years or so we find him at work in various German laboratories. Under the direction of that brilliant experimental pathologist Cohnheim, whose death at a comparatively early age seems such a great loss to science, he completed an important investigation on experimental pulmonary edema. He was present in Breslau when Koch, then unknown, came from Posen to show Cohnheim his work on anthrax and heard the latter's prophetic remark: "There is a great man of whom we shall hear much in the future!" A few years later, he took part in Koch's first course in bacteriology in Berlin. This must suffice to indicate the nature and extent of his earlier training.

He was professor of pathology in Bellevue Medical College in New York, when he was called to the newly founded Johns Hopkins University as professor of pathology and pathologist to the Johns Hopkins Hospital, being the first member of the faculty that was entrusted with the difficult task of establishing a complete medical school on the highest plane yet attempted in this country. The success of that attempt and its influence on our ideas of medical education in general are now matters of history. That the Johns Hopkins Medical School has been one of the leading medical schools of the world since its first inception, owing largely to the wise counsels, lofty ideals, and ability of Dr. Welch, its first dean, is not questioned by any one at all familiar with its development.

We may now consider briefly Dr. Welch in the threefold capacity of teacher, investigator, and adviser in affairs of medical and scientific nature. Dr. Welch is a great teacher. Always fully abreast with many lines of work by virtue of a faculty of easy acquisition, following closely the developments with keen and critical appreciation, endowed with an apparently phenomenal memory, he possesses an enviable power to impart knowledge with a facility that excludes all sense of its costing any effort whatever. Lucidity and ease of expression, close reasoning, the thoughts moving in orderly sequence, a judicial calmness and an all-pervading sanity—these are striking characteristics of his writing and speaking.

Primarily a pathological anatomist firmly rooted in cellular pathology, he has produced original work of the highest quality in pathologic anatomy, in experimental pathology, and in bacteriology, the details of which need not be given here. Many of his articles and contributions to text-books and systems are classical in their comprehensiveness and clearness; for example, the introduction to general pathology in Flint's work on practice, the article on thrombosis and embolism in Allbutt's system, the Huxley lecture on immunity, the papers on venous thrombosis in cardiac disease and on infections caused by the *B. aerogenes capsulatus* (discovered by Welch and Nuttall in 1892 and sometimes known as *B. welchii*).

Associated with profound scientific and scholarly attainments is the grace and charm of a personality that inspires affection and intellectual effort. Consequently a large amount of fine investigative work has been carried out by assistants and students working under the direction of the master. The pathologic laboratory of the Johns Hopkins Hospital very soon became the accepted center—the pathologic mecca—in the United States and Canada for investigation and training in pathology. Now former workers and assistants in that laboratory occupy a large number—too large to enumerate—of our most important pathologic posts, while many others have reached eminence in other branches of medical science as well as in practical medicine and surgery. Dr. Welch has had a larger part than any other person in training those who are now leading and about to take the lead in our medical teaching and investigation.

---

[1] Reported in the News Department in this issue.

Many-sided, of clear vision, and in close touch with every aspect of medical science, Dr. Welch is rendering most important service in the capacity of adviser not only to individuals but also to institutions and to local and national governmental bodies. It is said that his advice led to the creation of the Yellow-Fever Commission of the U. S. Army, which, with the lamented Reed at its head, accomplished the epochal discovery of the rôle of the mosquito in the spread of yellow fever. The needed presence of a medical man on the Isthmian Canal Commission is due largely to the same influence. Occasionally instances become known illustrating that suggestions from Dr. Welch have borne rich fruit through the work of others, notably the demonstration of the filterable character of the yellow-fever virus. An enumeration of the more important positions occupied by Dr. Welch at the present time will emphasize better than anything else the value placed on his advice and co-operation: He is president of the board of directors of the Rockefeller Institute for Medical Research, the director of which, Dr. Flexner, his former assistant, is doing such splendid work; member of the board of the Carnegie Institution and chairman of the executive committee; president (since 1898) of the Maryland Board of Health; member of the Charter Revision Committee of Baltimore, and, last but not least, President-Elect of the American Medical Association. And here we take leave for the present of our representative in a uniquely wise significance, while at the zenith of a career of unparalleled usefulness, universally respected, honored as few are honored, beloved by all who know him.

THE AUTOMOBILE AND THE PHYSICIAN

The automobile is a part of the higher standard of living toward which all are striving, and in many occupations and conditions is as indispensable as the other necessities of to-day which only yesterday ceased to be luxuries. It is no longer a plaything of the rich; it is an efficient aid in practical progress—in the every-day work of the world—just as is any other piece of labor-saving machinery. Like other epoch-making inventions, it is a social and industrial force, but its novelty, its convenience, and the pleasure and relaxation it affords have absorbed general attention largely to the exclusion of its wider significance and importance, which, after all, is a not infrequent occurrence in the case of innovations of far-reaching importance. A future by no means remote will no doubt show that its influence in many directions has been marked. It would be interesting to speculate a little along this line.

Civilization, it has often been said, depends much on transportation. There are, of course, limitations to the services which may be rendered by steam and electric railways and by water transportation; so that even with their fullest development certain areas will be left without those means of rapid communication. The automobile is supplying this hiatus in transportation facilities. It brings the remote districts into quick communication with the centers of business, in touch with the markets, with the cities, the centers of education and culture. Already it has had a wide-spread influence on the roads of the country, calling attention forcibly to the value of good roads for everybody, whether auto-users or not. It will make possible a vast extension of the rural mail service, aiding the dissemination of knowledge. It will make possible the centralization of country schools, which has been found desirable, and which is already attempted with the slower means of transportation. In rural communities it will make possible residence in towns or villages, with the many advantages which closer social communion offers, thus overcoming the chief objections to rural life, without interfering with the successful cultivation of the soil under the scientific methods now being so rapidly developed. On the other hand it will enable the dweller on the farm, by means of this time-eliminating device, to keep in close touch with his neighbors and friends, or with the neighboring city, town and village, with the social and cultural advantages they afford. With this concentration of the rural population in towns and cities, or even without it, it is evident that this means of locomotion will give every one freer access than ever before to all the privileges of hospitals. More hospitals will no doubt be built in the smaller places; and the manifest advantages to the sick and the well need be no more than suggested here.

To the physician perhaps more than to any other member of the community the automobile is indispensable. Business can wait, if need be, but the work of the physician requires prompt attention always. His duties call him hither and yon, frequently at time-consuming distances. The automobile offers him a mode of conveyance which is always ready and which enables him to cover much ground at the least expense of time. Naturally it wins his approval, as is evident from the articles in this issue. These contributions from many readers express various opinions about the automobile, the kind of car to choose and the way to care for it, but with few exceptions they are favorable to its use by the physician.

It is interesting to compare the contributions of this year with those of previous issues. Some problems are passing away and new ones have taken their place. The high-wheel car seems to be less used. The pneumatic-tire problem is still with us, no substitute which is entirely satisfactory having been found. The pneumatic tire, however, is being perfected, and when properly used is giving somewhat less trouble than before.

Automobiles as a class are now made more reliable than those of two or three years ago. They are more available for the man who must be his own chauffeur and mechanician. The time seems not far away when it may almost cease to be necessary for a man to have some little mechanical ability in order to be a successful automobilist. Apparently there are a number of cars on the market which will give eminent satisfaction to the physician. It is clear, however, that the automobile cannot be operated and maintained for little or nothing. A man who uses it considerably for pleasure is apt to feel the need of an increase in his income. On the other hand, the man who uses his automobile largely for his practice will surely add to his income. It is the almost universal testimony that it enables a man to cover more ground and to see more patients and still to have more time for study and pleasure.

A part of the space given to the subject in this issue is taken up with an analysis of the replies to questions which we published asking for various facts in the experience of our automobile readers. We take this occasion to thank our contributors for what they have written, and to express the desire that the automobile may continue to be a source of profit and recreation to them.

THE NAMES OF THE AUTOMOBILES

As has been the custom, the names of the machines referred to are not given in the automobile articles, but are designated by reference numbers. A folder containing these numbers and the corresponding names and also containing a list of names and addresses of automobile manufacturers will be sent to any one who requests it and encloses a self-addressed, stamped envelope. Automobile contributors and those who sent in answers to the questions we printed need not ask for the key as a copy will be sent to each of them.

THE TEMPTATION TO "SCORCH"

There is probably no profession or occupation that has received more benefit from the advent of the automobile than has the medical profession. The time saved in going about enables the practitioner to widen the area of his activities, to see more patients, and, above all, to have more leisure for study, for reviewing his case histories and for recreation. The recognition of these advantages constitutes a constant temptation to reap more benefit by hurrying while on the road, and the habit of hurrying tends to foster that enjoyment of speed for its own sake which, when unrestrictedly indulged, has been aptly termed the "speed mania." All but the most timid have felt the fascination of speed, and frequent indulgence in this pleasure soon leads to a dissatisfaction with milder paces that it is difficult to disregard. The physician's machine, with its red cross, is almost everywhere somewhat privileged in the matter of speed, and rightly so, as the comfort of some sick person is frequently at stake, and life itself may depend on the promptness with which the physician responds to a call. While physicians as a rule do not abuse this privilege, there are some who take advantage of the leniency of the police and of public opinion to maintain a speed which is a danger to themselves and to others. Of the innumerable automobile accidents that occur no small proportion is due to excessive speed and careless driving. In a matter which so directly concerns the public safety the physician surely should set an example and avoid even the appearance of putting in jeopardy the life and limb of passers-by. The sentiment within the profession should be strong enough to discourage the immoderation of the few who are reckless. Having taken heed of the beam in our own eye, we can turn with better grace to the mote in the eye of the lay scorcher. When an abuse endangers the public, the medical profession, above all others, must be beyond reproach, or be condemned out of its own standards and precepts.

SANITATION IN PANAMA

The annual report of the Department of Sanitation of the Isthmian Canal Commission for the year 1909, just issued, shows that the remarkable record already established by this department has been fully maintained. Colonel Gorgas' letter of transmittal shows that the death-rate for the past six years has been as follows: 1904, 13.26; 1905, 25.86; 1906, 41.73; 1907, 28.74; 1908, 13.01; 1909, 10.64. The marked decrease since 1906 is in spite of the large increase in the number of employes; in 1906 there were 26,547 and in 1909, 47,167. The total number of deaths in 1909 were only a very few more than the total number in 1905, at which time, the entire force only numbered 16,512. Still more remarkable is the death-rate from disease among white employes, which only amounted to 3.88 per thousand for the year. The death-rate from special diseases is also remarkably low. During the year, there were only 13 deaths from typhoid, a ratio of 0.27 per thousand, while the death-rate from typhoid in the state of Pennsylvania for the same period was 5.03 per thousand. Only 8 deaths from dysentery occurred, not one of which was among white employes. The death-rate from pneumonia was about the same as that in New York City, while the total number of deaths from malaria for the year amounted to only 52. If the cities of Panama and Colon and the country in the Canal Zone between them is included, the total death-rate for all inhabitants for the entire year is 18.19, or 31 deaths less per thousand than in 1905, a saving of over 4,000 lives. The most remarkable of all, however, is the fact that not a single case of yellow fever, bubonic plague, or smallpox has occurred on the Isthmus during the past year. The work of the Sanitary Department of the Isthmian Canal Commission continues to be an object lesson of what can be accomplished by careful, patient, scientific work in freeing tropical and pest-ridden regions from diseases and in saving the lives not only of Europeans and Americans but of the natives as well.

Medical News

ALABAMA

Conference of Charities and Corrections.—At the annual meeting of the Alabama Conference of Charities and Corrections, held in Birmingham, March 22, the following physicians were elected to office: Dr. Thomas D. Parke, Birmingham, president; Dr. John B. Stagg, Pratt City, member of committee on membership. Among the interesting topics discussed was the "Assimilation of the Immigrant," on which a paper was read by Dr. Haickel A. Elkourie, which was discussed by President Abercrombie of the University of Alabama.

ARIZONA

Personal.—Dr. Ralph L. Alexander, Tempe, has been appointed local surgeon to the Maricopa and Phoenix and Phoenix and Eastern railways.——Dr. Clarence Guenter has been appointed assistant chief surgeon of the Randolph Lines with office in Tucson.

State Association Meeting.—The nineteenth annual session of the Arizona Medical Association will be held in Phoenix, April 20 and 21, under the presidency of Dr. Robert N. Looney, Prescott. The oration in medicine will be given by Dr. J. Wilson Shiels, San Francisco; the oration in surgery by Dr. Wesley W. Beckett, Los Angeles, and the oration on state medicine by Dr. James A. Egan, secretary of the State Board of Health, Springfield, Ill.

CALIFORNIA

Health Interests to Merge.—Representatives of leading public health associations of the state will meet in Sacramento April 18, to discuss the project of merging the health interests in a general association, to be known as the "Affiliated Health Associations of California."

Rules Against Vaccination.—In the case of the State Board of Health against the city of Watsonville, in which the board of education refused to enforce the new vaccination law, Judge Lucas F. Smith in the superior court of Santa Cruz, is said to have decided that vaccination law is unconstitutional and that it is class legislation in that it provides for vaccination of public school children and not private school children.

Medical Society Sues.—The Medical Society of the State of California has brought suit, based on the violation of the copyright law, in the circuit court asking an injunction against the Kaplan Medical Publishing Company. The defendant company published the official register for the society for the three previous years, and in October and January is said to have included the register in its own digest published quarterly.

Personal.—Dr. Charles R. Blake has been appointed health officer of Point Richmond, vice Dr. Hawley N. Barney.——Major Paul A. Adams, Los Angeles, surgeon of the First Brigade, N. G. Cal., has resigned and has gone to Honolulu as First Lieutenant, Medical Reserve Corps, U. S. A. Dr. Charles W. Decker, Los Angeles, has succeeded Major Adams.——Drs. Elmer R. Pascoe, J. S. Derrick, Charles T. Palmer and Chester L. Magee have been appointed assistant health officers of Los Angeles.——Dr. William E. Carter has been appointed assistant police surgeon of Los Angeles, to succeed Dr. Charles W. Bonynge, who has resigned and will take charge of the State Board of Health laboratory, Berkeley.——Dr. Philip A. Bill, North Beach, San Francisco, was assaulted and robbed near his home, March 7.——Dr. William T. Lum, Alameda, has been appointed a member of the board of education.

ILLINOIS

Chicago

Rush College Alumni.—At the twentieth annual reunion and dinner of the class of 1890 of Rush Medical College, Drs. E. Fletcher Ingals and Arthur D. Bevan delivered addresses. Dr. T. F. Wilcox was elected president; Dr. Henry D. Anderson, second vice-president; Dr. Emanuel Friend, Chicago, secretary, and Dr. Thomas H. Culhane, Rockford, necrologist.

Personal.—Dr. E. Fletcher Ingals has been elected an honorary member of the Vienna Laryngologic Society and corresponding member of the Royal Society of Physicians, Budapest.——Dr. Howard T. Ricketts, assistant professor of pathology in the University of Chicago, has resigned to accept a professorship of pathology in the University of Pennsylvania.——Dr. Hugh A. Cuthbertson and sister and Dr. James T. Campbell and mother sailed from Boston, April 2, for Vienna via the Mediterranean.

Anti-Spitting Crusade.—The first concerted movement by Chicago organizations to enforce the anti-spitting ordinance was started March 31, at a meeting attended by representatives of the police and health departments, men's and women's clubs, social settlement, United Charities and the Chicago Tuberculosis Institute.——The Chicago City Railway Company has announced that it will have new posters placed in all its cars warning against spitting, and that transfers will have similar matter printed on their backs.

KENTUCKY

New Hospital.—The Children's Free Hospital, Louisville, has been completed and was formally dedicated April 1.

Personal.—Dr. Edward Davenport, Hampton, was operated on in Paducah, March 18, for appendicitis.——The office and equipment of Dr. William C. Wilkerson, Clintonville, was destroyed by fire, March 17.

A Graphic Object Lesson.—The Louisville *Courier-Journal*, in its issue of March 24, published a series of illustrations to show that the Louisville City Hospital is crowded and in bad need of repair, as an object lesson to create public sentiment in favor of the bond issue of $1,000,000 for a new hospital, to be voted on in November.

Society Meetings.—The Paducah Medical and Surgical Society met recently and reelected for the third time the following officers: Dr. John G. Brooks, president; Dr. Oliver R. Kidd, vice-president; and Dr. James T. Reddick, secretary-treasurer.——At the annual meeting of Hardin County Medical Society, held in Elizabethtown, March 10, an insurance society was organized, to be known as the Hardin County Insurance Society, and the following officers were elected: Dr. D. C. McClure, president; Dr. John M. English, Elizabethtown, vice-president; and Dr. Charles T. Riggs, Upton, secretary.

MARYLAND

Personal.—Dr. R. C. Wells has been elected health officer of Hamstead.——Dr. J. McPherson Scott has been elected mayor of Hagerstown.

Optometry Bill Passes.—The optometry bill, which was opposed by the Medical and Chirurgical Faculty of Maryland, passed the senate April 1. Thirteen counties were exempted from operation, but Baltimore City was not included.

Baltimore

The Welch Dinner.—The banquet to Dr. William H. Welch is reported in General News and is also commented on editorially.

Entertainment for Children's Hospital.—The proceeds of the performance of "The Belle of New York" by the Paint and Powder Club, March 28, amounted to $2,850. This will go to the Children's Country Hospital School, located in the suburbs of Baltimore, which has accommodation for 25 patients.

Alumni Meeting.—At the annual meeting of the General Alumni Association of the University of Maryland, held in Lancaster, Pa., Dr. Eugene F. Cordell spoke on "The Duty of the Alumnus," Dr. Henry W. Fishel, Harrisburg, Pa., was elected president, and that city was chosen as the meeting place for 1911.

Personal.—Dr. Henry Barton Jacobs has been elected governor and Dr. B. Bernard Browne, historian, of the Society of Colonial Wars.——Dr. William D. Booker, clinical professor of pediatrics in Johns Hopkins Medical School, has asked to be relieved of his duties and has been made emeritus professor.——Drs. Louis V. Hamman and Paul W. Clough sailed for Europe April 2.——Dr. Harvey W. Cushing of Johns Hopkins Medical School, has under consideration a call to Washington University, St. Louis.

MISSOURI

To Enlarge Medical School.—The plans of President Brookings for the enlargement of the Medical Department of Washington University have been given an impetus by the voluntary offer of Adolphus Busch to join other citizens of St. Louis and the state in a movement to provide St. Louis with a medical college similar to Johns Hopkins University, Baltimore.

Alumni Association Meets.—The Barnes University Alumni Association, at its annual meeting, March 25, elected the following officers: President, Dr. Walter U. Kennedy; vice-presidents, Drs. Orril L. Suggett and Genevieve S. Beckham; secretary, Dr. Charles A. Vosburgh, and treasurer, Dr. Elbert J. Lee, Jr., all of St. Louis. The association decided to give a banquet during the meeting of the American Medical Association.

Personal.—Dr. Henry E. Miller, St. Louis, has returned from abroad.——Dr. Newton McVey, Kansas City, has been appointed state bacteriologist.——Dr. Abra C. Pettijohn, Brookfield, has been elected superintendent of State Hospital for the Insane, No. 2, St. Joseph.——Dr. William R. Strickland has been appointed postmaster of Rockport.——Dr. C. A. Gould has been appointed assistant city pathologist of St. Louis.

NORTH CAROLINA

Charter Granted Sanitarium.—A charter has been issued to the Greensboro Sanitarium with capital stock of $100,000.

Hookworm Work.—Dr. John A. Ferrall, Kenansville, has been designated by the North Carolina State Board of Health as special assistant secretary for the study and prevention of hookworm disease, and has removed to Raleigh.——Dr. Charles W. Stiles, United States Public Health and Marine-Hospital Service, has taken up his residence in Raleigh, and will make the city his official headquarters for the work of the Rockefeller Hookworm Commission, in its special investigation in the southern states.

Personal.—Dr. Edward J. Wood, Wilmington, has been elected president of the Medical Society of the State of North Carolina to fill the unexpired term of the late Dr. James A. Burroughs, Asheville.——Dr. John A. Williams, Greensboro, announces his retirement from general practice April 1. He will give his entire attention to surgery and consultation work.——Dr. Lucius B. Morse has moved his sanatorium from Chimney Rock to Hendersonville. The new building will accommodate 30 patients.

NEW YORK

Tuberculosis Preventorium Incorporated.—The Tuberculosis Preventorium, founded by Nathan Straus, which has for its object the prevention of tuberculosis among children, has received a certificate of incorporation and may operate in the states of New York and New Jersey.

Appoints Delegates.—Among the delegates appointed to represent the state at the National Conference of Charities and Corrections which will convene at St. Louis, May 19 to 26, are Drs. Albert W. Ferris, New York City, Charles F. Howard, Buffalo, and Hortense V. Bruce, Hudson.

Study of Hysteria.—The State Lunacy Commission announces that a systematic study of hysteria will be begun in the various state hospitals under the jurisdiction of the commission. This work is the result of the methods and studies introduced by Dr. Adolph Meyer, retiring director of the Pathological Institute.

Open-Air School.—Rochester is making a new effort to safeguard the physical welfare of its school children, and has established an open-air school, the outcome of the day camp established by the Rochester Public Health Association, through the efforts of Mrs. Porter Farley and Dr. Montgomery E. Leary. The first sessions of the school were held at the day camp, and these were continued until the Christmas holidays. Children from the entire city are admitted after examination by Dr. Joseph Roby, physician in charge, and carfare is furnished these children by the association.

Tuberculosis Talkettes.—The Rochester Public Health Association has decided to publish a series of forty leaflets on the various phases of the tuberculosis problem, which will be distributed to every health association in the country. The first "talkette" will be on "Consumption; A Brief History of the Disease," by Dr. Montgomery E. Leary, supervising director of the Public Health Association. Other talkettes to follow at short tintervals are on "Consumption; What it is and Why;" "Inhaling the Germ;" "Systems that Resist the Germ;" "Exploded Theory of Heredity;" "Carelessness;" "Fly, First Assistant to Death;" "Destruction of Tuberculous Expectoration;" "Destruction of Expectoration with Acids;" "Safeguarding the Public;" and "Disinfecting the Sick Room."

New York City

Learning How to Fight Tuberculosis.—A committee of seven appointed by the City Council of Portland, Me., has been visiting this city in order to learn how New York is fighting tuberculosis. The Health Commissioner spent a day showing them the methods employed by the Health Department and the city hospitals.

Precaution for a Safer Fourth of July.—Fire Commissioner Waldo, pursuant to an order from Mayor Gaynor, has issued the following notice, which should prevent the large number of accidents and cases of tetanus that have occurred in past years: "Notice is hereby given to all concerned that the Fire Commissioner hereafter will not issue any permit for the retailing of fireworks, Chinese crackers, rockets, blue lights, Roman candles, colored pots, lance wheels and other works of brilliant colored fire."

Boiled Milk Recommended.—At the direction of Health Commissioner Lederle an exhaustive examination of New York's milk supply has been made which has disclosed the fact that several epidemics of typhoid fever are directly traceable to infected milk. One epidemic was traced to a milk handler who was a typhoid patient forty-six years ago and during all the intervening years has been a distributor of typhoid bacilli. The work has been carried on under the direction of Dr. Herman M. Biggs, and on the presentation of his report to the Board of Health the three members, Commissioner Lederle, Health Officer Doty and Police Commissioner Baker adopted a resolution recommending that milk used for drinking purposes should be either pasteurized or boiled. It was also stated that it seemed probable that a certain percentage of the cases of diphtheria and scarlet fever occurring in New York City result from milk infection.

PENNSYLVANIA

Philadelphia

Personal.—Dr. Alexander C. Abbott has been selected as delegate to the International Congress on Hygiene and Medicine which meets in Buenos Aires next month.——Dr. Charles H. Frazier, clinical professor of surgery at the University of Pennsylvania, was operated on for appendicitis, March 30.——Dr. Almer H. Tomlin, who was operated on for appendicitis at the German Hospital, March 30, is reported to be improving rapidly.——Dr. M. F. Shaughnessy sailed for Europe, March 30.

Insurance Company's Life-Saving Movement.—The Metropolitan Life Insurance Company has made arrangements with the Visiting Nurse Society of this city to carry on the company's scheme of visiting sick policyholders in their homes and giving them all possible aid to tide them over their illness. The movement is not philanthropic, but a purely business arrangement. The policy of the company is to cooperate with the attending physicians, and the nurses' business will be to carry out the doctor's orders, and prevent the disastrous consequence of ignorance and neglect in the sick room. The free nursing service will be extended to the rich, poor and middle classes, irrespective of the amount of insurance they carry and of creed, nationality and color. It includes not only attention during the day, but will provide a nurse at night if the patient is critically ill.

Old-Home Week at the University.—Old-Home Week of the Medical School of the University of Pennsylvania was inaugurated, March 28, with clinics and a luncheon at the University Hospital. In the evening several hundred physicians attended the smoker of the Philadelphia Alumni Society of the Medical Department. Vice Provost Edgar Smith gave an illustrated lecture on the progress of the university since its founding. Following the lecture an appeal was made by Dr. Swithin Chandler to start a fund to erect a monument to Dr. John Morgan, the first dean, over his grave in St. Peter's Church, Philadelphia. The following officers of the Philadelphia Alumni Association were elected: President, Dr. George C. Stout; honorary vice-president, Provost C. C. Harrison; vice-presidents, Drs. J. Gurney Taylor, Lewis H. Adler, Jr., and Howard A. Sutton; secretaries, Drs. B. Franklin Stahl and Herbert S. Wray; treasurer, Dr. Herbert B. Carpenter; executive committee, Drs. Luther C. Peter, Charles A. E. Codman, Clarence P. Franklin, Stephen E. Tracy and Charles J. Hoban. On March 29 the centenary of the foundation of the chair of obstetrics was commemorated with exercises at the College of Physicians. This included an address by Dr. Barton C. Hirst, on Richard Penrose and biographies of Professors Chapman and Jackson, to whom tablets were unveiled Wednesday, were read by Drs. S. Weir Mitchell and James Tyson. On Wednesday the bronze tablets of Chapman and Jackson were unveiled in the Medical Building by Dr. R. Tait McKenzie. Dean Allan J. Smith of the medical department delivered the address of acceptance.——The banquet of the medical alumni was held Wednesday evening at which nearly 300 were present. At the close of the banquet, Provost C. C. Harrison made an address, the chief interest of which was the announcement of faculty changes and new appointments. These were detailed in THE JOURNAL last week, page 1145. The following officers of the Society of the Alumni of the Medical Department were elected: President, Dr. Samuel S. Stryker, '66, Philadelphia; vice-president, Drs. James B. Walker, '72, Philadelphia; George A. Piersol, '77, Philadelphia; Charles W. Burr, '86, Philadelphia; George W. Guthrie, '76, Wilkesbarre; Edward Jackson, '78, Denver; William A. Edwards, '81, Los Angeles;

Thomas M. T. McKennon, '82, Pittsburg; historian, Dr. Roland G. Curtin, '66, Philadelphia, and secretary and treasurer, Dr. Edward A. Shumway, '94, Philadelphia.——The members of the class of 1890 of the medical department, who returned for "Home Week," celebrated the twentieth anniversary of their graduation at a banquet, March 31, at which 18 members of the class were present. The class of 1884 held an informal dinner the same evening over which Dr. George E. de Schweinitz presided.

OHIO

Greene Guest of Honor.—Three hundred members of the Montgomery County Medical Association tendered a banquet to Dr. Duff W. Greene, Dayton, March 4, to celebrate his homecoming after an extended tour of professional research in India.

Personal.—Dr. Daniel W. Reddin, North Baltimore, was operated on for appendicitis, March 21.——Dr. Edgar B. Foltz, Akron, sailed for Europe, April 2.——Dr. Jerry M. Hyde has been appointed health officer of Nelsonville.——Dr. Ezra Burnett, Delphos, was thrown from his buggy in a runaway accident, March 9, and sustained painful injuries.——Dr. Frank W. Rodgers, Findlay, is reported to be seriously ill with paralysis.——Dr. Mark Millikin, Hamilton, has been appointed local surgeon for the Pan Handle System.——Dr. William D. Cunningham has been appointed health officer of Girard.

RHODE ISLAND

Personal.—Dr. Charles F. Peckham, Providence, has been elected surgeon-general of the Rhode Island National Guard, vice Dr. George H. Kenyon, Providence, resigned.——Dr. Frederick T. Rogers, Providence, was operated on for appendicitis at Parade St. Sanitarium, February 17.

Society Election.—Providence Medical Society, at its annual meeting March 7, elected the following officers: President, Dr. Jacob C. Rutherford; vice-president, Dr. Franklin P. Capron; secretary, Dr. Frank M. Adams; treasurer, Dr. Winthrop A. Risk: councilor, Dr. Joseph H. Akers, and delegates to the state medical society, Drs. Herman C. Pitts, George S. Mathews, Frederick G. Phillips, Henry W. Burnett, Charles F. Deacon, George T. Spicer, Carl R. Doten, George H. Crooker, Clarence H. Gardner and Franklin P. Capron.

SOUTH CAROLINA

Health Officers Elected.—At the annual meeting of the Charleston Board of Health, Dr. John L. Dawson was reelected vice-chairman, and Dr. J. Mercier Green, secretary.——Dr. Edwin P. Derrick has been elected a member of the board of health of Lexington.——At the reorganization of the board of health of Anderson, Dr. Joseph O. Wilhite was elected chairman and Dr. J. Bennett Townsend, secretary.

TENNESSEE

Personal.—Dr. Edwin B. Anderson has been elected chief of the summer medical staff of Erlanger Hospital, Chattanooga, vice Dr. Henry Berlin, and Dr. J. Jefferson Gee has been elected secretary of the staff.——Dr. George E. Hatcher has been appointed assistant superintendent of the Central Hospital for the Insane, Nashville.

Hospital News.—Dr. George W. Hubbard, dean of Meharry Medical College, Nashville, announces that the work on the new George W. Hubbard Hospital will soon be commenced. The building will have cost $50,000 when completed.——At a meeting of the Chattanooga Tuberculosis Sanatorium Association, March 9, an eighty-acre tract of land near Tyners, donated by the City Water Company, was accepted, and a committee was appointed to raise funds for improvement of the site and the erection of buildings thereon.

TEXAS

District Society to Meet.—The Northwest Texas Medical Association will hold its annual meeting in Wichita Falls, April 12 and 13, under the presidency of Dr. Wade H. Walker, Wichita Falls.

Medical Society Organized.—At a meeting of the local physicians, March 24, the Nacogdoches Medical Society was organized, with Dr. Joel H. Barham, president; Dr. John H. Reagan, vice-president, and Dr. Robert P. Lockey, secretary-treasurer.

Quarantine Station Completed.—The state health officer, Dr. William M. Brumby, reports that the Galveston Quarantine Station is now completed. It now includes a modern hospital, wharves and slips, and is now prepared to cope with any emergency that might arise.

Personal.—Dr. Morris Boerner has resigned as a member of the staff of assistant physicians of the State Lunatic Asylum, Austin.——Dr. H. Powell Luckett has resigned as city physician of Bastrop.——Dr. Thomas J. Milner, Greenville, has been reelected health officer of Hunt county.——Drs. Thomas W. Moore and Otto Ehlinger, LaGrange, were painfully injured in a runaway accident, February 12.——Dr. Paul Renger, health officer of Hallettsville, was operated on recently in Cuero for appendicitis.——Dr. L. C. Logue, Columbus, has been appointed a member of the staff of assistant physicians of the State Lunatic Asylum, Austin.

VIRGINIA

Railway Surgeons Coming.—The Association of Southern Railway Surgeons will assemble in Richmond May 24, for its fifteenth annual meeting, under the presidency of Dr. Charles H. Starkel, Belleville, Ill.

Dentists Must Have Medical Education.—Last week the state legislature passed a law requiring that all dentists entering the state to practice after Jan. 1, 1914, shall have a medical education.

Legislative Appropriation.—The House of Delegates has appropriated $40,000 for the State Board of Health and $40,000 for buildings and improvements at the Catawba Sanatorium for Tuberculosis for the first year; for the second year, $20,000 is appropriated for the board and $27,000 for maintenance of the sanatorium.

Indictment Quashed.—An indictment recently returned by the Norfolk grand jury against Drs. J. J. McKanna, Jr., and Charles Lincoln, charged with practicing medicine without a license, was quashed in the corporation court, February 14, on the ground that the charges were not specific.——Dr. McKanna has, it is said, agreed to leave the state.

Personal.—Dr. Guy Hinsdale, Hot Springs, has returned from a visit to Europe.——Dr. Powhatan S. Schenck has been reappointed state quarantine officer at Norfolk.——Dr. Carlisle L. Nottingham, Cape Charles, has been appointed a member of the board of health of Northampton county, and surgeon-in-chief of the New York, Philadelphia and Norfolk Railroad.——Dr. Garland P. Moore and family, Cape Charles, have started for Japan.——Dr. Joseph N. Barney, Jr., Fredericksburg, has been appointed a member of the State Medical Board for the first congressional district.

WISCONSIN

New Tuberculosis Dispensary.—A free dispensary for tuberculosis was opened March 15, by the Society for the Care of the Sick, in Trinity Hospital Building, Ninth and Wells street, Milwaukee.

Sanatorium for Racine.—The city council has authorized the Racine Branch of the Wisconsin Antituberculosis Association to build and equip two cottages for the care of advanced cases of tuberculosis on the grounds of the present isolation hospital.

Personal.—Dr. Arnold H. Drexel, Milwaukee, has started for Vienna.——Dr. Hasse A. Meilike, Clintonville, has been reappointed a member of the State Board of Health and Vital Statistics.——Dr. William J. Allen, Beloit, has been appointed assistant health officer.——Dr. George N. Hidershide, Arcadia, who is under treatment at Winona Hospital, is reported as progressing favorably toward recovery.——Dr. Charles D. Packard, Rhinelander, who has been seriously ill with inflammatory rheumatism, is convalescent.——Dr. J. A. Drury, Peppin, has started for Europe.

GENERAL NEWS AND COMMENT

Dinner to Surgeon-General of Navy.—Surgeon-General Charles F. Stokes, U. S. Navy, was the guest of honor on March 29, at a dinner at the University Club, Philadelphia, tendered by Dr. Corbin J. Decker, U. S. Navy, at which a number of representative physicans were guests.

Canal Zone Physicians Meet.—The fourth annual meeting of the Canal Zone Medical Association was held at the Ancon Hospital, March 9. Dr. James C. Perry, Ancon, was elected president; Dr. Lloyd Noland, Cristobal, vice-president; and Dr. John W. Ross, Jr., Ancon, secretary-treasurer.

Transactions of International Congress Ready.—The general secretary of the Sixteenth International Medical Congress (Budapest) writes that the general transactions will be distributed to the members of the congress during April. According to the congress regulations, each member is to receive a copy of the general report as well as that of the section in which he was inscribed. They are to be accompanied by a work on "Protection of Child-Life in Hungary," presented to each participant in the congress by the Hungarian minister of the interior.

THE WELCH DINNER

Grand and Impressive Banquet Given to Prof. William H. Welch in Baltimore

The dinner to Prof. William H. Welch, held in honor of his election as President of the American Medical Association, at the Belvidere Hotel, Baltimore, April 2, was the most remarkable banquet ever held in Baltimore. It was attended by about four hundred and fifty men and women, and no one left until it was all over, at about 1 o'clock in the morning. There were many distinguished guests present, some coming from a considerable distance. Letters and telegrams were read from many others, including some warm friends in England and Germany.

The designated reason for the gathering was to congratulate Dr. Welch on his being President-Elect of the American Medical Association, but the occasion provided a delightful opportunity to Dr. Welch's many friends and admirers of expressing their love and esteem, and honoring him for his attainments as a scientist and a citizen.

Dr. Welch passed to the dining-room through a double line of his applauding friends, and the ovation which he received was a remarkable one, such as is rarely given to a private citizen. The dinner itself was most elaborate and gave abundant evidence of the extraordinary pains which had been taken over every detail. The beautifully decorated hall was adorned with spring flowers, each table in a different manner, and an orchestra provided music.

Dr. William S. Thayer was Toastmaster and he presided in a most happy manner, introducing each speaker with most appropriate words. We give below his introductory speech in full. The addresses were by Dr. S. Weir Mitchell who also read a poem which is printed below and which was received with great delight, Dr. William T. Councilman of Harvard University, Dr. J. A. Witherspoon of Nashville, Tenn., Dr. S. Alexander of New York, Dr. Henry Barton Jacobs, Maj.-Gen. Leonard Wood, and Dr. Abraham Jacobi.

Dr. Jacobi spoke in characteristic vein and we are fortunate in being able to present his remarks in full below. Professor Councilman was decidedly facetious, declaring that "no man should receive credit for what he is," and assumed for himself and his associates the responsibility for having made Dr. Welch the great man he is. His remarks were most interesting and decidedly amusing. He paid a high tribute to Professor Welch, declaring that "no man has ever heard him say evil of his fellows." He declared Dr. Welch to be "incorruptible," "unsalable," and a man whom his associates had learned to love.

Dr. Witherspoon spoke in his usual eloquent vein and named Dr. Welch the "father of scientific progressive medicine" and "the smartest man in the world."

Dr. Henry Barton Jacobs was announced as the man who proposed the dinner and was applauded with the hearty appreciation of the assemblage for his part in such a successful and important function. He stated that the medallion which was such a prominent feature of the occasion was suggested as the most fitting memorial to Dr. Welch by Dr. Rupert Norton of Johns Hopkins Hospital. All the lights were turned off except one and that one shone brightly on the medallion amid rousing cheers. The medallion is of gold and contains the words: "From His Friends." Large bronze copies have been made for presentation to the Johns Hopkins Hospital and to the Medical and Chirurgical Faculty of Maryland.

We are printing below a number of the speeches and it is a matter of regret that we cannot give in full the others, which were not delivered from manuscript. Keyed up to the high pitch of enthusiasm which the occasion demanded, every speech was a gem and combined to make the occasion one never to be forgotten by those so fortunate as to be present.

INTRODUCTORY ADDRESS BY THE TOASTMASTER, DR. THAYER

Colleagues and Friends:—At the outset, in the name of Maryland and Baltimore, let me greet you who have come from distant parts to join in doing honor to the friend to whom every one of us owes a personal debt of gratitude and affection. And then for us all, and for the many others who cannot be here, let me tell him what a happy moment this is for us.

Last June, as one of the friends who is not with us to-night has said, the American Medical Association elected its foremost member to the presidency. But 'twas not without difficulty, for his modesty had led him to hide for some time behind the armour of protecting technicalities. And it may as well be confessed that his presence here to-night was obtained only by strategy.

When, last fall, through the generous initiative of Ellis and Jacobs, there was called together a small group of Welch's friends and students who felt that they must have some opportunity to express that which filled their hearts, it fell to me to tell Dr. Welch our plans. Our modest suggestion was met by a categorical refusal. The invitation was finally accepted only on condition that the demonstration should be essentially a "home affair," and that the gathering should be as small as possible.

Dr. Welch, we have kept our word. This is the smallest gathering which could begin to express what we would say to you.

And now that we have our friend prepared, as it were, on the table, the orthodox procedure would be to enter on a minute and critical and objective dissection—to lay bare coldly his accumulated treasure. But alas, one must confess the impossibility of objectivity in such a case. And so, to use the formula of the wise man who has insisted so amusingly on the necessary subjectivity of all utterances, I shall now proceed to say a few words about myself, *apropos* of Dr. Welch!

I well remember the first time that I ever heard Welch's name; it was nearly twenty-three years ago. An honored instructor had advised me to buy a certain book on the practice of medicine, because, in addition to the many excellencies of previous editions, this last had been revised, and in many parts largely rewritten by a certain Dr. Welch, whom he regarded as the ablest physician in the country. Three years later, as I was on my way to take up my work in Baltimore, another instructor told me that he felt that the greatest privilege of life at the Johns Hopkins Hospital would be the proximity to Dr. Welch. He well remembered an involved discussion at a medical meeting at the end of which a young man of modest appearance arose and in a few, wise, simple, direct words cleared up the whole matter. He had been immensely impressed and had since regarded him as one of the most remarkable and ablest men in this country. How well to-day, do we all realize the justice of this observation.

At this time, twenty years ago, his influence which had been felt so deeply in New York, had already been quietly exercised in the selection of the original staff of the Johns Hopkins Hospital. Already, for five years, he had been at work in the laboratory, surrounded by a group of students whose names are all well known to-day. From that little laboratory, cramped and crowded, even when I first knew it twenty years ago, what an inspiration has gone forth! Although the contributions which have appeared under Welch's name have been relatively few, his influence has been felt in almost every great work which has been done in the last twenty years by American students.

In the old laboratory by his side in the early years worked Sternberg and Councilman and Booker and Halsted and Sewall and Nuttall and Mall and Abbott and Williams and Howard and Flexner and Hewetson and Barker and Reed and Cullen and Wright, and many others. And what suggestion and encouragement did we all receive from the delightful talks when the "Father," as we lovingly called him, passed from desk to desk, and from his words at the meetings of the little medical society in the hospital library. But that inspiration was for no small group of men. One by one these students have carried abroad his spirit and his teachings until there is scarcely a laboratory in this country that does not contain men who owe their success to that which Welch has given them.

How rich already are the fruits of his work!

It is to you, Dr. Welch, that Councilman owes the inspiration that has guided his useful and eminent career.

It was your teachings that led to the able work of Mall and indirectly to the establishment of his department of which we are so justly proud.

It was your student, McCallum, whose contributions to our knowledge of malaria have been referred to, by one of the most eminent students in this field, as the most brilliant since the discovery of the parasite.

Reed, Lazear and Carroll were all your pupils, and 'twas with you and your old student and co-worker, Sternberg, that Reed discussed and planned the greatest achievement of American medicine—the discovery of the transmission of yellow fever.

It is your student, assistant and colleague, Flexner, whose absence to-night we so deeply regret, who presides over that great institution in New York, which the world owes to the generosity of Mr. Rockefeller. What a contrast, Dr. Welch, between that magnificent institution and your little laboratory—its legitimate mother. But, then, although this little lady is sadly in need of a new dress to-day, who knows what ova of promise she may still contain!

It is your student, Flexner, whose discovery of a protective serum against cerebrospinal meningitis is saving so many precious lives to-day.

It is to your wisdom and initiative more than to any other influence that are due any successes of the medical world started under your guidance.

These may be some of the notable results of your teachings and your influence, but they represent a small part of that which we owe you. The wide extent of your learning, and the kindly interest which you have taken in every one have brought it about that you have become the fountain to which all repair for counsel and advice. But such wisdom, such charity and kindness, such powers of judgment could not, of course, long remain the property of your students and associates alone. In matters medical you have become the general adviser of all. From one end of the country to the other no new departure is taken, no new laboratory is opened, no new chair is filled without your wise advice. How much the American Medical Association owes to your sage counsel as a member of the Board of Trustees no one will ever know.

As chairman of the Board of Health you have directly and indirectly brought more credit to the State of Maryland than almost any other living citizen.

In the oft-renewed contest with the forces of ignorance and fanaticism, allied too often, alas—unwittingly, let us hope—with influences purely sordid and vicious, you have been the fearless and masterly leader of the army of truth and light.

Not only in matters medical, but also in affairs of city and state do we seek your assistance, and one of your associates on the Charter Commission has recently testified to your growing "insight into the morbid activity of *Bacillus municipalis.*"

Among the various other ways in which your helpful influence has been felt, there is one on which special comment should be made. You have set us all a brilliant and beneficent example as the master of the art of exposition. This talent depends not only on your clearness of thought, but on a rare power of expression—a power which amounts almost to genius. No one can express a thought so simply and clearly as you.

The chief art of the true master of language lies in his simplicity.

Maeterlinck says somewhere: "The poet adds to every-day existence a something—I know not what—which is the secret of poets, and straightway it stands forth in its prodigious grandeur, in its submission to powers unknown, in its infinite relations and in its solemn misery. A chemist lets fall several mysterious drops into a vase which seems to contain only clear water, and all at once 'tis filled with a world of crystals which reveal to us that which was held in suspense in the vase where our imperfect eyes had seen nothing. So, in Philoctetus, the meager psychology of the three main characters forms but the walls of the vase which holds the clear water of every-day existence into which the poet is to let fall the revealing drops of his genius."

The beautiful symbol of the chemist and the poet has been brought to my mind more than once in listening to your words or reading your sentences. How often have the "revealing drops" of your genius brought out the crystalline kernel from involved discussion or ill-comprehended observation.

But, after all, your greatest work lies in the personal example which you have set to the hundreds of students who have passed under your care. You have taught us a religion of earnestness and simplicity and directness—a religion of charity and of self-restraint, a religion of work, not of words. You have helped us to love truth for truth's sake, and above all, you have spread far and wide that enthusiasm without which all effort is vain.

We honor you for your achievements! We respect you for your learning! We love you for yourself! And one and all, we greet you here to-night, lovingly, gratefully and happily, as master, teacher and friend.

ADDRESS BY S. WEIR MITCHELL

Mr. Chairman, Gentlemen, and You, my Friend, the Sacrificial Victim of the After-Dinner Hour: Travel in strange lands is the more pleasant for knowledge of the language spoken, and it was the fact of my lack of tongues which made me doubt how fit I was to appear on this pleasant occasion, where, as I learned somewhat appalled, everybody was expected to talk *Welch.* To stumble bewildered an intellectual tenderfoot in the learned land of Johns Hopkins might certainly give any man pause, but in the court of wisdom there must be of necessity a fool, and so I accept the position of the provider of sentimental folly and make my little venture.

'Tis said that hovering near your infant couch
The fairy forms of Art and Science flew
In generous counsel o'er the golden gifts
They bade a joyous future pledge to you.

And if, they said, your life shall fail to give
What Bacon called the "hostages to fate,"
Unnumbered friends shall challenge love with love,
And ever through thy happy hours elate.

Fair Nature, coyest of all maids that hold
Reluctant mysteries from their lovers dear,
Shall on victorious quests divinely smile
And tell her secrets to thy listening ear.

Not yours shall be, companioned by the stars,
To soar through space on thought's ambitious wings
To worlds unseen; nay, yours shall be to roam
That wondrous other realm of little things.

There, half unread, the ever less and less
Lost in the lessening less, eludes our sight
In space as sunless and more dark with fate
Than are the baleful planets of the night.

There shall you stand upon the twilight verge,
Where fades the sight of each material thing,
And baffled wonder, what an hundred years
To other eyes than ours may haply bring.

A lilliputian world to thee we give,
Where deadly swarm the grim bacterial blights,
With amboceptors strange malignant priests
For demon marriage with satanic rites.

Here stegomyia and anopheles
Are huge behemoths of this lesser sphere
Where gay spirilla wriggle lively tails
And vexed erythrocytes grow pale with fear.

"Be these your friends," the flitting fairies cried,
"But who is this that leads a pirate crew?
"Bacterium chronos! Get you gone from hence,
"Or hungry leucocytes we'll set on you!"

A truce to folly. Long ago for you
Has rung the fatal hour of Osler's jest:
Still young, the merry smile, the glowing mind,
No least sad failure ever yet confessed.

Life's summer overflow reserves for you
The golden days of lingering life's September,
October loitering waits for you, my friend,
And summer-haunted glories of November.

Perhaps Johns Hopkins has some secret charm
That lets professors very neatly swindle
The robber time and feel enfeebling days
Toward youthful vigor quite reversely dwindle!

Alas, a most appalling doom awaits!—
A pediatric clinic at the end—
Pertussis, measles, teeth to cut, and then
The bottle—but which bottle? Ah! my friend,

We'll ask of Kelly, he will surely know
When comes at last your latest, earliest year,
With all of physiology at fault
How shall you ever gently disappear?

Far be the day for you. One grief I own,
What science won my art has something cost
Since the clear mind and ever-ready smile
Were to the bedside visit sadly lost.

Ave et vale! O, magister, take
Greeting and blessing from our greatest soul!
The rippling sweetness of his echoing verse
I seem to hear from that far century roll.

Too poor my rhyme to fitly entertain
The stately splendor of the Latin line;
Ah! happy he to whom this greeting went—
Thy spirit—kinsman, Harvey, makes it thine:

Vir doctissime!
Humanissime!
Mihi Carissime!
Vale mi' Amantissime!
Tuus ex anima.

THE ADDRESS OF DR. JACOBI

Dr. Abraham Jacobi spoke as follows:

There are some inquisitive people in New York. One asked me what business I had in Baltimore. New York was good enough for such as I. "Business?" The dinner. "The dinner! What dinner?" The Welch *dinner*. "*For* what reason is there a Welch dinner just now?" What reason? William H. Welch. "I mean what occasion?" The occasion is William H. Welch. When I asked him the names of two among the greatest luxuries, I received no answer. Now, in my opinion, they are, firstly, to dine with a great man, particularly when a lot of others, such as you, are thrown in; and, secondly, to speak of him as he deserves—preferably in his absence. But *nobody* wants him absent just now. But, after all, why can't a fellow hear the fine things said about a fellow before the fellow is dead? I shall let him down easy perhaps by talking of myself a little.

I knew Dr. Welch thirty-five years ago; we worked together in Bellevue Hospital. Remember, I speak of him as he was then. I appreciated his pathology and clinical medicine; but he was full of all sorts of knowledge. He is modest—cannot help it—was made that way; never obtrusive, but he would teach. Because he had knowledge, he was modest and gentle; gentle even to me, though I was only his superior; and, what is better, *gentle to the sick*. I then felt certain that he would be a great physician or practitioner, whose make-up always requires, though it does not always furnish, head and heart. Then again I thought after a while I had been mistaken. He disappeared, went to foreign countries. Virchow and Cohnheim were still teaching us pathology—they do still, for that matter.

He returned more learned, but also more cosmopolitan; more of a medical man, but still more of a man.

Thirty years ago I delivered, before a foreign-born society in a foreign language, an address on what had just been founded as Johns Hopkins University. There was the first promise of a real university, with an actual university spirit, broad, wide horizon, warm, fertile and fertilizing, spiritual and moral. For that is the quintessence of the ideal of a university; understood or not, that was ever the ideal of a university; not as a modern teacher of the east proclaimed only last year, in a lecture room of the far west—a place where all sorts of specialties are taught. At that distant time I could say that so far as I, though only a practitioner but an adorer of the university idea and ideal, could see, the accession of William H. Welch would prove a solid foundation of a brilliant future for Johns Hopkins and an example for the future of American institutions. There are those whom our father Homer had in view when he said that not to all will the immortals appear. What he meant, and what he knew, was that they appear to some. Here is one of them. You know what he has been to Johns Hopkins, to its spirit, to its medicine, to all medicine, from the very beginning of his participation in Johns Hopkins labors. From the very beginning he was positive, but wise, learned but never pedantic, strong but prudent, keen and warm; the owner of many properties belonging to the young and strong, and to the old and wise. There are those qualities of the heart and brain which are attributed to advanced years only. But this man had and has his peculiarities. Indeed he does not believe, nor do I for that matter, that wisdom and ripeness must wait for the progressive stages of sclerotic arteries or overphosphated bones or a curved spine—at least he did not wait.

Some Welch Rabbits.—As one of the pleasing features of the dinner to Dr. Welch, the above cartoon was distributed. The artist was Prof. Max Brodel of Baltimore, whose artistic work in the portrayal of anatomic specimens and surgical procedures has frequently appeared in The Journal. He has very happily represented Dr. Welch as still the guiding spirit for these famous workers. For the benefit of our readers we name the positions of the men referred to:

Dr. J. Whitridge Williams, Professor of Obstetrics at Johns Hopkins Medical School.
Dr. Lewellys F. Barker, Professor of Medicine at Johns Hopkins Medical School.
Prof. George H. F. Nuttall, University of Cambridge, England.
Dr. William T. Howard, Jr., Professor of Pathology at Western Reserve University.
Dr. William S. Thayer, Professor of Medicine at Johns Hopkins Medical School and toastmaster of the evening.
Dr. Simon Flexner, Director of the Rockefeller Institute, New York.
Dr. William T. Councilman, Professor of Pathology at Harvard University Medical School.
Dr. Eugene L. Opie, Associate at Rockefeller Institute.
Dr. Franklin P. Mall, Professor of Anatomy at Johns Hopkins Medical School.
Dr. William G. MacCallum, Professor of Pathology at Columbia University.
Dr. Alexander C. Abbott, Professor of Hygiene at University of Pennsylvania.
Dr. George Blumer, Professor of Medicine at Yale UniversityMedical School.
Dr. Joseph C. Bloodgood, Associate Professor of Surgery at Johns Hopkins Medical School.
Dr. Thomas S. Cullen, Associate Professor of Gynecology at Johns Hopkins Medical School.

He never was a medical man only; a small part of medicine may *nowadays fill* the measure of many an alleged big man. Things were different one or two centuries ago. Then it was easy enough for a vast mind, endowed with sedentary habits and gluteal muscles, to carry a gold-headed cane, practice *medicine* according to the latest system and edit Greek or Latin incurables. A portentous doctor could be an erudite philologist and prove it. Nearer our times, Rush could sign our *independence*, *and* was, all by himself, an *army* surgeon, a busy practitioner, a prolific author and run mad over Brown. Cordell tells us that in the winter of 1789-90, George Burhanan taught in Baltimore the diseases of women and children and Brownianism: Wiesenthal anatomy, physiology, pathology, surgery, and the gravid uterus. They do not do that in Johns Hopkins any more. Their sins, if any, lie in different directions. But, cheer up, gentlemen, worse is *to* come. Holmes and Mitchell run off with Apollo to *Parnassus* and flirt, aye more than *merely* flirt, while we stand by applauding with a harem full of females, but they were nurses.

And Welch? Those who know him best, know what he has done for medicine. Medicine as a service, medicine as a part of biology and *vice versa*, and that he has worked assiduously—for life is but a song, and is wondrous long—effectually and accurately. But his accuracy was never a pharisaical fetish and no man ever lived who relied less extensively than he on the superstitious beatitude created by the actual or alleged single observation made by bending over a system of lenses only. What I always saw in him was of a different nature altogether.

When I was a boy Homer taught me that Podalirius and Machaon, the physicians of the besieging army were the most revered men, for a "healing man was to be esteemed as highly as a host of others;" by Xenophon that Socrates expected the welfare of the community to be safeguarded by doctors; later, by Descartes and Kant, that the refinement and culture of mankind must come from the teachings and practice of medicine; by our father Hippocrates, that where there is a love of medicine there is love of mankind. So I understand and applaud Welch. He is a great doctor, but a greater man. Medicine never was to him identical with one of the branches, or with the results of one or more surgical observations or revelations; not even the protection, valuable though it be, of an individual life. To him medicine has been the sum total of the physiologic knowledge of man and of the creation, and their history of the means of curing an individual accident; it is true, but more of preventing individual disease and morbidity and mortality, and those of the commonwealth, of guarding mankind against human waste by the prolongation of life, of making life in all ages, sexes, colors and stations bearable and enjoyable. That in view, he became a master in and presided over the Board of Health of Maryland; for that reason and for his universal fame whoever in these United States wants aid or counsel or direction, applies to Welch. That in view, he has created or caused to create a new charter for the administration of this big and warm-hearted city—he the learned pathologist, the great physician, the ripe statesman, the good citizen, *facillime princeps*, the dear good man.

THE RESPONSE OF DR. WELCH

When Dr. Welch rose to reply to these hearty expressions, he received another ovation and his manner showed how deeply he was touched by the events of the evening.

After expressing his thanks and grateful appreciation for the honor bestowed by the large gathering of physicians and friends, for the medallion portrait and the tributes of the various speakers, Dr. Welch said, in part: "While I am only too conscious that in the speeches and messages to-night the value of such service as I have been able to render to American medicine has been overestimated, it is true that I have had large opportunities for such service. These opportunities I owe to the profession, and it is of my debt to the profession that I wish especially to speak on this occasion. Every man owes a duty to his profession, and I should have been ungrateful indeed and recreant to a high trust if I had not endeavored to repay within my abilities the confidence reposed in me.

"The presence of Dr. Delafield at my right hand recalls my teachers and the large debt of gratitude which I owe to them. Whatever the defects of medical education in those days such teachers as these inspired their pupils with zeal and enthusiasm and high ideals. To Dr. Delafield I owe my first introduction to pathologic anatomy and his summer course with practical demonstrations awakened a lively interest, which became a genuine enthusiasm during my internship at Bellevue Hospital, where I was so fortunate as to come also under the inspiration of Dr. Janeway. In the wards of Bellevue Hospital I learned from Dr. Jacobi something of the thoroughness and spirit of German science."

Dr. Welch also spoke of his debt to his teachers in Germany and of the close ties formed with the profession in New York during his six years of connection with the Bellevue Hospital Medical College, where he said his chief delight was then, as it has continued to be, the teaching of students in the laboratory.

Grateful acknowledgement was made of the cordial reception by the profession in Baltimore and of his debt to the Johns Hopkins University and Hospital, where opportunities, previously unequaled in this country, were offered for the advancement of medical education. He expressed his good fortune in his associates and assistants, such men as Councilman, Abbott, Flexner, Barker and MacCallum, and the share of his colleagues in developing the medical school. It had been a privilege to participate in civic life, and to assist in the public health work of Maryland. While he regretted the dissipation of energy in undertaking so much outside work, it had been a great satisfaction to take part in the organization and development of the Rockefeller Institute for Medical Research. He said: "I have been highly honored by election to the presidency of the American Medical Association, the representative organization of the entire profession of this country. During the past decade the results accomplished by this association in the organization of the profession for higher standards in varied fields of medical activity have been perhaps the most significant event in American medicine. The Association should receive the loyalty and active support and cooperation of all physicians who have at heart the best interests of the profession and the advancement of American medicine."

After speaking of the educational and scientific progress of medicine during the past quarter of a century, and of the work of the physician in the future, particularly in preventive medicine, Dr. Welch, in closing, said:

"The attractions of a career in life lie in the opportunities it offers, in the congenial character of the work involved and the rewards to be gained. The profession of medicine is unsurpassed in its opportunities for service to one's fellow men. The manifold fields of activity now opened to the medical man appeal to the most varied personal inclinations and aptitudes, be these practical or scientific. The rewards of success, even of the highest success, are not in money. They are the intellectual pleasure which the physician finds in his work, the consciousness of service in the relief of suffering and the cure and prevention of disease, or it may be that highest satisfaction, some contribution to the advancement of useful knowledge, knowledge perhaps directly applicable to the healing of the nations.

"A reward to be dearly prized, but which has been conspicuously lacking for some of the great geniuses of our profession, is the expression of the esteem and good will of one's contemporaries of the profession and of the community. This highly prized reward has come to me to-night through your kindness and recognition, over-generous though they be, in overflowing measure, and in a form inspiring and never to be forgotten by me, which has touched my heart with profound gratitude, and which, I trust, will animate me with stronger desire to show, if I may, some return by increased devotion to high ideals of efficiency and service in such work as may remain for me to do."

In conclusion, the band played "Auld Lang Syne," in which all joined, standing, and the way it was sung showed that auld acquaintance could not be forgot.

BERLIN LETTER

(*From Our Regular Correspondent*)

Berlin, March 16, 1910.

Bill for the Regulation of Social Insurance

The new bill for regulation of compulsory insurance which is to reform the social legislation of Germany and which has been awaited with great interest by the German medical profession has now appeared. As I mentioned in a previous letter, the provisions of the bill first proposed, which provided for regulating the relations between the Krankenkassen and their medical officers, designed to hinder the constant strife between these two parties, met with energetic opposition on the part of medical men. Especially after the unanimous declaration of the Lübeck session of the medical association that the German physicians would not cooperate in carrying out the social legislation unless various demands were met in the new law, it was to be hoped that the government would accede to the wishes of the medical profession, but the upper limit of an income of $500 for the insured has not been generally established; exceptions are made in the case of laborers, helpers, companions, apprentices and servants. These are included in the provision for free Krankenkassen treatment even if their annual wage exceeds the sum of 2,000 marks. Further, as provided in the first bill no physician may be prosecuted on account of infringement of medical ethics or of his duty to the medical profession, if he has made a contract with the Krankenkassen under conditions which conform to the statutes. With reference to the urgent demand for free choice of physicians by the insured the government gives regulations both for the free choice of physicians and also for making contracts with special insurance physicians. The formation of contract committees, which shall serve to prevent misunderstandings and to settle such as already have arisen is provided for in the bill, and this is really of no little importance. These committees will be so much the better fitted for their task as they consist of representatives from both parties in equal numbers selected by the societies and by the physicians immediately interested in their practice. There is no doubt that the German medical profession will not be content with the improvements found in the new bill, and it is to be expected that they will engage with the same energy against the faulty provisions still remaining in this second bill as they did against the first. Their efforts must now be directed to the other legislative body, the Reichstag.

Pharmacists and Physicians

The medical council for West Prussia at a recent session resolved to ask the pharmacists' council of the province to require pharmacists not to give patients with the medicines prescribed by physicians any advertisements of other remedies.

Frequently paper containing advertisements, which is furnished to the pharmacists by the manufacturers free, is used for wrapping medicine bottles, boxes, etc. On the other hand, the pharmacists council has requested the medical council that physicians abstain from indicating a preference for a particular pharmacist, which is forbidden by law, and it also requests that physicians should write their prescriptions plainly, and in large cities have their names printed on the prescription blanks, so as to prevent injury to the pharmacists.

Pharmacology

AMERICAN DRUGGISTS SYNDICATE

The Capital Stock Is Increased and Physicians Are Invited to Come In

Since the last article[1] in The Journal dealing with the American Druggists Syndicate appeared, this cooperative "patent medicine" concern has increased its capital stock to $2,500,000. In the notice sent out by the A. D. S. calling for a special meeting of the stockholders to consider the question of increasing the stock, the statement was made that "it is our purpose to enlist the active cooperation of the honest physician, notwithstanding the opposition of the *traitorous hypocrites editing certain medical journals.*" This last clause, we believe, has a personal element. The increase in capitalization having been accomplished and a vast amount of stock created, physicians are now being appealed to, through a small pamphlet, to purchase at $10 a share the common stock of the concern. Should the "Orangeine" or "Lydia Pinkham" people ask physicians to purchase their stock and participate in the unholy profits that accrue from the sale of these nostrums the protests from an indignant profession would be no more numerous and outspoken than those which have poured in on The Journal since this A. D. S. pamphlet has reached the physicians of the country. In the booklet, which is entitled "Millionaire-Makers for Others," the A. D. S. calls attention to the vast profits that have been created from the sale of Doan's Kidney Pills, Lydia Pinkham's Compound, Swamp Root, Laxative Bromo Quinin, and other nostrums, and urges physicians to purchase stock in the American Druggists Syndicate so that a competing line of nostrums may be marketed and the physician himself get some of the profits.

SUBSTITUTION THE KEY-NOTE

There is "only one way to eliminate the nostrum evil," says the A. D. S., and that is "to make the advertising of such products unprofitable to the manufacturer." How this is to be brought about is explained in a way that must make honest druggists blush. Substitution is the method. " . . . it is only necessary to give the druggist an opportunity to offer a safe and legitimate product [that is to say an A. D. S. substitute] whenever a product of the other kind is called for." If the A. D. S. is to be believed, substitution is a widespread accomplishment: "Leading druggists are authority for the statement that they can sell such legitimate products [A. D. S. preparations] to seven out of ten who otherwise might be induced to use dangerous ones." Of the ten, the three individuals who know what they want when they want it, can be finally landed in the A. D. S. net "through intelligent literature [whatever that may be] to be given them with the packages they insist on."

Resolved to simpler terms it means that the druggist who is a member of the A. D. S. should endeavor to get the customer who wants "Antiphlogistine" to take "A. D. S. Anti-Inflammatus;" he who desires "Paine's Celery Compound" to accept "A. D. S. Celery Compound;" he who feels the need of "Bromo-Seltzer" to be satisfied with "A. D. S. Effervescent Bromo Headache Salt;" he who pines for "California Syrup of Figs" to be content with "A. D. S. Fig Syrup Compound," and she who calls for "Lydia Pinkham's," to take instead "A. D. S. Pelvitone."

THE PHYSICIAN'S PART

And where does the physician come in? If he is a stockholder in the A. D. S. he is "*given an opportunity* to share equally with druggists in the profits derived from the sale of the legitimate [?] products offered by this organization." In other words the druggist is to substitute, the public is to dope itself, and the medical profession is to participate in the financial rewards that come from such a combination.

Should the physician wonder whether this self-drugging on the part of the public would not have a financially deleterious effect on his practice he is assured that the A. D. S. remedies include "only such medicinal articles as would be least likely to conflict with the interests of physicians." Nothing is said of the fact that practically the only A. D. S. preparations advertised are its rankest nostrums: Pelvitone; Kidney Remedy; Cold and Grippe Remedy; Rheumatic Remedy, and so on. Neither is it acknowledged that should the nostrum element be eliminated from the activities of the American Druggists Syndicate the whole structure would collapse.

And the ethics of it? Well, we are told that:

> "The physician or pharmacist who allows his conception of ethics to prevent him from providing for the material wants of his family and for their future welfare by a fear of being accused of *commercialism is lacking in good judgment.*"
>
> "Old worn-out moth-eaten notions of ethics should not prevent honorable physicians and pharmacists from working in harmony for the increase of the legitimate profits of both professions."

DISPENSING PHYSICIANS, BEWARE!

An interesting sidelight, in that it contains a veiled threat, is to be found in this A. D. S. booklet. The dispensing physician is the text of the story. Such a physician, we are told, lived in a small town and, although there were two excellent drug stores, he would not write prescriptions. What happened? The druggists "held a conference and soon decided what they would do to teach the physician a lesson. They employed *a bright and competent [nothing said about honor!]* young physician to write free prescriptions and make free professional calls. It took only about three weeks to convince the first doctor on the ground that he would soon be starved out of the field if he did not make peace with the druggists." The physician, then, we are told, went to the druggists, acknowledged the error of his ways and promised to be good ever after. As the A. D. S. pamphlet adds: "This is intended only as an illustration of what could be done by pharmacists in *extreme cases, if they found it necessary,* as it was in this instance."

We presume the object of this story is to engender the same kindly feeling between physicians and druggists as must be developed between members and non-member druggists by those A. D. S. advertisements which, by inference, inform the public that the only way to be sure it is getting pure drugs is to patronize a member of the American Druggists Syndicate.

Altogether, the pamphlet, and its message to physicians, cannot be described in language more pertinent and fitting than that used by one of The Journal's correspondents, who characterized it as "truly a monumental bit of impertinence."

Correspondence

Excretion of Hexamethylenamin

To the Editor:—In The Journal, March 12, there appeared an article by Dr. Barton on the excretion of the decomposition product of hexamethylenamin by the mucous membrane of the ear. After reading this article it occurred to me that if formaldehyde is excreted by the mucous membrane of the ear, possibly it is also excreted by the mucous membrane of the bronchi, and also perhaps in the alveoli of the lungs.

To test this, I administered the drug to a patient with chronic bronchitis who happened to have at the time mucopurulent expectoration; after three doses, the character of the expectoration changed from mucopurulent to mucoid, and after six doses the quantity was very much diminished. A portion of the sputum tested after three doses had been administered gave a positive reaction in a very short time. A specimen after the sixth dose also gave a positive reaction, but only after several hours.

---

[1] Previous articles dealing with the A. D. S. have been reprinted in pamphlet form. This will be sent to those who want it. Enclose a stamped addressed envelope with request.

At my request, Dr. Percy Smith, the superintendent of the District of Columbia tuberculosis hospital, is testing it in advanced cases of tuberculosis, with the idea of checking the profuse purulent expectoration and, perhaps, of rendering it sterile. I feel that great results may possibly be obtained.

George H. Heitmuller, Washington, D. C.

The Cutaneous Reaction to Tuberculin

To the Editor:—It has been the practice at the New Mexico Cottage Sanatorium to use the Detre differential test in all our patients on admission, our purpose being to acquire data as to the reliability of the test. In connection with the cutaneous test I have several times observed a curious phenomenon and have not noticed that it has been reported heretofore. If it has not I would like to take this opportunity to record it.

Months, and in one instance a year, after the performance of the test, a dose of tuberculin will be reached which will give rise to a very slight reaction and following the reaction, or coincident with it rather, there is at once a recrudescence of all the phenomena at the sight of the old skin test, acting very much as though the individual had had a second cutaneous application of tuberculin.

E. Bullock, M.D., Silver City, N. M.

Association News

THE ST. LOUIS SESSION

Announcement of Reduced Railroad Rates Secured and Special Trains Arranged

The Committee on Transportation and Place of Session submits the following report concerning rates and trains to the St. Louis session in June:

RAILROAD RATES

The Central Passenger Association and the Western Passenger Association, which include all railway lines operating in the states of Ohio, Michigan, Indiana, Illinois, Iowa, Wisconsin, Minnesota, North and South Dakota and Missouri, will make a rate of one fare and a half for the round trip, tickets to be sold June 4 to 8, inclusive. The return limit is June 20, with provision for extension of the limit to July 20 if ticket is deposited with joint agent at St. Louis and deposit fee of $1 paid by the passenger.

The Trunk Line and New England associations, which include all lines operating in the states of Maine, Vermont, New Hampshire, Massachusetts, Connecticut, Rhode Island, New York, Pennsylvania, New Jersey, West Virginia, Delaware, Maryland and the District of Columbia, have authorized a round-trip rate of one fare and a half, tickets to be sold June 3 to 6, inclusive. The return limit is June 20, with provision for extension to July 20 by deposit of ticket and payment of deposit fee of $1.

The Trans-Continental Association has authorized a one-fare rate of $67.50 from all California points, tickets on sale June 3, 4 and 5; the return limit is three months. The same rate is to apply from North Pacific coast points in Oregon and Washington, tickets to be on sale June 2 only; the return limit is three months from date of sale.

So far, the Trans-Missouri Association, which includes lines operating in Kansas, Nebraska, Wyoming, Colorado and New Mexico, has made no reduced rates, nor have the South Western or South Eastern associations, except that the South Western has authorized a rate of a fare and a half from southern Missouri.

It is hoped that rates may yet be obtained from the territory embraced by these associations, and further announcement will be made by the committee concerning them later.

Considering the territory covered, these are the best rates which the Association has had since the two-cent laws went into effect.

SPECIAL TRAINS

The following special trains have been arranged:

A day train over the Chicago and Alton road will leave Chicago Monday, June 6 at 9 a. m., arriving at St. Louis about 5 p. m., in ample time for members to get located in their hotels for the night.

This train will be composed of reclining chair cars for those who do not wish to patronize the Pullman parlor cars, a library club car with buffet, dining car, Pullman parlor cars and observation car. This train will provide a beautiful ride through the state by daylight.

A night special will leave Chicago over the Chicago and Alton road at 11:30 p. m., arriving at St. Louis about 8 a. m. This train will consist of reclining chair cars (if desired) without extra charge, club cars with buffet and Pullman drawing-room sleeping cars.

These special trains from Chicago will stop at Joliet, Dwight, Pontiac, Chenoa, Bloomington, Atlanta, Lincoln, Springfield, Carlinville and Alton to pick up members and will make any other intermediate stops if previous notification is given that members wish to board the trains.

Members may leave Peoria at 12:20 p. m. on the Chicago and Alton, connecting with the special at Springfield.

Special trains will leave Kansas City over the Chicago and Alton road on Monday, June 6, at 9 a. m. and 11:30 p. m., the former making a day run through Missouri, arriving at St. Louis at 5 p. m., and the latter a night run, arriving at St. Louis at 8 a. m. In their makeup these trains will be the counterpart of the trains between Chicago and St. Louis and will stop at the following Missouri stations: Independence, Odessa, Higginsville, Marshall, Slater, Glasgow, Higbee, Centralia and Mexico and at intermediate points if previous notification is given that members wish to join the trains.

From Minneapolis and St. Paul a special train will be run over the Chicago, Milwaukee and St. Paul road to Chicago, and from Chicago to St. Louis over the Chicago and Alton.

A special train, or special drawing-room sleepers set aside for the exclusive use of members, will be run over the Toledo, St. Louis and Western (Clover Leaf line) leaving Toledo, Ohio, at 7:15 p. m. and arriving at St. Louis at 8 o'clock in the morning. This train will stop at Continental, Delphos and Ohio City, Ohio, and Decatur, Marion, Kokomo, Frankfort and Veedersburg, Ind., and Charleston, Ill. Stops will be made at other points if previous notification be given that members wish to take the train.

A special train, or cars as may be needed, has been arranged to run over the New York Central system, including the Boston and Albany from Boston. This train, which will stop at prominent intermediate points, will leave Boston and New York in time to reach St. Louis early Tuesday morning, June 7.

Arrangements have been made so that through tickets over the New York Central lines from Cleveland and all points east thereof may be exchanged in St. Louis at the city office of the Chicago and Alton for return trip by way of Chicago over the Chicago and Alton line, with stopover at Chicago. Likewise, tickets reading "by way of Chicago and Chicago and Alton" may be exchanged for return trip by direct route over New York Central lines.

Further information concerning reservations on any of these trains will appear in The Journal later.

M. L. Harris, Chairman,
Committee on Transportation and Place of Session.

The Section Meeting Places

The St. Louis Committee on Arrangements sends the following announcements:

The section meeting places are located on Grand avenue and on streets interesecting Grand avenue. Those meeting places located on intersecting streets are not more than 300 feet distant from Grand avenue. This distance between the extremes of the district is about one-half mile, but all are in close proximity to other halls, and special attention was given to grouping correlated sections.

The only hall that is not in the Grand avenue district is the Coliseum, where the Registration Bureau, the Commercial and Scientific Exhibits, the Postoffice, etc., will be located.

No hall in the midst of the meeting places was large enough to accommodate these departments.

The street car facilities are most excellent, cars running at two and three minute intervals, and arrangements are being made for special service on occasions when the members will travel in large bodies at any particular hour. Taxicabs will also be at hand, and a special rate will be allowed for transporting the members from the Coliseum, where the Registration Bureau will be established, to the Grand avenue district.

The section and other meeting places are as follows:

Medicine: Third Baptist Church, Grand and Washington Aves.

Surgery: Odeon Theatre, Grand and Finney Aves.

Obstetrics and Diseases of Women: Y. M. C. A. Building—Association Hall, Grand and Franklin Aves.

Laryngology and Otology: Sodality Hall, Grand Ave., between Pine and Laclede.

Ophthalmology: Aschenbroedel Hall, 3535 Pine St.

Diseases of Children: Grand Avenue Presbyterian Church, Sunday School Room, Grand and Washington Aves.

Pharmacology and Therapeutics: Delmar Avenue Congregational Church, Delmar, west of Grand Ave.

Stomatology: Y. M. C. A. Building—Small Hall, Grand and Franklin Aves.

Nervous and Mental Diseases: St. Louis University Library, *Grand Ave., head of East Pine.*

Dermatology: Odeon Bldg—Recital Hall, Grand and Finney Aves.

Preventive Medicine and Public Health: Knights of Columbus Bldg., 3549 Olive St.

Pathology and Physiology: Y. M. C. A. Building—Lecture Hall, Grand and Franklin.

Scientific and Commercial Exhibits, Postoffice, Registration Office: Coliseum, Washington and Jefferson.

President's Reception: First Regiment Armory, Grand and Manchester Aves.

General Session: Odeon Theatre, Grand and Finney Aves.

House of Delegates: St. Louis Medical Society, 3524 Pine St.

The Committee on Section Meeting Places will endeavor to have all halls fully equipped with every needed appurtenance to facilitate the transaction of the work of the sections. Communications on this subject should be addressed to Dr. H. Tuholske, Chairman of the Committee on Section Meeting Places, 609 Metropolitan Building, St. Louis.

Good Weather Probable

The Committee on Arrangements desires to assure the members that the weather in the early days of June is delightful. According to the records of the Weather Bureau the temperature for the first ten days in June varies from 70 to 80 degrees. There need be no fear of extreme heat in St. Louis during the period of the session. The Committee on Arrangements wishes this information widely disseminated.

E. J. Goodwin, Secretary,
Committee on Arrangements.

NEW MEMBERS

List of new members of the American Medical Association for the month of March, 1910:

ALABAMA

Banks, M. J., Jackson's Gap.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

DISTRICT OF COLUMBIA: Washington, April 12-15. Sec., Dr. George C. Ober, 125 B St., S. E.

ILLINOIS: Chicago, April 14-16. Sec., Dr. J. A. Egan, Springfield.

NEW MEXICO: Santa Fe, April 11-12. Sec., Dr. J. A. Massie.

OKLAHOMA: Ione Hotel, Guthrie, April 12. Sec., Dr. Frank P. Davis, Enid.

WEST VIRGINIA: Wheeling, April 12-14. Sec., Dr. H. A. Barbee, Point Pleasant.

New Buildings at McGill University

The new buildings to be occupied by the Medical Faculty of McGill University which are being erected to replace those destroyed by fire in 1907 are rapidly nearing completion. They will cost $750,000 and are located near the old medical buildings on a site which was given to the university by Lord Strathcona, the chancellor of McGill University, who has *contributed more than half of the cost of the new buildings.* An interesting program has been arranged for the ceremonies with which the buildings are to be inaugurated, June 6 and 7, at which the Governor General of Canada will officiate.

It has been determined to mark the occupation of the new buildings by a reunion of as many as possible of the physicians who have graduated from McGill. Communications from representatives of each of the 45 classes indicate there will be a unique gathering of McGill graduates from all parts of the world in Montreal, June 6 and 7.

The Public Service

Medical Department of the Army

Changes for the week ended April 2, 1910:

Banister, William B., lieut. col., will, in addition to his present duties at Fort Snelling, take charge of the office of chief surgeon, St. Paul, Minn., making not to exceed three trips per week to St. Paul and return to Fort Snelling, Minn.

Glennan, *James D., lieut. col.*; Ashburn, Percy M., major, appointed members of an Army retiring board to meet at San Francisco.

Birmingham, H. P., lieut. col.; McCaw, Walter D., lieut. col.; Darnall, Carl R., major, appointed members of a board to meet at the Army Medical Museum Bldg., this city, for the physical examination of candidates for appointment and Second Lieutenants.

Mills, R. H., dental surgeon, reported for temporary duty, Plattsburg Barracks, N. Y.

Whitcomb, C. C., capt., relieved from duty at Fort Wingate, N. Mex., and ordered to duty at Medical Supply Depot, New York City.

Whitmore, Eugene R., major, the detail of, on temporary duty in the Bureau of Science, Department of the Interior, P. I., is further extended to Aug. 15, 1910.

Casaday, George H., dental surgeon, returned to Presidio of Monterey, Cal., from leave of absence.

Flynn, Thomas J., 1st lieut., M. R. C., ordered to proceed from Fort Ethan Allen, Vt., to Madison Barracks, N. Y., for temporary duty.

Scott, Minot E., dental surgeon, ordered to proceed from Vancouver Barracks, Wash., to Fort Stevens, Ore., and Fort Columbia, Wash., for temporary duty.

Johnson, Charles W., 1st lieut., M. R. C., honorably discharged from the service of the United States.

Ashburn, James K., 1st lieut., M. R. C., honorably discharged from the service of the United States, to take effect April 4, 1910.

Rutherford, Henry H., major; Jones, Percy L., capt.; Metcalfe, Raymond F., capt.; Farrow, Edgar J., 1st lieut., M. R. C.; Tetrault, Charles A., 1st lieut., M. R. C., relieved from duty in Philippines Division, and will proceed on transport to sail from Manila, P. I., July 15, to San Francisco, and on arrival to report by telegraph to the Adjutant General of the Army, for further orders.

Bierbower, Henry C., 1st lieut., M. R. C., granted 3 months' leave on arrival at station in the United States.

Maynard, Edward B., 1st lieut., M. R. C., recently appointed, ordered to Fort Snelling, Minn., for duty.

Ingalls, R. E., dental surgeon, reported for duty at Fort Douglas, Utah.

Hull, Alva R., 1st lieut., M. R. C., relieved from duty at Fort Sam Houston, Texas, to take effect about April 12, 1910, and will then proceed to his home. Lieutenant Hull is relieved from active duty in the Medical Reserve Corps, on his arrival at his home.

Holland, Josiah H., 1st lieut., M. R. C., relieved from duty at Fort Barrancas, Fla., and ordered to Fort Douglas, Utah, for duty.

McCown, Thomas B., 1st lieut., M. R. C., relieved from duty at Fort Douglas, Utah, and ordered to Fort Barrancas, Fla., for duty.

Coffey, A. McD., 1st lieut., M. R. C., ordered to accompany Co. I, Signal Corps, from Sam Houston, Texas, to San Francisco, and on completion of this duty to proceed to his home.

Smith, Allen M., major, ordered to accompany the 9th Infantry from Sam Houston, Texas, to San Francisco, and on completion of this duty to return to his home.

McAndrew, P. H., major, granted 5 days' leave of absence.

McDonald, R. C., 1st lieut., M. R. C., recently appointed, is ordered to Fort Sam Houston, Texas, for duty.

Medical Corps of the Navy

Changes ordered March 21, 1910:

Diehl, O., med. inspector, detached duty as fleet surgeon, Asiatic Fleet, on *Charleston*, and continue other duties.

Shipp, E. M., surgeon, detached duty Naval Hospital, Philadelphia; to duty Navy Recruiting Station, New York.

Wilson, G. B., surgeon, detached duty *Wabash*, Navy Yard, Boston; to duty as fleet surgeon, U. S. Asiatic Fleet, on *New York*.

Ryder, C. E., P. A. surgeon, detached duty New York Nautical Training Ship *Newport*, to Naval Medical School, Washington, D. C., for instruction.

Dunn, H. A., P. A. surgeon, detached duty Naval Proving Ground, Indian Head, Md.; to Naval Medical School, Washington, D. C., for instruction.

Payne, J. H., P. A. surgeon, detached duty Naval Hospital, New York; to Naval Medical School, Washington, D. C., for instruction.

Seaman, W., P. A. surgeon, detached duty Naval Recruiting Station, New York; to Naval Medical School, Washington, D. C., for instruction.

Fauntleroy, A. M., P. A. surgeon, detached duty *New York* and *Indiana;* to duty Naval Hospital, Naval Home, Philadelphia.

Stepp, J., P. A. surgeon, detached duty *Franklin*, Navy Yard, Norfolk, Va.; to duty Naval Medical School, Washington, D. C., for instruction.

Tolfree, H. M., P. A. surgeon, detached duty Naval Magazine, Iona Island, N. Y.; to duty Naval Medical School, Washington, D. C., for instruction.

Cather, D. C., P. A. surgeon, detached duty Navy Recruiting Station, Kansas City, Mo.; to home and granted leave 1 month.

Warner, R. A., P. A. surgeon, detached duty Naval Hospital, Norfolk, Va.; to duty New York Nautical Training Ship *Newport*.

Hayden, R., asst.-surgeon, to duty Naval Proving Ground, Indian Head, Md.

Kerr, W. M., asst.-surgeon, detached duty Naval Training Station, Newport, R. I.; to duty Naval Station, Guam, M. I.

Lawrence, H. F., asst.-surgeon, detached duty Naval Station, Tutuila, Samoa; to home and wait orders.

Valz, E. V., asst.-surgeon, detached duty *Mississippi;* to examination for promotion, Washington, D. C., and on completion wait orders.

Stibbens, F. H., asst.-surgeon, detached duty *Pennsylvania;* to examination for promotion, Washington, D. C., and on completion wait orders.

Rhoades, G. C., asst.-surgeon, detached duty *Scorpion;* to home and wait orders.

The following are detached from duty at Naval Medical School, Washington, D. C., and ordered as follows:

Connor, W. H., acting asst.-surgeon, to duty Naval Station, Tutuila, Samoa.

Camerer, C. B., acting asst.-surgeon, to duty Naval Hospital, Norfolk, Va.

Riddick, W. J., acting asst.-surgeon, to duty Naval Medical School Hospital, Washington, D. C.

Phillips, E. W., acting asst.-surgeon, to duty Naval Hospital, New York.

Thompson, F. W., acting asst.-surgeon, to duty Navy Recruiting Station, Kansas City, Mo.

McMullin, J. J. A., acting asst.-surgeon, to duty Naval Magazine, Iona Island, N. Y.

French, G. R. W., acting asst.-surgeon, to duty Naval Hospital, Mare Island, Cal.

Irvine, W. L., acting asst.-surgeon, to duty Naval Training Station, Narragansett Bay, R. I.

Davidson, A. B., acting asst.-surgeon, to duty Naval Hospital, Mare Island, Cal.

Jenkins, H. E., acting asst.-surgeon, to duty *Franklin*, Navy Yard, Norfolk, Va.

Robbins, I. W., acting asst.-surgeon, to duty *Pennsylvania*.

Walton, D. C., acting asst.-surgeon, to duty *Scorpion*.

Thomas, G. E., acting asst.-surgeon, to duty *Wabash*, Navy Yard, Boston, Mass.

Bass, J. A., acting asst.-surgeon, to duty *New York*.

Robertson, G. E., acting asst.-surgeon, to duty *Mississippi*.

Changes for the week ended March 26, 1910:

Von Wedekind, L. L., surgeon, detached from the Naval Recruiting Station, Chicago, and ordered to command Naval Hospital, Annapolis, Md.

Grieve, C. C., P. A. surgeon, detached from the Naval Hospital, Norfolk, Va., and ordered to the Naval Recruiting Station, Chicago.

Kuder, W. S., P. A. surgeon, resignation accepted, to take effect April 1, 1910.

Whitmore, G. B., asst.-surgeon, detached from the *Wisconsin* and ordered to duty in connection with fitting out the *Delaware*, and to duty on board that vessel when placed in commission.

Dodge, A. H., asst.-surgeon, detached from the Naval Hospital, Las Animas, Colo., and ordered to the *California*.

Bloerdorn, W. A., acting asst.-surgeon, detached from the Naval Medical School, Washington, D. C., and ordered to the Naval Hospital, Las Animas, Colo.

Hart, S. D., acting asst.-surgeon, detached from the Naval Medical School, Washington, D. C., and ordered to the Asiatic Station.

Cecil, A. B., acting asst.-surgeon, detached from the Naval Medical School, Washington, D. C., and ordered to the *Wisconsin*.

Public Health and Marine-Hospital Service

Changes for the week ended March 30, 1910:

Mead, F. W., surgeon, directed to proceed to Tampa and Port Tampa City, Fla., on special temporary duty.

Carter, H. R., surgeon, leave of absence for 1 month from March 11, 1910, on account of sickness, amended to read 9 days from March 11, 1910, on account of sickness.

Wasdin, Eugene, surgeon, granted 2 months' leave of absence from March 22, 1910.

White, J. H., surgeon, granted 14 days' leave of absence from April 1, 1910.

Lavinder, C. H., P. A. surgeon, granted 4 days' leave of absence en route to Germany.

Lumsden, L. L., P. A. surgeon, directed to proceed to Omaha, Neb., on special temporary duty.

Anderson, John F., P. A. surgeon, directed to proceed to Charlottsville, Va., on special temporary duty.

Fricks, L. D., P. A. surgeon, relieved from duty at Fort Stanton, N. Mex., and directed to proceed to Mobile Quarantine Station, Ala., and assume command.

Korn, W. A., P. A. surgeon, on being relieved by Passed Assistant Surgeon Charles W. Vogel, directed to proceed to Stapleton, N. Y., and report to the medical officer in command for duty and assignment to quarters.

Vogel, Charles W., P. A. surgeon, relieved from duty at Stapleton, N. Y., and directed to proceed to Reedy Island Quarantine Station, Del., and assume command.

de Valin, Hugh, P. A. surgeon, relieved from command of Mobile Quarantine Station, Ala., and from temporary duty at the Hygienic Laboratory, and directed to proceed to Havana, Cuba, for duty in the office of the Consul-General.

Hasseltine, H. E., asst.-surgeon, relieved from duty at Buffalo, N. Y., and directed to proceed to Seattle, Wash., and report to the commanding officer Revenue-Cutter *Rush* for duty.

Leake, James P., asst.-surgeon, granted 4 days' leave of absence from March 18, 1910, on account of sickness.

Knight, Carlisle P., asst.-surgeon, directed to proceed to Buffalo, N. Y., and report to the medical officer in command for duty.

Flinn, Thomas, W. P., acting asst.-surgeon, granted 20 days' leave of absence from April 1, 1910.

Hamilton, H. J., acting asst.-surgeon, granted 2 days' leave of absence from March 23, 1910.

Knight, Carlisle P., commissioned Assistant-Surgeon March 16, 1910.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

THE WASSERMANN REACTION

To the Editor:—Please give me a complete list of articles on the Wassermann reaction. R. A. Weston, M.D., Des Moines, Iowa.

Answer.—As hundreds of articles have appeared on this subject, it is impossible to give a complete list here. Practically all these articles were listed, as they appeared, in The Journal's department of Current Medical Literature, and in the Index to Subjects which is published in The Journal every six months, in the last number of the volume. The following are some of the more valuable and recent ones taken from the Index. Most of those published in The Journal have full bibliographies in the footnotes:

Schaudinn and Hoffman: Arb. a. d. k. Gsndhtsamte, 1905, xxii, 835.

Wassermann: *Berl. klin. Wchnschr.*, 1907, xliv, 12.

Nonne: Clinical Diagnosis of the Syphilogenous Diseases of the Nervous System, The Journal, July 24, 1909, p. 289.

Sachs: The Wassermann Reaction in Relation to Diseases of the Nervous System, The Journal, Sept. 18, 1909, p. 929.

Noguchi: Serodiagnosis of Syphilis, The Journal, Sept. 18, 1909, p. 935.

Castelli: The Wassermann Reaction, The Journal, Sept. 18, 1909, p. 936.

Noguchi: A Rational and Simple System of Serodiagnosis of Syphilis, The Journal, Nov. 6, 1909, p. 1532.

Wieder and L'Engle: Studies of the Precipitin Tests for Syphilis, The Journal, Nov. 6, 1909, p. 1535.

Litterer: Serodiagnosis of Syphilis, The Journal, Nov. 6, 1909, p. 1537.

Harris and Corbus: Clinical Value of the Spirochæta Pallida in Diagnosis and Treatment of Syphilis, The Journal, Dec. 5, 1908, p. 1928.

Neilsen: *Monatsh. f. pract. Dermat.*, xlviii, No. 2, p. 5.

Fleischmann and Butler: Serum Diagnosis of Syphilis, The Journal, Sept. 14, 1907, p. 934.

Plaut, Fornet and Schereschewsky: Serodiagnosis of Syphilis, Tabes and paralysis, *München. med. Wchnschr.*, July 23, 1907; abstr. in The Journal, Sept. 28, 1907, p. 1154.

Citron: Serodiagnosis of Syphilis, *Berl. klin. Wchnschr.*, Oct. 28, 1907; abstr. in THE JOURNAL, Dec. 7, 1907, p. 1962.

Butler: Serum Diagnosis of Syphilis, *New York Med. Jour.*, Nov. 30, 1907; abstr. in THE JOURNAL, Dec. 14, 1907, p. 2037.

Harris and Corbus: Parasitology of Syphilis, THE JOURNAL, Sept. 4, 1909, p. 757.

Texas, State Medical Association of, Dallas, May 10-12.

ASSOCIATION OF AMERICAN MEDICAL COLLEGES

Twentieth Annual Meeting, held at Baltimore, March 21-22, 1910
(Continued from page 1158)

Report of Judicial Council

In connection with the several reports recently made on the standing of medical colleges, the council recommended that it be given authority to order an investigation of the colleges in membership that were reported on adversely by other organizations, and to investigate any other colleges in membership that may be subject to like criticism; further, that these investigations be made by two persons selected by the council, that the expense of such investigation be borne by the college inspected, and that other educational bodies interested in examining colleges be invited to participate in such inspection and examination. The council recommended the acceptance of the applications of the Tulane University Medical Department, and Harvard University Medical Department. Application for membership was made by the Medical Departments of the University of Vermont and Syracuse University, but inasmuch as these applications were received during the session, too late for inspection of these colleges, no action could be taken.

Report of Committee on Medical Education

The committee endorsed the present system of matriculation record blanks and urged a faithful compliance with the present entrance standards on the part of all the colleges in membership. The committee also recommended that the present entrance standard be increased as soon as practicable, and urged that the state medical examining boards and the various state educational bodies make an earnest effort to raise the standard in their respective states, so that these will be at least the equal of the association standards. The committee emphasized the importance of recognition of the standard public high school and asked that the colleges in membership lend their influence and support to a high school educational basis. The combined baccalaureate and medical course now given by many universities was endorsed. The committee also recommended that there be submitted at the next annual meeting a curriculum for the five-year medical course. The concentration plan of teaching was recommended as a correct pedagogic principle, and the association was urged to place itself on record as favoring this plan and to instruct the committee to arrange an outline for a curriculum based on the concentration plan of teaching.

Report of Committee on Medical Research

The committee called attention to the rules recommended by a committee of the American Medical Association, and urged that this association concur in the recommendations of the American Medical Association committee, and that these rules be posted in all laboratories where animal experimentation is carried on and also that individuals performing animal experimentation should comply not only with the letter but the spirit of these rules.

Report of Committee on Equipment

The Committee on Equipment did not amend the report made in 1909, but urged that the colleges adhere as closely as possible to the equipment standard prepared by the secretary and adopted by the association in 1908.

Report of Committee on Curriculum

This committee recommended a four-thousand-hour schedule without any allowable diminution; the number of scheduled hours to represent the actual number of hours scheduled for each student. While the distribution of time between didactic and laboratory instruction in the laboratory subjects was recommended, the committee did not regard it as possible to distribute the time in the clinical subjects among the various kinds of exercises. Such distribution was left to the good judgment of the college authorities, to be arranged to suit their individual conditions. The committee recommended, however, that not more than one-half the time devoted to any subject should be devoted to clinical and didactic work, and that at least one-half of the time should be devoted to section or individual work. The schedule recommended by the committee is based on a course extending over thirty-two weeks, of which thirty weeks shall consist of actual teaching, and two weeks be allotted to examinations. The hours assigned are not to be considered "credit" hours. The committee considered it unwise to regulate courses too much in detail, and submitted the following curriculum for consideration as a constitutional amendment at the next annual meeting:

REPORT OF COMMITTEE OF CURRICULUM, ADOPTED MARCH 22, 1910

	Total Hours.	Lect. Rec. Dem.	Lab. Work.
DIVISION I. ANATOMY—720 Hours (18 Per Cent.)			
(a) Gross Anatomy (including Applied Anatomy)	510	120	390
(b) Histology and Mic. Anatomy	135	30	105
(c) Embryology	75	30	45
DIVISION II. PHYSIOLOGY AND CHEMISTRY—600 Hours (15 Per Cent.):			
(a)	180	60	120
(b)	75	30	45
(c)	105	30	75
(d)	240	165	75
DIVISION III. PATHOLOGY, BACTERIOLOGY AND HYGIENE—450 Hours (11.25 Per Cent.):			
(a) Bacteriology	135	30	105
(b) Hygiene and General Diet	45	45	...
(c) Pathology	270	60	210

DIVISION IV. PHARMACOLOGY, MATERIA MEDICA AND THERAPEUTICS—240 Hours (6 Per Cent.):

(a) Pharmacology	105	40	65
(b) Materia Medica and Pharmacology	80	...	...
(c) Therapeutics	55	...	...

DIVISION V. MEDICINE AND MEDICAL SPECIALTIES—970 Hours (24.25 Per Cent.):

(a) General Medicine (including Clinical Microscopy)	640	...	...
(b) Pediatrics	150	...	...
(c) Nervous and Mental Diseases	105	...	...
(d) Jurisprudence, Ethics and Economics	30	...	...
(e) Dermatology and Syphilis	45	...	...

DIVISION VI. SURGERY AND SPECIALTIES—720 Hours (18 Per Cent.):

(a) General Surgery	510	...	...
(b) Orthopedics	45	...	...
(c) Genitourinary Diseases	45	...	...
(d) Eye	60	...	...
(e) Nose, Ear, Throat	60	...	...

DIVISION VII. OBSTETRICS AND GYNECOLOGY—300 Hours (7.5 Per Cent.):

(a) Obstetrics	195	...	...
(b) Gynecology (including some Abdominal Surgery)	105	...	...

Fifteen of the 640 hours in medicine are designed for the teaching of dietetics as applied to diseased conditions—practical dietetics. Fifteen of the 45 hours allotted to hygiene are to be devoted to the consideration of the more fundamental principles of dietetics. The allowance for pediatrics is intended to include instruction in the exanthemata. The surgery peculiar to children may be given from the chair of pediatrics or from the chair of surgery. Instruction in surgery should be confined to what the general practitioner needs. More special work should be provided for by advanced or postgraduate courses. The time allotted to obstetrics does not include the time spent in the care of confinement cases. The committee recommended that each student should personally manage at least five cases. The relations of gynecology and surgery were considered, but the committee did not attempt the solution of the problem. In case gynecology does not include any abdominal surgery, or very little of it, the committee recommended that the whole or a part of sixty hours should be transferred to surgery. The committee recommended that more attention be paid to the teaching of economics.

Advancement of Medical Education

DR. G. MILTON LINTHICUM, Medical and Chirurgical Faculty of Maryland: The highest ideals of modern medicine are not being striven for in a practical way. The science of eugenics does not receive the attention it deserves. The physician is in a better position to understand the causes and factors which produce departure from the normal than is any other trained scientist. The large medical schools, with equipment and means, associated with large and diverse hospital advantages, must investigate moot questions and the application of newer scientific theories in the treatment of disease. Progress and evolution in medicine must be met by adequate provision by teaching institutions. The segregated, independent, and unendowed institutions cannot meet the conditions which are essential. Medical training has grown more expensive with a correspondingly diminishing income from students, and to meet expenses money must be derived from other sources. The lengthening of the medical course has, in my opinion, reached the point beyond which it is unsafe to go; it is contrary to the economics of human life to lengthen the time for medical training beyond four years. I can see no reason why the vacation period should not be shortened and thus the time of instruction increased in each of the four years.. I do not regard the college degree as an essential requirement for admission, as it may carry with it only literary training, which in itself is doubtless of value and yet is not commensurate with the value of time spent in obtaining it. Teachers find that the high-school graduate grasps details and observes with more precision than the student who has spent several years in a purely literary pursuit. If the professional course must be lengthened, it should be backward into the college course. The teaching of anatomy, biology, chemistry, physiology and botany should be a part of the college preparatory course, and should be dealt with in the medical school only in relation to research and clinical application. This would relieve the curriculum without lengthening the medical course. The other alternative is to teach such subjects in the first year of the medical course, increasing the course to five years.

Concentration Plan of Teaching

DR. HENRY A. CHRISTIAN, Harvard Medical School: Concentration is employed in two portions of the medical curriculum at Harvard; each differs somewhat from the other and concerns divergent subjects. The first group includes the subjects of the first year and a half; anatomy, histology, embryology, physiology, biologic chemistry, bacteriology and pathology (including neuropathology and surgical pathology). These subjects are so arranged that the student studies only two of them in a given period of time. The student occupies his forenoons with one subject and his afternoons with another, with the exception of one month of the first year, in which the entire day is devoted to anatomy, and two months of the second year in which the entire day is devoted to pathology. Each group of two subjects is completed and the examination held before new subjects are begun. Anatomy, histology and embryology are taught during the first half of the first year; physiology and biologic chemistry are taught during the second half of the first year; bacteriology and pathology are taught during the first half of the second year. The second portion of the curriculum to which the concentration plan is applied at Harvard includes all the subjects of the fourth year. This work is entirely elective, while all work up to that time is prescribed. Each elective course consists of one month's work, occupying a minimum of 125 hours. Usually but a single subject is studied in a given month and not more than two subjects may be studied at one time. The student elects which plan he will pursue. The concentration plan is not used during the second half of the second year, nor during any part of the third year. That portion of the curriculum is devoted to the preliminary and more general study of medicine, surgery, obstetrics, pharmacology, therapeutics, and the specialties. The concentration plan for the first year and a half has been in operation practically unmodified for ten years, and the fourth year elective system for five years.

For the occasional student this system is manifestly an advantage. The regular student has the opportunity to choose his own instructor, which is an advantage, as the student gets much from the personality of the teacher, and when the teacher is personally agreeable, this is accentuated. Again, it allows the student to balance up his work. The expression of opinion from the teachers is very strongly in favor of the fourth year electives as a general plan. As a result of experience, the Harvard faculty is in favor of the concentration plan throughout, and of the elective plan in the fourth year. A too rigid application of concentration teaching is not believed to be best suited to the medical student of to-day. More modification of the plan in application to anatomy seems desirable than for other subjects, as there is less satisfaction expressed with the present concentration teaching of anatomy than with the other subjects. I regard the concentration plan with favor as a system, but believe it should be modfied slightly to increase its elasticitiy and particularly that in applying the concentration plan of study a course should not end abruptly, but certain correlated exercises should be continued after the main facts of a subject have been acquired by concentration study. The amount of modification made should vary with the different subjects of study, and should be adapted to the local conditions of each institution.

DISCUSSION

DR. F. M. BRIGGS, Tufts College Medical School: The concentration plan has been tried at Tufts, and found very successful. We carry it through the entire second year, teaching pharmacology, materia medica, therapeutics and physiologic chemistry in the second semester of the second year. The fourth year is only partly elective, which we think a much better way. We require clinical medicine and clinical surgery of all third and fourth year students, so that they will have had the experience which every general practitioner should have. The elective subjects are given at the end of the fourth year.

The College Association Standard

Mr. Abraham Flexner, Carnegie Foundation for Advancement of Teaching: The rules of the association very properly state that the entrance standing shall be the minimum requirement for admission to the medical course. An admission standard is required in order to insure a minimum degree of maturity and fitness prior to the student's beginning his medical education. The medical curriculum is constructed in content and arrangement on the supposition that students who undertake to master it have enjoyed the education in question, and therefore enter the medical school with a preliminary equipment in knowledge and power. The educational question, whatever it may be, must have been received prior to the beginning of the medical course. It is the manifest intention that a four-year high school standard should be upheld by the colleges. At best, it is not altogether satisfactory. A number of the colleges in membership are operating on a standard in advance of the minimum requirement of the association. Unfortunately, colleges that are on a high school basis do not, as a rule, enforce this standard, because they permit admission with conditions amounting to not more than six points. Such a concession is unwise, because the first year in a medical school is an extremely arduous one. Add to this the necessity of removing conditions to the extent of six points, and the result is apparent. Students not infrequently are allowed to remove these conditions some time during the college course. In New York state a uniform four-year high school matriculation basis is assured, but the actual standard of any institution is the minimum basis on which it is willing to admit students. The words "accredited" or "approved" high school differ in meaning in different parts of the country. Ordinarily, it means a high school that has been officially recognized by some competent educational authority. In New England this authority is the New England College Entrance Certificate Board. In the middle west it is the North Central Association of High Schools and Secondary Schools. In the various states the state university authorities determine the high school standing. No high school that is not mentioned in one of these lists is accredited or approved, and members of this association cannot, without violating the constitution, accept the diploma of a high school that is not on one of these lists. In many states the state board of examiners, the state superintendent of public instruction or his deputy, or an examiner selected by the college pass on the entrance credentials in rather a perfunctory manner, with the result that students are admitted in some instances with no more than a two-year high-school education. A teacher connected with a local preparatory school may be the examiner and, if the student is deficient, this teacher will act as his tutor. The weakest showing is made by the certificates from reputable instructors, accepted in lieu of some board examination. The registration offices of every well-conducted academic institution have at hand all the data necessary to pass intelligently on any set of credentials. It seems to me that this association would do well to throw the entire question into the hands of such institutions without prejudice to the interests of any medical school that actually wishes to enforce the standard. In many states, the state university could properly perform this duty; elsewhere, an equally suitable arrangement could be made with an endowed institution. A state that desires to enforce a four-year high-school requirement could specify as satisfying its requirements a certificate of admission to a state university requiring a four-year high-school education, a certificate of admission to any institution that is a member of the Association of American Universities, or an institution on the accepted list of the Carnegie Foundation for the Advancement of Teaching, a certificate of the Regents of the University of the State of New York, or a certificate by the College Entrance Examination Board for fourteen points. Personally, I am persuaded that just now the association would be unwise to raise its standards, although particular institutions may do as they please. They deserve to be encouraged to go ahead. The general situation now needs order, organization, real values more than anything else. There must be secured an actual four-year high-school standard.

(To be continued)

Marriages

Overton Brooks, M.D., to Miss Emilgene Wortsman, both of Chicago, recently.

Eugene S. Talbot, M.D., Jr., to Miss Della Boardman, both of Chicago, March 29.

Daniel S. Hager, M.D., to Miss Mary Nicholas, both of Downers Grove, Ill., March 28.

Leopold Kaffie, M.D., Natchitoches, La., to Miss Jeannette Weil of Corpus Christi, Texas, March 15.

Halvor Larson Harley, M.D., Williamstown, N. J., to Miss Alice Robison of Milesburg, Pa., March 28.

Winfield H. Ammarell, M.D., Pittsburg, Pa., to Miss Anna E. Wicklein of Gibraltar, Pa., March 21.

William Otto Pauli, M.D. Cincinnati, Ohio, to Miss Winifred Helen Weeks of Toronto, Ont., March 29.

Frederick William Valkenaar, M.D., to Miss Reka L. Hofmeister, both of Chancellor, S. D., March 2.

Deaths

Jonathan Edwards Tefft, M.D. Medical College of Ohio, Cincinnati, 1865; acting assistant surgeon, U. S. Army in 1862, and later assistant surgeon of the First Arkansas Volunteer Cavalry during the Civil War; a member of the American Medical Association; president of the Missouri State Medical Association in 1871; president of the Southwest Missouri Medical Society in 1880, and of the Springfield Society in 1886; a member of the Mississippi Valley Medical Association; a member of the board of education of Springfield from 1871-1874, and president of the board for two years; lecturer on genitourinary surgery in the University of Missouri, Columbia, from 1878-1886; senior surgeon to St. John's Hospital, Springfield, since 1890; division surgeon to the Kansas City, Fort Scott and Memphis Railroad since 1881, and consulting surgeon to the Frisco System since 1890; surgeon to the Children's Home; one of the most widely known practitioners of southwest Missouri; died at his home in Springfield, March 25, from cerebral hemorrhage, aged 73.

Oscar C. DeWolf, M.D. New York Medical College, New York City, 1858; Medical Department of the University of France, Paris, 1860; from 1877-1889, health commissioner of Chicago; of national prominence in sanitary matters; the first commissioner of health to cause warning cards to be placed on houses where contagious disease existed; during whose administration house-to-house vaccination was first thoroughly enforced; assistant surgeon of the First Massachusetts Cavalry and surgeon of the Second Massachusetts Cavalry and the Reserve Brigade during the Civil War; formerly a member of the many learned societies; professor of surgical pathology in the Medical School of the University of Ohio, and later professor of state medicine and public hygiene in the Northwestern University Medical School; died at his home in Chester Center, Mass., March 28, from cerebral hemorrhage, aged 74.

David McComb Devendorf, M.D. College of Physicians and Surgeons, New York City, 1861; formerly a member of the Medical Society of the State of New York; and president of the Herkimer County Medical Society; for several months a surgeon in the U. S. Army General Hospital, Washington, D. C., during the Civil War; at various times, president, health officer, village trustee, and member of the municipal commission of Herkimer, N. Y.; died at the Fort Dalas Hotel, Miami, Fla., March 22, from paralysis, aged 73.

Montgomery Bottom, M.D. Hampden Sydney Medical College, Richmond, Va., 1849; for nearly half a century a practitioner at Breckenridge, Mo.; formerly a member of the American Medical Association; president of Caldwell County Medical Society and Grand River District Medical Society; president of the Breckenridge Board of Education from 1868-1888; a member of the Virginia legislature in 1853; died at his home in Breckenridge, March 20, from nephritis, aged 81.

James Wray Bailey, M.D. Atlanta (Ga.) Medical College, 1860; vice-president of the American Medical Association in 1888; a member of the Medical Association of Georgia; formerly president of the State Board of Medical Examiners and of the Hall County Medical Society; a surgeon in the Confederate Service during the Civil War; for many years vice-president of the State Banking Company, Gainesville; died at his home in that city, March 24, aged 71.

Ella Louisa Dexter, M.D. Woman's Medical College of Pennsylvania, 1881; a member of the Massachusetts Medical Society; the New England Ophthalmological Society; New England Hospital Medical Society; ophthalmologist to the New England Hospital for Women and Children, Boston, and to the Pope Dispensary; died at her home in Chestnut Hill, Boston, February 3, from rheumatic arthritis, aged 52.

Francis W. Patterson, M.D. Medical College of Ohio, Cincinnati, 1859; University of Maryland, Baltimore, 1889; a member of the Medical and Chirurgical Faculty of Maryland; and a surgeon in the Confederate service during the Civil War; for a time United States Inspector of contagious diseases of animals; died at his home in Catonsville, Baltimore, March 22, from senile debility, aged 74.

Alfred Nelson Beach, M.D. Bellevue Hospital Medical College, 1870; of Cooperstown, N. Y.; for several years surgeon on steamships running between San Francisco and China; at one time a member of the general assembly of New York, and for two years police surgeon of New York City; died in Thanksgiving Hospital, Cooperstown, N. Y., March 10, from general breakdown, aged 61.

Henry J. Beyerle, M.D. Philadelphia College of Medicine and Surgery, 1851; in 1862 a member of the Indiana legislature; for 45 years a resident of Goshen, Ind.; for more than 30 years editor and proprietor of the *Goshen Times;* for 4 years a member of the city council and for two terms a member of the school board; died at his home, March 24, from senile debility, aged 86.

James Mitchell Blackford, M.D. Starling Medical College, Columbus, Ohio, 1865; a member of the Ohio State Medical Association; mayor of Martins Ferry, Ohio, in 1906; a member of the local school board for nine years; charter member of the Martins Ferry Hospital Association, and a director of the institution; died at his home, March 26, from senile debility, aged 72.

George M. Bazemore, M.D. University of Nashville, Tenn., 1861; Bellevue Hospital Medical College, 1874; a member of the Tennessee State Medical Association; for many years local surgeon at Cleveland for the Southern Railway; chairman of the Cleveland Board of Health; died at his home, March 24, from heart disease, aged 76.

Jefferson L. Thorpe, M.D. Washington University, St. Louis, 1886; a member of the American Medical Association; local surgeon at Jefferson City for the Missouri Pacific, Missouri, Kansas and Texas, and Chicago and Alton railroads; a member of the Cole County Board of Health; died at his home, March 22, from uremia, aged 47.

Gardner Perry Pond, M.D. University of California, San Francisco, 1893; a specialist on diseases of the eye, ear, nose and throat of San Francisco for several years, and later a resident of Los Angeles county; formerly a member of the American Medical Association; died at his home in Pasadena, March 19, aged 41.

Hector H. Goodman, M.D. University of Maryland, 1881; for three years surgeon to the Baltimore Police Department; and for 25 years medical director of the Baltimore Life Insurance Company; died in the Hebrew Hospital in that city, March 20, from cerebral meningitis, following an operation on the nose, aged 60.

George M. Bell, M.D. University of Michigan, Ann Arbor, 1870; Chicago Medical College, 1871; Bellevue Hospital Medical College, 1875; for more than 40 years a practitioner of Benton Harbor, Mich.; died March 27, at the University Hospital, Chicago, from cancer of the spleen, aged 61.

Henry A. C. Poppenhusen, M.D. University of Pennsylvania, Philadelphia, 1894; formerly city physician of Washington, Mo., and coroner of Franklin county; died at his home in Hermann, March 14, from the effects of carbolic acid, believed to have been taken with suicidal intent, aged 41.

George W. Carroll, M.D. Kentucky School of Medicine, Louisville, 1868; of Smithsonia, Ala.; a member of the Medical Association of the State of Alabama and a Confederate veteran; fell from a train near Barton, Ala., March 26, and died from his injuries a short time later, aged 70.

Roland C. Irving, M.D. Bellevue Hospital Medical College, 1877; a member of the Broome County Medical Society and Binghamton Academy of Medicine; first lieutenant and assistant surgeon, First Infantry, N. G., N. Y.; died at the home of a friend in Binghamton, March 17, aged 50.

Elisha Fenn, M.D. Bellevue Hospital Medical College, 1887; of New York City; a member of the Medical Society of the State of New York; for several years a member of the Seventh Regiment; died in Roosevelt Hospital, New York City, March 26, from pneumonia, aged 57.

Thomas J. Norris, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1874; a member of the American Medical Association, and organizer of the first medical society in Macon county, Mo.; a Confederate veteran; died at his home in Macon, March 23, aged 72.

Albert V. Ellershaw, M.D. Jefferson Medical College, 1891; a member of the Medical Society of the State of Pennsylvania; and formerly a practitioner of Norristown and Bridgeport, Pa.; died at the home of his father in Blackpool, England, recently.

Leslie Teasdale Pease, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1878; a member of the Illinois State Medical Society; a member of the council of Cisco; and a member of the school board for many years; died at his home, March 15, aged 57.

Harry Ellis Clemson, M.D. University of Maryland, Baltimore, 1894; a member of the American Medical Association; medical director of the Silver Cross Home for Epileptics, Port Deposit, Md.; died at his home, March 21, from heart disease, aged 37.

William Wallace Cole, M.D. Jefferson Medical College, 1869; a member of the Medical Society of the State of Pennsylvania; a veteran of the Civil War; assistant city physician of Pittsburg; died at his home, March 25, from heart disease, aged 67.

Samuel Jay Holliday, M.D. Northwestern Medical College, St. Joseph, Mo., 1882; a member of the American Medical Association; formerly of Pollock, Mo.; died at his home in Pennville, Mo., March 2, from lobar pneumonia, aged 53.

Joseph Dawson, M.D. Rush Medical College, 1885; Hahnemann Medical College of the Pacific, San Francisco, 1892; three years surgeon to the State Penitentiary, Joliet, Ill.; died at his home in Wauconda, Ill., March 24, aged 63.

John Blaine Laidley, M.D. Long Island College Hospital, Brooklyn, 1883; of Conway, Mass.; manager of the local interurban railway; died in the Franklin County Hospital, Greenfield, Mass., March 18, from influenza, aged 51.

William Henry Harrison Sharp, M.D. University of Pennsylvania, 1868; Bellevue Hospital Medical College, 1870; a veteran of the Civil War; died at his home in Muhlenberg, Pa., January 6, from diabetes mellitus, aged 69.

David H. Reed (license, years of practice, Ohio, 1896); for fifty-five years a practitioner of North Fairfield, Ohio; for two terms a member of the state legislature; died at his home in that place, March 21, from pneumonia, aged 78.

Welton O'Bannon, M.D. Washington University, St. Louis, 1875; a member of the Missouri State Medical Association; mayor of New Madrid, Mo., for sixteen years; died in St. Louis, March 16, from nephritis, aged 56.

Eli Perry Rainwater, M.D. University of Louisville, 1891; (license, Tenn., examination, 1889); a member of the Tennessee State Medical Association; died at his home in Trion, March 26, from heart disease, aged 55.

Frank Worman Myrick, M.D. College of Physicians and Surgeons, New York City, 1899; a member of the Medical Society of the State of New York; died at his home in Binghamton, March 21, from pneumonia, aged 34.

Edward Sutton, M.D. College of Physicians and Surgeons, New York City, 1888; a member of the Medical Society of New Jersey; died at his home in German Valley, January 5, from cirrhosis of the liver, aged 43.

Walter John Smith, M.D. Yale University, New Haven, 1878; for three years an apothecary in the United States Navy; died at his home in Olneyville, Providence, March 13, from heart disease, aged 53.

George Fame Gaines, M.D. Louisville Medical College, 1877; of Madison, Ind.; died in the Central Indiana Hospital for the Insane, Indianapolis, February 21, from the effects of an overdose of morphin, aged 54.

Perry E. Tayer, M.D. Detroit College of Medicine, 1907; of Adrian, Mich.; a member of the Michigan State Medical Society; died in the Adrian Hospital, March 25, from pneumonia, aged 27.

Joseph Howard Mansur, M.D. Medical School of Maine, Brunswick, 1890; a member of the American Medical Association; died at his home on Orr's Island, Maine, Dec. 27, 1909, aged 44.

James Harvey O'Rear, M.D. Rush Medical College, 1873; at one time a member of the American Medical Association; died at his home in Medford, Okla., March 13, from chronic nephritis, aged 73.

William Moore Riddick, M.D. University of Pennsylvania, Philadelphia, 1856; a member of the Medical Society of the State of North Carolina; died at his home in Hartford, March 16, aged 79.

Thomas Benton Cable, M.D. Miami Medical College, Cincinnati, 1886; a member of the Ohio State Medical Association; died at his home in Pemberton, March 20, from nephritis, aged 53.

William S. Ruthrauff, M.D. University of Wooster, Cleveland, Ohio, 1876; formerly of Mountaindale, Pa.; died at his home in Coffeyville, Kan., March 22, from intestinal disease, aged 61.

William Hillswell Long, Jr., M.D. Jefferson Medical College, 1902; a member of the American Medical Association; died at his home in Philadelphia, March 25, from pneumonia, aged 48.

Alexander C. Sabin, M.D. Bennett Medical College, Chicago, 1882; formerly of Beatrice, Neb.; died at his home in Fairfield, Neb., March 20, from cerebral hemorrhage, aged 71.

Thomas Clay Nelson, M.D. New York Homeopathic Medical College, New York City, 1867; of Augusta, Ga.; a Confederate veteran; died at his home in Augusta, March 21, aged 66.

Susan Kendall Daggett Whitford, M.D. Bennett Medical College, Chicago, 1870; a pioneer woman practitioner of Elgin, Ill.; died at her winter home in Ozona, Fla., March 16, aged 73.

Petrus Nelson, M.D. Hahnemann Medical College, Chicago, 1872; said to have been the first specialist in ophthalmology in Minnesota; died at his home in St. Paul, March 21.

Isaac H. Dix, M.D. Cleveland University of Medicine and Surgery, 1869; of Pratt, Kan.; died at the home of his daughter in Salina, Kan., March 20, from influenza, aged 63.

Ralph Marcus Cole, M.D. Harvard Medical School, 1883; a member of the Massachusetts Medical Society; died at his home in Boston, March 12, from erysipelas, aged 50.

Henry Lisle, M.D. Medical College of Ohio, Cincinnati; who retired from practice in 1874; died at his home in Chetopa, Kan., March 1, from senile debility, aged 89.

Wesley Newell, M.D. McGill University, Montreal, 1884; Trinity Medical College, Toronto, 1887; died at his home in Sarnia, Ont., February 11, from nephritis.

Grafton W. Seaton, M.D. Louisville Medical College, 1870; a veteran of the Civil War; died at his home in Indianapolis, March 25, from heart disease, aged 63.

George Washington Matteson, M.D. University of Buffalo, 1855; died at his home in Middleville, Mich., February 24, from senile debility, aged 88.

Henry D. Rosenberger, M.D. Hahnemann Medical College, Philadelphia, 1875; died at his home in Manheim, Pa., March 17, from cerebral hemorrhage.

Elijah Zimmerlee, M.D. Fort Wayne (Ind.) College of Medicine, 1891; died at his home in Markle, Ind., March 28, from pernicious anemia, aged 67.

Charles Alfred Hudson, M.D. Rush Medical College, Chicago, 1871; died at his home in Kenton, Tenn., March 18, from catarrhal cystitis, aged 64.

Oscar Sneed, M.D. University of Tennessee, Nashville, 1881; died at his home in McKenzie, Tenn., March 21, from disease of the stomach, aged 69.

John A. Meadows, M.D. University of Nashville, Tenn., 1872; died at his home in Bethel, Tenn., March 22, from pneumonia, aged 65.

Herman Mitchell Sorin, M.D. Jefferson Medical College, 1902; died at his home in Camden, N. J., March 22, from pneumonia, aged 30.

Louis Drucklieb, M.D. College of Physicians and Surgeons, New York City, 1886; died at his home in New York City, March 23, aged 54.

James Shadwick Spiller, M.D. University of Maryland, Baltimore, 1870; died at his home in King William, Va., March 12, aged 61.

Thomas J. Poole, M.D. Southern Medical College, Atlanta, Ga., 1898; died at his home in Jakin, Ga., from typhoid fever, aged 38.

James M. Watkins, M.D. Rush Medical College, Chicago, 1864; died at his home in Green Valley, Ill., March 22, aged 79.

Wallace Steward, M.D. Eclectic Medical Institute, Cincinnati, 1872; died at his home in East Clarendon, Vt., March 20.

William R. Pearce, M.D. University of Nashville, Tenn., 1876; died at his home in Como Depot, March 25.

Book Notices

NUTRITION AND DIETETICS. A Manual for Students of Medicine, for Trained Nurses, and for Dietitians in Hospitals and other Institutions. By Winfield S. Hall, M.D., Professor of Physiology, Northwestern University Medical School. Cloth. Price, $2. Pp. 315, with Illustrations. New York: D. Appleton & Co., 1910.

In the present-day tendency to reduce the treatment of disease to rational and more nearly physiologic forms, the question of diet of course assumes an important rôle. Practical works covering the whole field of nutrition and dietetics are not numerous. With this idea in view the present work has been prepared for the use of nurses, students and general practitioners. Though for the most part elementary in character, as it must necessarily be to meet the requirements of its purpose, yet it contains a mass of valuable information for the general practitioner who is sometimes not well posted in the matter of diet for his patients. The arrangement of the book is admirable. Part 1 describes foods and their different classes, their preservation and preparation. Part 2, on the use of foods in the body, without entering into the anatomy of the digestive tract, with which it assumes the reader is acquainted, enters pretty thoroughly into the physiology of digestion, absorption and assimilation of foods, and the getting rid of waste material, stating well the present views on these subjects. Parts 3 and 4 on diet in health and disease go into these matters in a practical way, treating of the measure of fuel values, the relation of fuel values to diet, giving average requirements under different conditions, and constructing daily menus for the child, the adolescent, the athlete, the person of sedentary occupation, etc. The chapters on infant feeding under normal and abnormal conditions by Dr. Brennemann are complete and practical and would add value to any work on pediatrics. The suggestions as to diet in the infectious diseases and diseases of the digestive and other systems are valuable, though the directions for feeding in the febrile stage of typhoid fever are not very definite or complete; but more attention is given to the feeding during convalescence, and full directions are given for feeding tuberculous patients. The book contains two appendices. One gives a classification of diets, the object of which is not apparent, and also a collection of recipes for preparing articles not usually given in the household cook book, which is of greater value. The other appendix, giving experimental tests in the chemistry of foodstuffs and in the experimental chemistry of digestion, is so brief that its value perhaps is not great. The book on the whole, is a valuable practical addition to the subject of nutrition and dietetics and will fill a distinct place in the physician's library.

GULICK HYGIENE SERIES. Book One: GOOD HEALTH. By Frances Gulick Jewett. Cloth. Price, 40 cents. Pp. 172, with illustrations. Book Two: EMERGENCIES. By Charlotte Vetter Gulick. Cloth. Price, 40 cents. Pp. 173, with illustrations. Book Three: TOWN AND CITY. By Frances Gulick Jewett. Cloth. Price, 50 cents. Pp. 271, with illustrations. Book Four: THE BODY AT WORK. By Frances Gulick Jewett. Cloth. Price, 50 cents. Pp. 247, with illustrations. Book Five: CONTROL OF BODY AND MIND. By Frances Gulick Jewett. Cloth. Price, 50 cents. Pp. 269, with illustrations. Boston: Ginn & Co., 1910.

This is a series of five text-books, for elementary school use, on physiology and hygiene of body and mind. The contents of each are indicated by the titles given above. The various volumes are graded in the matter to adapt them to the intelligence of the pupils, beginning with those of the fourth grade. *A narrative style is adopted and the matter is presented in* such a way as to hold the interest of the pupil. The object kept in view throughout the series is to aid in the establishment of hygienic habits in the young and to inculcate the avoidance of everything inimical to the health of body and mind of the individual. Facts are given on which assertions rest, particularly as they relate to the pupil's own life and environment. Many examples and accounts of the work of physiologists are given in investigating various questions, such as the effects of alcohol, tobacco, work, play, sleep, bad air, etc. The plan of the series is original and the information is obtained from authoritative sources. Examples are given of actual work done in sanitation, etc., in various cities, and the work is freely illustrated. While some criticism might be offered that the volume on "Emergencies" goes a little too far into the medical treatment of too many things, and that the

Ella Louisa Dexter, M.D. Woman's Medical College of Pennsylvania, 1881; a member of the Massachusetts Medical Society; the New England Ophthalmological Society; New England Hospital Medical Society; ophthalmologist to the New England Hospital for Women and Children, Boston, and to the Pope Dispensary; died at her home in Chestnut Hill, Boston, February 3, from rheumatic arthritis, aged 52.

Francis W. Patterson, M.D. Medical College of Ohio, Cincinnati, 1859; University of Maryland, Baltimore, 1889; a member of the Medical and Chirurgical Faculty of Maryland; and a surgeon in the Confederate service during the Civil War; for a time United States Inspector of contagious diseases of animals; died at his home in Catonsville, Baltimore, March 22, from senile debility, aged 74.

Alfred Nelson Beach, M.D. Bellevue Hospital Medical College, 1870; of Cooperstown, N. Y.; for several years surgeon on steamships running between San Francisco and China; at one time a member of the general assembly of New York, and for two years police surgeon of New York City; died in Thanksgiving Hospital, Cooperstown, N. Y., March 10, from general breakdown, aged 61.

Henry J. Beyerle, M.D. Philadelphia College of Medicine and Surgery, 1851; in 1862 a member of the Indiana legislature; for 45 years a resident of Goshen, Ind.; for more than 30 years editor and proprietor of the *Goshen Times;* for 4 years a member of the city council and for two terms a member of the school board; died at his home, March 24, from senile debility, aged 86.

James Mitchell Blackford, M.D. Starling Medical College, Columbus, Ohio, 1865; a member of the Ohio State Medical Association; mayor of Martins Ferry, Ohio, in 1906; a member of the local school board for nine years; charter member of the Martins Ferry Hospital Association, and a director of the institution; died at his home, March 26, from senile debility, aged 72.

George M. Bazemore, M.D. University of Nashville, Tenn., 1861; Bellevue Hospital Medical College, 1874; a member of the Tennessee State Medical Association; for many years local surgeon at Cleveland for the Southern Railway; chairman of the Cleveland Board of Health; died at his home, March 24, from heart disease, aged 76.

Jefferson L. Thorpe, M.D. Washington University, St. Louis, 1886; a member of the American Medical Association; local surgeon at Jefferson City for the Missouri Pacific, Missouri, Kansas and Texas, and Chicago and Alton railroads; a member of the Cole County Board of Health; died at his home, March 22, from uremia, aged 47.

Gardner Perry Pond, M.D. University of California, San Francisco, 1893; a specialist on diseases of the eye, ear, nose and throat of San Francisco for several years, and later a resident of Los Angeles county; formerly a member of the American Medical Association; died at his home in Pasadena, March 19, aged 41.

Hector H. Goodman, M.D. University of Maryland, 1881; for three years surgeon to the Baltimore Police Department; and for 25 years medical director of the Baltimore Life Insurance Company; died in the Hebrew Hospital in that city, March 20, from cerebral meningitis, following an operation on the nose, aged 60.

George M. Bell, M.D. University of Michigan, Ann Arbor, 1870; Chicago Medical College, 1871; Bellevue Hospital Medical College, 1875; for more than 40 years a practitioner of Benton Harbor, Mich.; died March 27, at the University Hospital, Chicago, from cancer of the spleen, aged 61.

Henry A. C. Poppenhusen, M.D. University of Pennsylvania, Philadelphia, 1894; formerly city physician of Washington, Mo., and coroner of Franklin county; died at his home in Hermann, March 14, from the effects of carbolic acid, believed to have been taken with suicidal intent, aged 41.

George W. Carroll, M.D. Kentucky School of Medicine, Louisville, 1868; of Smithsonia, Ala.; a member of the Medical Association of the State of Alabama and a Confederate veteran; fell from a train near Barton, Ala., March 26, and died from his injuries a short time later, aged 70.

Roland C. Irving, M.D. Bellevue Hospital Medical College, 1877; a member of the Broome County Medical Society and Binghamton Academy of Medicine; first lieutenant and assistant [illegible], First Infantry, N. G., N. Y.; died at the home of a fri[illegible]n, March 17, aged 50.

Elisha Fenn, M.D. Bellevue Hospital Medical College, 1887; a member of the Medical Society of the County of New York City; a member of the Medical Society of the State of New York; for several years a member of the Seventh Regiment; died in Roosevelt Hospital, New York City, March 26, from pneumonia, aged 57.

Thomas J. Norris, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1874; a member of the American Medical Association, and organizer of the first medical society in Macon county, Mo.; a Confederate veteran; died at his home in Macon, March 23, aged 72.

Albert V. Ellershaw, M.D. Jefferson Medical College, 1891; a member of the Medical Society of the State of Pennsylvania; and formerly a practitioner of Norristown and Bridgeport, Pa.; died at the home of his father in Blackpool, England, recently.

Leslie Teasdale Pease, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1878; a member of the Illinois State Medical Society; a member of the council of Cisco; and a member of the school board for many years; died at his home, March 15, aged 57.

Harry Ellis Clemson, M.D. University of Maryland, Baltimore, 1894; a member of the American Medical Association; medical director of the Silver Cross Home for Epileptics, Port Deposit, Md.; died at his home, March 21, from heart disease, aged 37.

William Wallace Cole, M.D. Jefferson Medical College, 1869; a member of the Medical Society of the State of Pennsylvania; a veteran of the Civil War; assistant city physician of Pittsburg; died at his home, March 25, from heart disease, aged 67.

Samuel Jay Holliday, M.D. Northwestern Medical College, St. Joseph, Mo., 1882; a member of the American Medical Association; formerly of Pollock, Mo.; died at his home in Pennville, Mo., March 2, from lobar pneumonia, aged 53.

Joseph Dawson, M.D. Rush Medical College, 1885; Hahnemann Medical College of the Pacific, San Francisco, 1892; three years surgeon to the State Penitentiary, Joliet, Ill.; died at his home in Wauconda, Ill., March 24, aged 63.

John Blaine Laidley, M.D. Long Island College Hospital, Brooklyn, 1883; of Conway, Mass.; manager of the local interurban railway; died in the Franklin County Hospital, Greenfield, Mass., March 18, from influenza, aged 51.

William Henry Harrison Sharp, M.D. University of Pennsylvania, 1868; Bellevue Hospital Medical College, 1870; a veteran of the Civil War; died at his home in Muhlenberg, Pa., January 6, from diabetes mellitus, aged 69.

David H. Reed (license, years of practice, Ohio, 1896); for fifty-five years a practitioner of North Fairfield, Ohio; for two terms a member of the state legislature; died at his home in that place, March 21, from pneumonia, aged 78.

Welton O'Bannon, M.D. Washington University, St. Louis, 1875; a member of the Missouri State Medical Association; mayor of New Madrid, Mo., for sixteen years; died in St. Louis, March 16, from nephritis, aged 56.

Eli Perry Rainwater, M.D. University of Louisville, 1891; (license, Tenn., examination, 1889); a member of the Tennessee State Medical Association; died at his home in Trion, March 26, from heart disease, aged 55.

Frank Worman Myrick, M.D. College of Physicians and Surgeons, New York City, 1899; a member of the Medical Society of the State of New York; died at his home in Binghamton, March 21, from pneumonia, aged 34.

Edward Sutton, M.D. College of Physicians and Surgeons, New York City, 1888; a member of the Medical Society of New Jersey; died at his home in German Valley, January 5, from cirrhosis of the liver, aged 43.

Walter John Smith, M.D. Yale University, New Haven, 1878; for three years an apothecary in the United States Navy; died at his home in Olneyville, Providence, March 13, from heart disease, aged 53.

George Fame Gaines, M.D. Louisville Medical College, 1877; of Madison, Ind.; died in the Central Indiana Hospital for the Insane, Indianapolis, February 21, from the effects of an overdose of morphin, aged 54.

Perry E. Tayer, M.D. Detroit College of Medicine, 1907; of Adrian, Mich.; a member of the Michigan State Medical Society; died in the Adrian Hospital, March 25, from pneumonia, aged 27.

Joseph Howard Mansur, M.D. Medical School of Maine, Brunswick, 1890; a member of the American Medical Association; died at his home on Orr's Island, Maine, Dec. 27, 1909, aged 44.

James Harvey O'Rear, M.D. Rush Medical College, 1873; at one time a member of the American Medical Association; died at his home in Medford, Okla., March 13, from chronic nephritis, aged 73.

is shown by the programs received from the various county societies which are full of interest and show a strong tendency toward better educational methods in our societies.

It was also decided that every means possible should be used to present the programs and announcements to members in an attractive form, preferably in the shape of a periodical, issued as often as the affairs of the society would demand. We now have a number of county medical society papers called variously, *Reporter*, *Bulletin*, *Notes*, and *News*, published weekly, monthly or quarterly. These are exchanged between the various counties of the state and have in a short time been of the greatest value imaginable in closing the gaps between the various county organizations. Every little editor of us is pounding away for dear life, endeavoring to have a society above the average, and to edit a sheet that will be at least as good as the other fellow's, and to have in it material that will make his readers "sit up and take notice."

These Pennsylvania county secretaries also resolved that they would be good and prompt business men in the conduct of their affairs and would do all in their power to make the life of the state secretary a little easier. Further realizing that they were the agents of the state society all through the year, they felt that it was rather odd that their services could be dispensed with at the time of the annual session, and so, in their last conference they endorsed a resolution to amend the ordinances and by-laws of the state society so as to make the county secretary a member of the House of Delegates by reason of his office, as the county president is now. This amendment will be voted on at the next session of the society at Pittsburg.

The members of this conference are a forceful set of men, who are determined to boom their local organizations and to secure better organization of the medical profession generally, so as to improve the many conditions that make practice difficult or unpleasant. Marked developments and numerous innovations may be expected from this class of men and their organization.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
Bowling Green, Kentucky

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Eighth Month—Fourth Weekly Meeting

The Council on Pharmacy and Chemistry of the American Medical Association

History: Reasons for the creation of the Council; the U. S. P., the pharmacist, the practitioner of medicine, the manufacturing pharmacist, the ethical proprietary preparation, the nostrum.

Organization of the Council: The personnel of the Council, the professional standing of the members, what they have done in this particular field of work.

Objects: An inquiry into the composition and status of preparations offered to physicians, which are not found in the U. S. P., or standard text-books. The annual, "New and Nonofficial Remedies."

Rules Governing the Admission of Articles: Requirements as to formula, purity of ingredients, chemical tests, methods of advertising, claims of manufacturer as to ingredients, therapeutic properties, etc., name of article, etc. Admission of an article not an approval of it. Physician must decide as to therapeutic claims. Classification of articles examined and admitted. Reasons for rejections.

Results of the Work of the Council to Date: What may the practitioner do to aid the Council in this work? How may the county society help in this work? The relations existing between the members of this society and the local druggists. The practitioner and the detail man. The testimonial writer.

Publications of the A. M. A.: "New and Nonofficial Remedies," "The Pharmacopeia and the Physician," "Physicians' Manual of the U. S. P. and the National Formulary," "The Propaganda for Reform in Proprietary Medicine," various pamphlets.

Monthly Meeting

The Reasons for a More Exact Knowledge of Pharmacology on the Part of the Practitioner of Medicine.

The Difference Between the Ethical Proprietary and the Nostrum.

What the Practitioner and the County Society May Do to Aid the Council on Pharmacy and Chemistry.

Medicolegal

Sufficiency and Construction of Statute Authorizing Board to Revoke Licenses

The Supreme Court of Minnesota says that the complaint of the plaintiff in the case of Wolf vs. State Board of Medical Examiners (123 N. W. R. 1074) set forth that the board had caused a notice to be served on him to appear before it at a time and place stated and show cause why he should not have his license to practice medicine revoked. The ground stated in the notice was that he had been guilty of unprofessional conduct in that at divers times he had entered into business relations with a certain medical institute and had aided and abetted it in carrying on a questionable medical practice. The board, it was alleged, had not the capacity, qualification, or power to properly examine, pass on, or ascertain the facts as to whether the plaintiff had been guilty of immoral, dishonorable, or unprofessional conduct, or to summon, administer oaths, or compel the production of documentary evidence; "the ethics of the medical profession are vague and shadowy; there are a variety of medical schools represented on said board, all differing in their theory of ethics as well as on their medical theories; . . . they do not act under oath, and their action is wholly unrestrained, either by judgment, law, or conscience;" the board had fully determined in advance to revoke the license of the plaintiff without regard to the facts.

Section 2296 of the Revised Laws of Minnesota of 1905 provides in part that "the board may refuse to grant a license to, or may revoke the license of, any person guilty of immoral, dishonorable, or unprofessional conduct, but subject to the right of the applicant to appeal to the governor." It is obvious that this section is incomplete in itself. It is equally certain that the section must be construed together with other sections of the Revised Laws and general principles of law which are applicable. It is not true, as the complaint set forth, that the board is not required to take oath. The subscription of an oath is expressly required by section 2677. It is true that no notice nor form of notice is prescribed by section 2296. The gist of the power to revoke necessarily implies, however, the ability on the part of the board to prescribe legal forms. This section does not expressly confer on the board power of administering an oath. The deficiency, however, is fully supplied by section 2682. The nature and necessary construction of that statute confers that power. It is immaterial that its exercise is limited to questions of fact. No witness could properly swear to matters of law. While it is true that this section provides that such a board "shall have the power to administer such oaths as they may deem necessary to the proper discharge of their duties," it does *not provide* that they must. It was objected that the administration of an oath is therefore discretionary. If an instance were presented in which, as a matter of fact, the conclusion of the board rested on unsworn testimony, the question involved in that argument would be presented. No such state of facts was before the court in this case. The objection that the board has not the power to compel the production of documentary evidence is equally untenable. Section 4655 expressly confers the authority.

Objection was made to the form of notice served on the plaintiff by the board. That notice recited that it had been made to appear to said board that he had been guilty of unprofessional conduct. This he said demonstrated the prejudgement by the board of the merits of the case. Of this notice the trial court said: "From a lawyer's standpoint, the language employed (in the notice) might be improved, but it is simply a citation to answer before the board certain charges touching the professional and possibly the moral conduct of the plaintiff." This the supreme court thinks was the logical and proper construction. The notice was infelicitous, but not legally ineffective.

The constitutionality of the statute was attacked. This proceeding was commenced under the statute as it existed prior to the amendment thereof by chapter 474 of the General Laws of 1909; but it is clear that subsequent proceedings must conform to the statute as thus amended. The principal objection to the old statute was that it failed to provide a physician proceeded against for removal with an opportunity to review a possible removal before some tribunal authorized to hear and protect his rights, and hence deprived him of his liberty and property without due process of law. The new statute expressly provides for an appeal to the district court of the proper county on questions of law and fact, and thus answers every requirement of due process of law. It was intended to obviate the constitutional objection of the old statute. As it will govern further proceedings herein, it is unnecessary to determine the validity of the old statute. It is to be noted that the definition of the offense against professional propriety is in no wise altered. The change is one of procedure alone, and secures to the person proceeded against all his constitutional rights. The ability of the legislature to effect such change is beyond question. If the plaintiff should be removed, he would then have the right to review all proper questions on appeal. No adequate reason appears for granting him an injunction enjoining the board from proceeding further in the matter.

Physician Administering Anesthetic Not Liable from Not Protesting Against Operation Not Favored

The Supreme Court of Vermont says that the case of Lawson vs. Crane & Hall (74 Atl. R. 641) purported to be against the defendants as surgeons for not properly setting and caring for the plaintiff's broken leg. It appeared that at the plaintiff's house, some time after his injury, a Dr. Warren, assisted by a Dr. Burbank, broke over and set the plantiff's leg; Dr. Crane administering the anesthetic, but taking no other part in the operation. The plaintiff, in the opening of his case, called Dr. Crane as a witness, and asked him if he did not consider Dr. Warren's operation proper, and he said that he did not as it was performed, and in the place it was performed. He was en asked whether he made any objection to it or protest gainst it in the time of it, and he said that he did not. To this the defendants excepted, and the court holds that it was error, under the circumstances of the case, to admit the testimony objected to.

It appeared that a few days before that operation, the court goes on to say, that the defendants and Dr. Warren, who had been called for the purpose, met at the plaintiff's house and conferred as to whether anything or what further should be done to his leg. Dr. Crane advised that it be put into a plaster cast for a while, and then, if any further operation was to be performed, that the plaintiff be taken to some hospital where he could have expert care and attention. But it was finally determined at that conference to cut into the leg, break over the bone, and wire the parts together; and it was arranged that Dr. Warren should perform the operation, Dr. Crane consenting to administer the anesthetic, and in a few days the operation was performed accordingly, as before stated. Dr. Warren had exclusive charge of the case at the time of this operation, and directed everything done, and the charge of the case was with him ever after. There was no evidence tending to show that Dr. Crane was ever employed to have general charge of the case, but all the evidence tended to show that his employment was confined to the several occasions when he was called to assist.

Under such circumstances, it was error to admit the testimony objected to. Dr. Crane had already advised against any operation at the time and in the place it was performed; but his advice had been disregarded, and the operation was being performed contrary thereto, and was not subject to his control. Therefore he was not called on to object to, nor to protest against it, and hence no inference of approval of it could be drawn against him from his silence in that respect.

The plaintiff obtained a judgment in the lower court, but that is reversed and his petition dismissed, with costs.

1. **Serotherapy of Cerebrospinal Meningitis.**—Fischer reports a case of meningitis in an infant two months old, in which the diagnosis was made by tapping the lateral ventricle, and calls attention to the fact that the intraventricular method of injection has not proved successful in cases previously reported. The disease had commenced with vomiting, anorexia and gastric discomfort. These symptoms were relieved by a laxative, but two days later the mother noticed twitching of the arms, stiffening of the neck muscles, rolling of the eyeball, restlessness and insomnia, and at times a sudden piercing cry as though the child were in pain. On the following day the child was admitted to the hospital and the diagnosis not being positive, expectant treatment was carried out for a few days. Lumbar puncture was done and 1 c.c. of turbid blood-tinged fluid was withdrawn. The fluid was examined microscopically for meningococci with negative results. Three other lumbar punctures resulted in dry taps, and as the symptoms of rigidity opisthotonos, fever, and twitching were marked it was decided to tap the lateral ventricles. Fifteen c.c. of turbid fluid containing pus were withdrawn from the right ventricle, smears from which showed intracellular Gram-negative cocci. The ventricles were then irrigated with normal saline solution at 105 F. The excess of fluid was allowed to drain out through the needle and 2.5 c.c. of serum were injected slowly into the ventricles. During the injection of serum the infant's color changed from a waxy pallor to a uniform red flush all over the body. One-half hour after the injection the infant remained flushed, perspired profusely, and frothed slightly at the mouth; otherwise the condition was good. The next day the ventricles were again irrigated with 40 c.c. of saline solution and 20 c.c. of serum injected. On the next day the general condition was poor, opisthotonos was marked, arms rigidly extended, and palms everted outward. Occasionally the child flexed the arms and legs at elbows and knees. It lay quietly although not asleep; when a strong light was held in front of the face the dilated pupils contracted. Perspiration was free. Even a light touch with a pencil caused a spasm of muscular contractions involving all the limbs, and later these contractions occurred every few minutes without outward irritation. The pulse was 140, but regular and of good tension. On the next day lumbar puncture in the fourth interspace resulted in dry tap. A second needle was then inserted in the third interspace, and 15 c.c. of serum were injected, about 3 c.c. of which returned through the first needle. Then 15 c.c. were injected through the first needle, 5 c.c. of which returned through the second; in all, the infant retained from 20 to 25 c.c. of serum. Better results on the whole were obtained from the intraventricular injections. Two days later, 15 c.c. were injected into the ventricles, although no ventricular fluid could be withdrawn. The infant gradually improved during the next month, and was discharged 2½ months after admittance in normal condition. The eyes were examined by two ophthalmologists and both reports showed no evidence of blindness, nor is there evidence of deafness. Throughout its illness the child was breast-fed.

2. **Leprosy.**—Gottheil reports cases to prove the correctness of the assertions that under the conditions here prevalent at least, the lepra infection, while intractable and progressive, is very feeble; that with ordinary non-ulcerative cases, at least

the danger to others is very small; that many of the patients can pass along for years of practically good health and capacity for work after they are infected; and that leprosy is probably not hereditary, though, of course, the children living with leprous parents are especially exposed to the contagion. In advanced cases, of course, the patients belong in the hospital; in milder ones a home which the patients could voluntarily seek should be provided; but to practically incarcerate patients in the early stages and make a public charge of them is required neither for the protection of the community nor by the patients' needs.

8. **Origin of Papillitis.**—This theory, first propounded by Schieck, is based on the pathologic and anatomic examination of fresh bases of papillitis in which the posterior bulb section including the opticus was examined through serial cuts or sections, thereby showing that the inflammatory theory (Leber-Deutschmann) cannot possibly be right. All fresh specimens showed signs of edema at the distal end of the optic nerve, but not the least evidence of an inflammation either in the optic nerve iself or in its sheaths. Neither can the Schmidtman lymph space theory solve the causation of choked disc, because the fluid in the vaginal space was found to be of too small amount to cause pressure on the nerve and strangulation of the blood vessels. Much less credibility has Deyl's theory of the compression of the central vein within the intervaginal space. And also that of Knapp with regard to compression of the vein in its course through the edematous dural sheath, since at both points the vein was found wide open. On the other hand, a very noticeable widening of the perivascular lymph channels in the axial strand was found in every case.

9. **Operation for Correction of Hammer-Toe.**—After the usual preparation of the foot for operation and after the Esmarch bandage has been applied, a skin incision, one and one-quarter inches long, is made at the outer aspect of the plantar surface of the toe, the center of which incision is at the flexed joint. The skin flaps are dissected laterally, sufficiently to expose the underlying structures. The incision is continued through the subcutaneous structures, being careful to expose the digital branch of the artery and the nerve and to prevent their injury while continuing the dissection down to the joint. The sheath containing the flexor tendons is then dissected free from the joint and held aside sufficiently to allow of the removal of the articulating joint surfaces with the chisel, observing due care to have sufficient flat surface at right angles to the shafts of the contiguous bones as a result of the arthrodesis. No bone suture is necessary. The subcutaneous structures are then allowed to fall back in place and are held by a few fine buried catgut sutures. The skin is closed with interrupted chromic gut and dressings applied. A plaster of Paris bandage, fixing the toes in hyperextension, making the flexor tendons tense, thus holding the bony surfaces of the phalanges operated on in close apposition and in straight line, is finally applied. After ten days, the plaster of Paris is split and the dressings are removed sufficiently to expose the field of operation. Then the dressings are restored and maintained in the original position for six weeks. The patient is allowed up on crutches after the first dressing.

Boston Medical and Surgical Journal

10 *The Present Status of Vaccine Therapy. W. Tileston, New Haven.
11 Local Anesthesia (Neumann) in Ear Surgery. J. J. Hurley, Boston.
12 *Tuberculosis of the Shoulder in Children. J. W. Sever, Boston.
13 The Hospital Dietitian. W. F. Boos, Boston.

10. **Present Status of Vaccine Therapy.**—According to Tileston in certain localized infections, particularly those due to the staphylococcus and tubercle bacillus, vaccine therapy has clearly proved its worth and stands on firm ground. In the general infections it has not so far shown results which are distinctly better than those with other forms of treatment.

12. **Tuberculosis of Shoulder in Children.**—In Sever's series there were 11 children who developed abscesses which required operations. There were 8 who needed one operation, 5 who had two, 1 who had three, and in 5 cases resection, partial or complete, was necessary of the head of the humerus. As is natural in these cases which required frequent operations, there was the greatest amount of bone destruction and they generally required excision of the head of the bone. The results are not encouraging, even with the best treatment. An ankylosed joint is usually the ultimate result. When the case involves much bone and cartilage, ankylosis always occurs, but when the type is synovial there may be some motion. Eleven cases showed no motion in the joint. In four of these there had been resection of the head of the humerus, 1 child had a moderate amount of motion following resection, and 6 who had not had resection showed motion varying from a very slight amount to about one-half normal.

30 *The Balsam-Oil Dressing in Surgery. A. L. Parsons, Louisville.
31 Woman as a Life-Insurance Risk. H. J. Farbach and J. G. Cecil, Louisville.
32 Indicanuria. F. C. Askenstedt, Louisville.

30. **Balsam-Oil Dressing in Surgery.**—The advantages of the balsam-oil dressing are stated by Parsons to be as follows: (1) There is continuous drainage of the wound surface; (2) wound secretions are not retained under an impervious scab, and the absorption of toxins is thus avoided; (3) bacteria are killed and eliminated from the field; (4) epithelium grows and is not rudely torn off at each dressing; (5) dressings are almost painless; (6) granulations are encouraged but do not become spongy; (7) irrigation is unnecessary; and (8) the wound does not require redressing oftener than at intervals of from 48 to 72 hours.

38. **Effect of Pregnancy on Laryngeal Tuberculosis.**—Laryngeal tuberculosis whether present at the time or developing during gestation, is increased very much during pregnancy. This development of the disease renders suffocation imminent, from the edema which often accompanies it. Tracheotomy is the only means for relieving the suffocation, and as it cannot always be done in time to save life, this fact has led to the acceptance of laryngeal tuberculosis as a positive *indication* for the artificial interruption of pregnancy.

43 A Case of Diphtheria. C. S. Webb, Bowling Green.

40. **Invagination of Small Intestine Into Colon.**—On opening the abdomen in a case of intussusception, Kelly found that the small intestine had inserted itself into the colon from the ileocecal valve to within an inch and a half of the anus. This was pulled out, but the part above the cecum was so necrosed and gangrenous that the head of the cecum and about four inches of the ileum had to be resected. This was done very quickly the child being removed from the table in as good condition as when he was placed there. His bowels moved soon after he had reached the bed. In spite of stimulation, he died the same night. The point of chief interest in the case is that the patient lived seven days after the intussusception occurred, and also to note with what ease an operation might have been done had the diagnosis been made earlier.

52. **Intramural Abscess in the Puerperal Uterus.**—The reported authentic cases of intramural abscess of the puerperal uterus, according to Sampson, are few in number, probably not over 25, and, as many of them are briefly described, he does not feel warranted in drawing definite conclusions concerning the various phases of the subject. Nevertheless a general summary is not out of place. There are two distinct groups of cases: 1. Those in which the uterine abscess or abscesses are the only results of the puerperal infection present in the case, or if not, they are the most important ones and the principal cause of the patient's illness, as in the first two cases reported. The condition in this group exists as a distinct clinical entity. 2. Those in which the uterine condition is secondary in pathologic importance to others which may result from puerperal infection. There may be multiple abscesses in the organs and structures of the pelvis including the uterus, or the abscesses in the uterus may be overshadowed by some such condition as purulent peritonitis or thrombophlebitis, as in the last two cases reported. The uterine condition in this group loses its entity on account of the greater importance of the other conditions present. These cases are very rare, and are one of the results of puerperal infection. The number, size and distribution of these abscesses resemble closely those of uterine myomata. The patient gives a history of puerperal infection following labor or abortion, which has not cleared up, *i. e.*, has become chronic. The subjective symptoms may be slight. On the other hand, the general symptoms of infection and the local ones of pelvic inflammation may be severe. The general signs of infection are present; they vary in severity, but may be of a low grade. Diagnosis is not always possible, and it must be by exclusion. The following possible terminations of this condition present themselves and all have clinical confirmation: (1) rupture into the uterine cavity; (2) rupture into the peritoneal cavity; (3) extension into the retroperitoneal tissues; (4) rupture into the intestine; (5) rupture into the bladder; and (6) rupture of a cervical abscess into the vagina. The condition should be treated by surgical interference.

57. **Chloroform in Treatment of Eclampsia.**—The usual plan at the Sloane Maternity, New York, is to deliver as soon as possible, consistent with the mother's soft parts, after the occurrence of the first convulsion, if not before. If the cervix is soft and dilatable, an immediate *accouchement forcé* is done. If the surface is rigid and undilatable, preliminary softening by the Voorhees bag is used, the patient meanwhile being put on active anti-eclampsia treatment. There are here one or two periods when an anesthetic is required, and until last year chloroform was invariably used at the Sloane Maternity. The amount of the drug used varied with the individual case. For the introduction of the bag little is necessary, but the average patient is not easily controlled, her apparent strength is remarkable, and in some cases at least considerable chloroform is likely to be used. The records show that the average duration of the anesthesia for each of 15 patients was 43 minutes, even including in the average, several post-partum cases in which, with normal deliveries, but from one to five minims of chloroform was used for the control of the head and delivery over the perineum. To one patient chloroform was administered for 120 minutes, to another for 107, to another for 68, and so on. The charts also show that the patients who were in the worst condition on admission were those who required the longest anesthesia. Naturally these patients did not all receive chloroform to the surgical degree throughout the entire time, obstetrical anesthesia being all that was desired for at least a part of the time, but even so, it is evident that the anesthesia was prolonged and the amount of the drug used considerable. A further use of chloroform, as commonly used in the treatment of eclampsia, is for the control of the convulsions. Since March 15, 1909, there have been at the Sloane Maternity 12 cases of eclampsia in a series of 1,261 confinements. Any patient showing any symptoms of a toxemia, no matter how slight, has been treated without chloroform. Ward feels that by this method they have undoubtedly cut down the number of patients showing actual convulsions, *i. e.*, eclampsia. In these 1,261 women Ward has used no chloroform whatever in toxemic or eclamptic cases except in two patients early in the series. Neither of these patients was very toxic, as these cases go, and only small amounts were used for delivery. There have been no maternal deaths. A small series such as this means little, and similar results have been obtained under the chloroform treatment in a larger series of cases. Ether has been used for actual delivery or for any manipulations when an anesthetic has been required. These patients take ether as well as chloroform, and there is no difficulty in its use. Aside from the control of the convulsions, Ward uses the regular accepted treatment of the condition—emptying of the uterus as soon as consistent with the mothers' soft parts; veratrum viride, chloral, nitroglycerin, hot packs or hot-air baths, colon irrigations, forced fluids, etc. Looking at the convulsions as purely a symptom he makes no effort to control them on their own account, except as they are controlled by the general treatment which is designed partly to keep them in check, and at the same time, to stimulate as much as possible the eliminations.

58. **Latero-Lateral Anastomosis of the Ileum.**—All the cases observed by Noble on which this report is based were bad ones, and the patients were willing to submit to anything

holding out the least encouragement. With few exceptions, they were poorly nourished, anemic, neurasthenic subjects, often suffering from atonic dilatation of stomach, achylia, pyloric insufficiency, enteroptosis, and various pelvic lesions. They were in a state of invalidism, some having been confined to bed for from a few months to as long as two years, and were selected for the operation because they had been subjected to thorough trials of medical treatment and diet without material mitigation of symptoms.

Of the total number, 27, 18 now have evacuations of bowels from one to three times daily without laxatives. Of the remaining 9, 3 take laxatives, 2 use injections of either water or oil, 2 control motions by regulating their diet, of 1 no record has been received, and there is 1 other case too recent to record. About 75 per cent. of the patients are relieved of constipation sufficiently to avoid the use of medicines; 2 reported constipation; and 2 who acquired the habit of using injections before the operation have not allowed themselves an opportunity to see how the bowels will move without them. The relief of colicky pains has been remarkable; some individuals recovered in a few weeks and others gradually improved. Tenderness and soreness also disappeared after the effects of the operation cleared up. One of the most noticeable effects was the relief of gaseous distentions, some enormously distended abdomens, requiring anodynes to relieve pain almost daily, being promptly and effectually relieved by the operation. Only a few of the recent patients report any discomfort from this cause. Twelve patients pass no mucus at all, 10 very little, at times, 4 recent patients reported mucus much decreased, and 1 patient has not been heard from directly; 22 have been cured; 1 case is not reported. All have gained more or less in weight and strength. In 2 cases the appendix had previously been removed without affecting the colitis. In about half the remaining cases, appendectomy was done at the time of anastomosing intestines, but none of them showed any advantage or improvement over those in which the organ was left intact. The operation is based on the principle that mucous colitis is largely caused by constipation and putrefactive decomposition. The direct object of the anastomosis is to drain the most intensely infected section of the ileum, preventing its discharges into the cecum; for the amount of decomposition, irritation and absorption of toxins is in proportion to the quantity and character of material entering the colon. In the technic of the operation, the suture method is preferred, and the anastomosis is made as low down on the ileum and sigmoid as the two portions of the intestinal canal can be approximated without tension.

59. **Suppuration of a Uterine Fibroid.**—The point emphasized in this case by Schumann is that the constitutional disturbance and inflammatory reaction were due to a relatively minute focus of suppuration but one in which the pus was under high tension. A routine examination of the tumor and uterine appendages gave no hint of the cause of the disturbance, which was only made manifest by the opening of the small abscess cavity about the root of the polyp.

74. **Ionic Surgery in Cancer.**—Between 1893 and January, 1905, Massey employed ionic surgery in 14 cases of malignant growths within the mouth, 2 of which were operable in the ordinary sense and 12 inoperable, most of them hopelessly inoperable. Of these 4 patients were cured, including the 2 operable patients, and are well 5, 8, 9 and 12 years after treatment. Three died during or shortly after the operation, 2 were relieved for a long period of time, but finally relapsed, and 5 operations were failures to arrest the disease for any length of time.

88 *Experimental Epidemic Poliomyelitis in Monkeys. S. Flexner and P. A. Lewis, New York.

80. **Influence of Organs on the Catalytic Action of the Blood.**—The conclusion of Batelli and Stern that catalase is not found in a single tissue but is produced by various tissues which support each other in preserving high catalytic activity of the blood is verified. After destruction of the function of the thyroid the catalytic action of the blood declines and after destruction of the function of the kidneys the catalytic action of the blood and the tissues declines. The thyroid is intimately concerned in preserving the high activity of the blood and this is of interest because of the influence of this gland on physical and mental activity.

82. **Peritoneal Patching of the Aorta.**—Carrel found that by using a patch of peritoneum the aortic wall can regenerate itself so perfectly as to become absolutely normal, even though the new wall is composed of tissues different from the normal tissues of the aorta, yet the morphology was not greatly modified.

83. **Remote Results of the Replantation of the Kidney and Spleen.**—Carrel is now able to replant (in the same animal) the kidney or spleen on the renal or splenic vessels easily and safely. After the operation the animals remain generally in good health. Thus the left kidney of a dog was removed and perfused with Lockes' solution and replanted, the circulation being reestablished after an interruption of 50 minutes. Fifteen days afterward the right kidney was removed and the animal has remained in perfect health up to the time of this report, that is to say 23 months; hence the operation does not interfere with the function of the organs, at least within the time specified. In 4 other experiments three successful results were obtained. In one case the spleen disappeared. In the other 3 experiments the anatomic conditions of the replanted kidney or spleen were found entirely normal, when removed a long time after the operation. Several dogs, whose left kidneys were replaced some months by the left kidneys from other dogs are now living and in good health. Some time later it is proposed to endeavor to determine, if possible, the value of the transplantation of organs.

87. **Experimental Acute Nephritis.**—By the study of experimental nephritis with physiologic and anatomic methods, types in which either tubular or vascular changes predominate may be distinguished. Potassium chromate, uranium nitrate and corrosive sublimate cause extensive tubular injury without evidence of vascular injury, while arsenic and cantharadin produce but little injury to the tubules but cause

anuria. Physiologically, these two types represent tubular and vascular nephritis. In the tubular form the output of nitrogen is considerably diminished. In the vascular nephritis the nitrogen elimination is greatly increased.

88. **Experimental Epidemic Poliomyelitis.**—In this article Flexner and Lewis give a connected and detailed statement of their work on *experimental poliomyelitis in monkeys. Most* of the results obtained have been reported in a preliminary way from time to time in The Journal (1909, lii, 1639, 1913, 2095; 1910, liv, 45, 535). This study has yielded a large number of important facts bearing on the disease in man. The filterable character of the virus has been discovered and many of its properties have been ascertained. Some observations in regard to immunity have been made, as well as in regard to the clinical and pathologic peculiarities of the disease. A basis has been secured for the development of preventive measures.

100 **Analysis of the Principal Causes of the Infant Mortality of* Cleveland, 1908 and 1909. A. F. Furrer, Cleveland.

96. **The Traumatic Neuroses.**—Boone's observations covering nearly 17 years, have been in connection with the claim and legal departments of liability insurance companies, street and steam railroads, and in the cases in which traumatic nervous disorders furnished the basis of claims, he estimates that at least 95 per cent. *of the claimants fully recovered* within a reasonable time after their claims have been disposed of.

99. **Mercury in Pulmonary Tuberculosis.**—Placak's experience with the succinimid of mercury has been limited to about 20 cases, yet this number has been sufficient to convince him that *mercury will fall by the wayside as many so-called specifics in tuberculosis* have done in times gone by. Many of the patients after a length of time claimed they received no benefit and on account of the pain refused to take the injections.

100. **Infant Mortality of Cleveland.**—*The infant mortality* in Cleveland, according to Furrer, is approximately 25 per cent. of the total death-rate (1907, 1908, 1909). The so-called severe infectious diseases play such a small part in the causation of this mortality that they are comparatively unimportant, scarlet fever, whooping cough, diphtheria and tuberculosis, together causing but 50 deaths out of 1,800. Diarrhea and enteritis, convulsions and "early infancy," or in other words the gastrointestinal diseases, were directly or indirectly responsible for about 1,200 deaths, which represent two-thirds of our total infant mortality. Furrer urges that the present classification of diseases pertaining to *infants* as reported in city mortality statistics should be revised.

105. **Ammonia-Destroying Power of the Liver.**—Carlson and *Jacobson experimented on thyroidectomized* cats and foxes to determine the influence of removing the thyroid and parathyroids on the metabolism of ammonia by the liver cells. In animals treated in this way when symptoms of excitation and depression are exhibited, the blood contains more ammonia than that of normal animals and the livers show a marked depression in the ammonia-destroying power as compared to the liver of the *normal* animals. In animals which show no symptoms these changes do not appear. The increase in the ammonia content of the urine and blood *after complete* thyroidectomy, is due, at least in part, to liver depression rather than to acidosis *independent of the liver. The authors* suggest that the detoxication function of the parathyroid is *probably due to influence on the liver and other organs* rather than to neutralization processes *in* the glands themselves.

108. **Removal of Fragments of the Intestinal Tract.**—Carrel, Meyer and Levene continued their experiments to determine the functions of the different segments of the digestive tract by *removing the small intestine. They found that there was a diminution of the absorption of ingested proteins and of* leucin, but there seemed to be no disturbance of the power of assimilation and retention of the absorbed protein. They conclude, *therefore, that the stomach and not the intestines is the organ principally concerned in the function of protein* assimilation.

119. **Amber-Tinted Lenses for Asthenopia.**—The use of amber-tinted lenses *in ten cases, by Hilgartner,* has been satisfactory, with one exception, a case of extreme hysteria.

120. **Surgical Relief of Nephritis.**—Cantrell has faith in surgical effort for the relief of Bright's disease based on some little work. He mentions 19 patients, including a number who were operated on for floating kidney, and who presented tube casts and epithelium. He has lost only one of his patients and this loss occurred nearly two years after the *first* operation. In this case he was induced to make a second attempt, hoping that he might be able to relieve the distressing symptoms. The patient did not die immediately after the operation, but several weeks later. Cantrell's entire list of *living* patients is greatly improved. They are all well pleased with the effort, and while Cantrell cannot claim that any one of them is cured, he is convinced beyond a doubt that they are all greatly relieved, and this relief, he says, is well worth the effort which has been made.

March 12

1 *Causes and Treatment of Functional Dyspepsia. D. Drummond.
2 *Reflex Pain in Diseases of the Abdominal Viscera. A. E. Maylard.
3 How to Operate for Appendicitis. R. P. Rowlands.
4 *The Effect of Abdominal Compression in a Case of Very Rapid Heart. W. Gordon.
5 *A Red Line on the Gums. G. A. Stephens.
6 The Cerebellum and its Diseases. J. S. R. Russell.

1. **Causes and Treatment of Functional Dyspepsia.**—Drummond is so convinced of the practical importance of hunting out the inducing cause in each case of indigestion with a view to its removal, that he regards investigation of the secretory activity of the stomach, followed by prescription of appropriate diet or acid and antacid remedies, as being valuable, no doubt, for giving relief, but only too often insufficient for a cure. Foremost among perplexing and often highly elusive causes of gastric dyspepsia stand mental and nervous disturbances, he says. Practice among all classes of society furnishes many examples which belong to this group, and the fact will at once occur that one of the most useful of therapeutic measures in stomach cases is rest in bed.

2. **Reflex Pain in Disease of Abdominal Viscera.**—Without attempting to differentiate clinically between the lesions causing pain in the same spot, Maylard gives a sort of classified list of the diseases which may be expected to cause reflex pain in certain definite areas. Thus, (1) perforation of gastric or duodenal ulcer, rupture of gall-bladder and acute hemorrhagic pancreatitis cause acute pain to be felt in the epigastrium; (2) perforation of the appendix or of the small intestine, ruptures, strangulations and obstruction from various causes, embolism or thrombus of the mesenteric vessels, etc., cause acute pain to be felt in the region of the umbilicus; and (3) rupture in tubal affections including extrauterine pregnancy, causes acute pain to be felt in the hypogastrium. He emphasizes the fact that while diseases of the abdominal viscera may give rise to reflex pain located in one or other of the anatomic regions into which the abdomen is artificially divided all reflex pains experienced in these particular regions do not necessarily signify diseases of the abdominal viscera.

4. **Abdominal Compression in Tachycardia.**—Abdominal compression is a recognized method of treatment in paroxysmal tachycardia and in cases cited by Gordon it appeared to have been the chief means of saving life. April 3, a man, aged 68, was thrown down by a large motor car which backed on to him. A certain amount of general shock was sustained. The man was not neurotic. His pulse on the day of the accident was 100, and between April 3 and 10 it varied between 100 and 80. Two days after the accident he complained of severe abdominal pain and vomited three times. On April 9 he began to complain of an aching pain over the heart, with a good deal of flatulence and abdominal distention, and his pulse became rather weak, intermittent and irregular. The heart was apparently of normal size, free from murmur, but with rather feeble sounds. There was slight pulmonary emphysema, but no other lung trouble. The urine was normal. A mixture containing bismuth, a sodium salt, carbolic acid, and nux vomica was ordered and a simple aperient. The pulse was then very small, irregular and intermittent, running about 100, and the patient was pale and perspiring. There was no dyspnea, no distention of the veins in the neck, no sign of cardiac dilatation. There was no murmur or friction to be heard, only rather feeble sounds. He still complained of aching over the heart.

Under treatment the pulse improved somewhat, remaining, however, very intermittent. Next day it rose further in frequency, and at 2 p. m. was running at 144. On April 13, the right saphenous vein became thrombosed. The pulse was then counted at 180. Next morning it was counted at 74. Cheyne-Stokes breathing was very marked on April 14, and occurred occasionally for several days. From this time until April 21, a very serious condition was maintained, the rate of the pulse varying greatly from time to time, but being usually excessive, and often very rapid. At no time was there dyspnea, cardiac dilatation or murmurs, distention of veins or edema, except in the thrombosed leg. During full inspiration the feeble rapid pulse became absolutely obliterated. Gordon then decided to try the effect of abdominal compression, and a stout flannel binder was tightly applied over the entire abdomen at 11:40 a. m. No other change was made in the treatment. The pulse returned to an ordinary rate, 72. The effect of the binder, Gordon thinks, can best be explained by its effect on the overcharged splanchnic circulation.

5. **Red Line on Gums.**—The typical lead line, according to Stephens, is seen to be just under the surface of the edge of the gum, and situated in the papillæ, and under a magnifying glass presents an interrupted appearance. These papillæ in some cases become enlarged almost to the extent of rupture. About two years ago, when examining the men at a factory in his district where lead ore is handled, Stephens was particularly struck with the fact that a large percentage of their gums showed a distinctly red line. This red line is, in his opinion, due to an enlargement of the papillæ at the edge of the gum, and peculiarly enough, was seen in lads who had been only from 14 to 28 days at the works, as well as in the outside men, such as masons, whose contact with fumes occurred only when the latter were diluted. The conclusion that Stephens arrives at from such fact is that the so-called lead line is no proof of lead in the system, but that it appears in workers whose gums have been irritated by particles other than lead.

Lancet, London

13 *Treatment of Vomiting. J. Snowman.
14 Reform of Medical Poor-Law Relief. C. T. Parsons.
15 Maison Barlier. H. Mac-Naughton-Jones.

7. **Angina Pectoris.**—Osler has notes of 268 cases in all—231 men, 37 women. If we recognize a mild neurotic or pseudoneurotic, and a grave organic or true form, there were of the former 225, and of the latter, 43. Osler has not counted *les formes frustes* unless a patient had subsequent severe attacks. Of the severer form of 225 cases, there were only 14 women. On the other hand, of the minor type, of 43 cases there were 23 women. The age incidence is late, the largest number of cases occurring in persons over 50. Of the 612 deaths in England and Wales, only 36 occurred between the ages of 35 and 45; while between 45 and 65 there were 291 deaths. In Osler's list the age was much the same. There were under 30 years of age, 9; between 30 and 40, 41; between 40 and 50, 59; between 50 and 60, 81; between 60 and 70, 62; between 70 and 80, 13; and above 80, 3. In women the age incidence is, on the whole, a little lower than in men.

A point that stands out prominently in Osler's experience is the frequency of angina pectoris in physicians. Thirty-three of his patients were physicians, a larger number than all the other professions put together. Only 7 were above 60 years of age, one a man of 80, with aortic valve disease. The only comparatively young man in the list, 35, was seen nearly 20 years ago in an attack of the greatest severity. Worry and tobacco seem to have been the cause. He has had no attack now for years. Two cases were in the fourth decade, 13 in the fifth, and 11 in the sixth. Neither alcohol nor syphilis was a factor in any case; of the 26 patients under 60, 18 had pronounced arteriosclerosis, and 5 had valvular disease. In a group of 20 men, every one of whom Osler knew personally, the outstanding feature was the incessant treadmill of practice, and yet, every one of these men had an added factor, worry.

So far as symptoms are concerned, Osler's cases fall into three groups (1) *les formes frustes;* (2) mild; and (3) severe.

1. The mildest form "*les formes frustes*" of the French, with substernal tension, uneasiness, distress, rising gradually to positive pain, is a not infrequent complaint, one, indeed, from which few escape, is associated with three conditions. Emotion is the most common and the least serious cause.

2. Under the mild form, angina minor, come 43 cases. Osler has grouped under these, the neurotic, vasomotor and toxic forms, the varieties which we formerly spoke of as false or pseudoangina. The special features of this variety are: the greater frequency in women, the milder character of the attacks, and the hopeful outlook.

3. Severe angina, angina major, is represented by 225 cases, of which 211 were in men. Two special features here are, existence in a large proportion of all cases of organic change in the arteries and liability to sudden death.

9. Clinical Significance of Gastric Hypersecretion.—Hypersecretion of gastric juice, according to Fenwick, invariably depends on an organic lesion, which usually takes the form of a chronic ulcer of the stomach or duodenum, calculus in the gall-bladder, or latent disease of the appendix, although it is probable that future investigations will prove that pancreatic calculus, tubercle of the cecum, and carcinoma of the appendix are also capable of producing it. Of the last named, one case has already come under his observation. This disorder of secretion is merely the physiologic expression of a reflex irritation of the gastric glands, and is therefore not entitled to be regarded as a disease. The continuous flow of hyperacid gastric juice, whatever be its cause, always excites severe inflammation of the stomach, and is liable to be followed by ulceration of that viscus or the duodenum. This secondary ulceration is at first superficial in character and may not be demonstrable on examination of the exterior of the stomach. Minute hemorrhagic erosions capable of producing alarming hematemesis and melena are usually associated with and caused by this abnormality of the gastric secretion. Latent disease of the appendix as a result of former acute inflammation is accompanied by a peculiar form of digestive disturbance. In this condition, subacidity of the gastric juice with an absence of free hydrochloric acid is the rule.

With the exception of hemorrhage, all the symptoms that are regarded as pathognomonic of duodenal ulcer are in reality due to the gastric hypersecretion that always accompanies this lesion. It follows, therefore, that a severe example of hypersecretion may, as a rule, be safely diagnosed as a case of duodenal ulcer. Contrary to the usual belief, carcinoma of the pylorus is sometimes accompanied by extremely well-marked hypersecretion. In such cases the morbid growth develops with extreme rapidity and violent hemorrhages, due, possibly, to digestion of the tumor, are exceptionally frequent.

10. Appendicular Gastralgia.—Paterson holds that appendicular disease may give rise to symptoms which closely mimic the supposed symptoms of gastric and duodenal ulcer. The prominent symptom is epigastric pain or severe discomfort after food; in many cases there are sour eructations, vomiting, and even hematemesis and melena. The radiation of epigastric pain to the lower abdomen is suggestive of appendicular trouble. Gastric analysis reveals, in some cases, hyperchlorhydria, in others a normal amount of free hydrochloric acid, in others a marked diminution or absence of free hydrochloric acid. As a rule, there is an increase of the volatile acids, and in some cases evidence of hypersecretion. Some cases of hypersecretion or acid dyspepsia and many cases of supposed gastric or duodenal ulcer are due to latent appendicular disease.

The evidence that the gastric symptoms are due to appendicular disease is threefold: (a) the majority of patients are cured by appendectomy; (b) the influence which appendectomy has on the gastric contents; and (c) the frequency of a previous history of gastric symptoms in those who have an attack of acute appendicitis. The symptoms are probably the result of intestinal toxemia due to intestinal stasis. The effect of gastric secretion is, in the early stages, possibly due to pyloric spasm, but more probably to some influence of the appendix on gastric secretion. Appendicular gastralgia is apparently more common in women than in men.

The important lessons to be learned from these cases are as follows, Paterson states:

1. No operation should be performed on the stomach except when a definite organic lesion of the stomach or duodenum exists. Gastrojejunostomy will not cure appendicitis.
2. In all operations for supposed gastric or duodenal ulcer, the conditions of the appendix should be carefully investigated.

13. Treatment of Vomiting.—In the treatment of vomiting Snowman says that the first point to determine is whether it is an incidental symptom of an acute illness or a cardinal feature of some chronic disease. The ordinary therapeutic measures available for treatment of vomiting are numerous and somewhat conflicting in their variety, a testimony to the failure which so often attends their administration. Nausea may be relieved occasionally either by sips of extremely hot water or by sucking fragments of ice. This contrast is still further seen in the circumstance that sometimes a tight abdominal binder will stop nausea, whereas at other times this very unpleasant sensation yields when the clothing around the abdomen is loosened. Perfect recumbency in the horizontal position should be maintained, and such local applications to the epigastrium as sinapisms, blisters or leeches are frequently very useful. The washing out of the stomach with weak boric lotion or alkaline solutions is an excellent method of treating the persistent vomiting in gastric dilatation or the gastric catarrh of infants.

Snowman in discussing the treatment says that the favorite drug for vomiting is bismuth in one of its various forms. Cerium oxalate probably acts in the same way as bismuth but nothing definite is known of its pharmacology. It has acquired a reputation in the treatment of vomiting of pregnancy, but clinical experience generally fails to confirm it. Creosote, iodin and carbolic acid may be grouped together as a series of drugs which allay vomiting when suitably employed. Aconite has some vogue in the treatment of vomiting, but it must be given in large doses. Chloretone, he believes, is an effective remedy when some painful local disease such as cancer of the stomach, is responsible for the vomiting. One-third of a grain of cocain will occasionally put a stop to a bout of vomiting, and is one of the most effective remedies available for seasickness. Hydrocyanic acid is another drug with a reputation in gastric vomiting, but if it acts it does so forthwith, and if it proves to be unsuccessful at first it is merely a waste of time to persist with it. Opium, he declares, is the most valuable remedy for vomiting which is persistent and exhausting, and then it must be given in the form of a hypodermic injection of morphin.

27. A similar article by the same authors was abstracted in THE JOURNAL, Feb. 5, 1910, page 500.

28. **Arterial Pressure and the Suprarenal Glands in the Tuberculous.**—Sézary has been examining the condition of the suprarenals in tuberculous patients whose arterial tension had been systematically recorded during life. His findings fail to sustain the assumption that the lower blood pressure is always the result of lesions in the suprarenals. The low tension at first is probably due to the diffusible toxins of the tubercle bacilli; and it is not until later that the suprarenals become incompetent. In three cases he found a relatively high blood pressure, although autopsy showed complete destruction of the suprarenals. A concomitant nephritis in all these cases was probably responsible for the high arterial tension, but the tension was lower in these patients than in the non-tuberculous who had the same kind of kidney lesions, and there was thus relative hypotension.

29. **Induction of Vomiting in Treatment of Paroxysmal Tachycardia.**—Savy refers to a few cases on record in which an attack of paroxysmal tachycardia was arrested by accidental vomiting after which the patients learned to induce vomiting systematically to arrest the attack. The pulse in one case dropped in thirty seconds after the vomiting from 200 to 94, from 209 to 96, and from 200 to 80. The means used to induce vomiting seemed to be immaterial—tepid water, tickling the throat, ipecac, etc.—but ipecac generally proved most convenient, two or three tablespoonfuls of syrup of ipecac always answering the purpose. Laache's patient was able to arrest the milder attacks by holding his breath or applying heat to the precordial region. Apert's patient was also able occasionally to arrest an attack by holding his breath. Others have reported the effectual action of a fright, of prolonged inspiration, of an automobile accident, compression or faradization of the pneumogastric nerves—all acting in the same way by direct or indirect excitation of the pneumogastric nerve or its centers. The effect of emetics probably belongs in this category, but their action is much more reliable and effectual than any of the other measures, while they can be more systematically applied in treatment. He has been unable to find any cases on record in which the attack was arrested by vomiting occurring spontaneously.

34. **Injurious Effect on the Kidney of Imperfectly Cooked Albuminous Food.**—In the experiments on rabbits and guinea-pigs reported the animals were injected subcutaneously with a maceration of meat in one-half part water, or with meat juice, egg albumin or milk, the aim being to determine the effect on the kidneys of albumin of animal origin. The effect was estimated by the albuminuria which almost invariably followed, its promptness, intensity and duration paralleling the congestion and other evidences of injury of the kidneys found on dissection of the animals. By this technic the influence of the digestive apparatus was eliminated. The results seem to demonstrate that raw animal albumin has always a decidedly injurious action on the kidneys, but this injurious action is nullified if the albumin has previously been in sufficient contact with the gastric juice. When the albumin is cooked, the gastric juice has to act on it for some time before it can be absorbed, and thus it is rendered non-toxic for the kidneys; raw albumin is absorbed too rapidly for it to feel the action of the gastric juice. The practical conclusions of the research are that uncooked albuminoid foods should never be taken by persons with kidney trouble, especially rare meats, raw milk and eggs with the white still transparent. Even raw milk, the authors state, may do more harm than well-cooked meats. The research also demonstrated, they add, that the organism seems to become accustomed to the nephrotoxic action of the albuminoids in time, and consequently it is best to keep up a regular ration rather than to permit great fluctuations, as for instance, ingestion of meat by a vegetarian. The fact that the same signs of an injurious influence were evident in the liver as well as in the kidneys in this research indicates, they think, that the conclusions probably apply to persons with liver derangement as well as to those with nephritis. The ability of the stomach to digest albuminoids is thus an important factor in nephritis as insufficient gastric digestion allows them to be absorbed in full toxic intensity.

38 *Gastric Amyxia: Lack of Gastric Mucus. (L'amyxie gastrique.) L. Cheinisse.

38. **Lack of Secretion of Mucus in the Stomach.**—During the last four years several articles have appeared on the pathologic absence of secretion of mucus in the stomach. The term "amyxorrhea" has generally been applied to the condition but Cheinisse comments on the absurdity of this term and proposes calling the condition "amyxia." The lack of the protective coating for the stomach walls afforded by the layer of mucus, explains a number of morbid conditions, especially in hyperchlorhydria. Schalij reported last year some cases in which the symptoms were those of hyperacidity, but one hour after the test meal the acidity was scarcely above normal while the lack of the protecting mucus explained the disturbances. Kaufmann found that silver nitrate relieved such patients, which fact he explains as due to the action of this drug in stimulating the production of mucus. Schalij found that oil seems to replace the missing mucus and cover the stomach mucosa with a bland protecting coating. The oil has to be ingested before eating; otherwise it only floats on the surface of the stomach content and does not come in contact with the mucosa. He has his patients take from 1 to 5 c.c. of olive or almond oil before meals, increasing the dose to 10 or 15 c.c. at need. Cheinisse remarks that gelatin or any similar substance might be used in the same way to advantage as a substitute for the oil. The benefit from bismuth may be due to its stimulating action on the secretion of mucus. Recent experimental research by Dubus seems to have established this; the bismuth not only promotes the secretion of mucus but the mucus in turn causes the bismuth to adhere to the walls of the stomach. All the data at present on hand in regard to gastric amyxia, Cheinisse adds, harmonize with what Turck has published in respect to the factors concerned in the healing of peptic ulcer.

43. **Senile Phthisis.**—Staehelin refers to the cachexia sometimes encountered in the elderly and possibly ascribed to

imately the same in the cadaver as in the monkeys. If the human brain should prove as tolerant as the monkey brain surgical procedures in this region will be much facilitated by this technic.

82. Operative Treatment of Gastric Ulcer. *Payr insists that operative measures for gastric ulcer should be strictly individualized for the character and location of the tumor.* He believes in more *general resort to resection rather than the routine gastroenterostomy. The latter is by no means always* successful in curing all *disturbances. The main argument in* favor of resection, however, *is the discovery of signs of a* malignant tendency in the *assumed benign gastric ulcer. In* more than 25 per cent. of his *cases of callous and other gastric* tumors the microscope *revealed carcinoma cells* somewhere in the resected patch. *Transverse resection leaves conditions* quite different *from those after excision; patients scarcely* ever vomit after the *former with the axial coaptation of the* stumps, far less *often than after a gastroenterostomy* or excision.

84. Leg Sign of Tetany. *Schlesinger has discovered a* phenomenon which he thinks *is destined to prove an instruct*ive sign of tetany in the *intervals between the attacks.* It is connected with flexing the hip-joint; as the patient reclines, if the stretched legs *are passively lifted the knees* show a tonic muscular *spasm of extension while the foot* assumes a position of extreme *supination or extreme* pronation. The phenomenon is also elicited *spontaneously* if the patient sits up in bed or, when standing, bends forward at the hips. The tonic *spasm is preceded by paresthesia in the limb.* On the other hand, pressure *on the* nerve trunks *or* kneading massage of folds of the skin has no effect in *eliciting* the sign. It parallels Trousseau's phenomenon, *occurring likewise* between attacks and on the *same side. The leg phenomenon* had been found pronounced in four *cases* of tetany at date of writing, both in children and adults. *In one case* mentioned the patient had no spontaneous contractions in the legs otherwise.

The Automobile

FOR THE PHYSICIAN

As a part of his Professional Equipment and as a means of Pleasure and Recreation

---

THE AUTOMOBILE IN PRACTICE

COULD the practitioner segregate his practice and confine it within certain limits, the condition would seem ideal; but the harder he works and the more skill he acquires, the wider becomes his circuit. The exigencies of practice in a large city, therefore, necessitate some other means than the horse and carriage for him to reach his patrons. Although I had driven horses for twenty-five years, I turned to the automobile in 1902.

EARLY EXPERIENCES

My first venture was a single-cylinder machine (109*). The trials I had cranking it in both warm and cold weather make me unhappy now when I think of it. Three weeks after I had become its owner I became ambitious and started with my wife for a tour expecting to go to Buffalo. It began to rain shortly after we started and we ploughed through mud and water some twenty miles until, on a railroad bridge, I thought I had a favorable place to oil up. I stopped the machinery but, despite all my efforts, I could not make it go again. Our auto journey ended by our being towed to Trenton, some six miles away, behind a coal wagon. I shipped the car to Cleveland and took the remaining portion of the trip on the less exciting but more reliable train.

Reaching Cleveland and ascertaining that the machine was in good order, we started again, this time in central Ohio through clouds of dust. After a ride of 70 miles the wheel of the water pump was broken off and again we had to ship the car back to Cleveland and take to the train. The vagaries of this machine were so numerous and trying that I finally disposed of it. It made so much noise that I never had any difficulty in letting my patients know that I was coming.

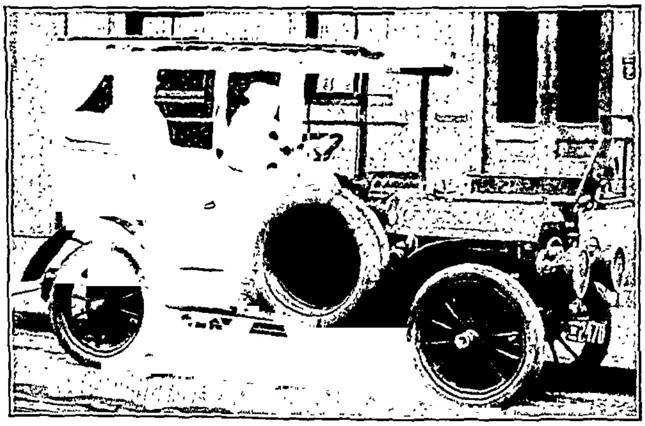

Fig. 1.—Demillmousine (114) of Dr. E. E. Montgomery, Philadelphia.

My next two ventures were runabouts (110*), two-cylinder machines. As I made a contract with the person from whom I purchased the machine that he was to take care of it, make sure that it was in order and if not get me another in its place for a certain sum each month, I had less trouble with this car. It was rather light weight, however, and as I was pretty heavy, occasionally an axle would break.

I then went to an electric (111*), which rode beautifully, was ever ready to go, was noiseless, but very limited in its speed and still more so if the batteries had run a little while, so that I found myself following rather than leading—an unsatisfactory position for an ambitious man. I therefore disposed of the electric and secured a touring car (112*). This car proved more satisfactory, in that it enabled me to afford my family and friends pleasure while I was traveling about the city for business. With this machine the tire problem was the greatest, owing, I am now convinced, to the want of care on the part of the chauffeur. On one journey of 20 miles we blew out four inner tubes and finally ran for a time with the tire collapsed. While going at a pretty fair speed my companion gave an exclamation as he saw the shoe which had come off running ahead of us and he was certain the entire wheel was gone.

TRIES A STEAMER

In order to leave no variety of machine untried, my next venture was a steam machine (113). Until I became acquainted with this I had so many unusual and unpleasant experiences that my family rather looked for me to undergo premature cremation, especially as I attempted to ignite the pilot light without raising the hood, and the accumulated gasoline exploded in my face, taking off most of what little hair I had left. I found out, however, that such an occurrence was unnecessary and due only to my stupidity. The machine did me more service than any other of the same class I have ever had. It rides beautifully, climbs the steepest hills without the slightest difficulty, and as it is entirely controlled by the throttle, it is capable of moving from a speed of two to one of fifty miles an hour by the motion of the handle governing the latter. The driver of a steam machine must keep his mind on what he is doing; he cannot go wool-gathering, as he must constantly remember that there must be water in the boiler and not too much of it, and that there must be satisfactory steam pressure and sufficient pressure on the gas. To watch all of the many gauges, as well as the road over which one travels, to say nothing of the vehicles and other travelers, certainly suffices to keep the driver wide awake.

PROTECTION AFFORDED BY CLOSED CAR

After recurrent attacks of grip, two of pneumonia, middle-ear disease and a mastoid operation, I began to realize that the human machine I possessed needed more protection, so my next venture was the machine (114) a picture of which accompanies this article. This is a rebuilt 1906 machine. It had seen considerable service before I got it, but it has traveled over 10,000 miles since with scarcely any trouble except that incident to tires.

The weight of the machine, being a metal body, necessarily makes tire wear great, but I do not know that the cost of its up-keep is any greater than that of much less reliable machines. It is a satisfaction to know that one has a machine that is ready for work and is almost sure to take one to one's destination and home again.

GRATIFYING ADVANTAGES

The automobile adds greatly to the comfort and pleasure of the physician: it enables him to extend his practice greatly and to afford pleasure and gratification to the members of his family which are utterly impossible by any other means of locomotion.

E. E. MONTGOMERY, M.D., Philadelphia.

---

* For names of machines, see explanation in Editorial Department.

FRICTION DRIVE

After reading each of the automobile numbers and nearly enough catalogues to make up the deficit in the post-office department, I decided to buy—as much through the influence of last year's Automobile Number as anything. Also having heard so many owners of small cars say, "When you buy, buy a good one," I decided to buy a friction-driven touring car (149). I ordered my car in March, but did not get it till June, which perhaps was a good thing for the car, as the roads were fine at that time. The agent came and helped unload the car and in two hours took the train for home. So much for training. I wrote to the company for their instruction book and the instructions were to wait, as the book was not out. The last time I wrote, in August or September, it was not out, and I am still waiting. So much for instructions—but the experience! Say! The experience was here to stay and a new issue each day. I suppose my experience was very similar to what all new owners have had with the exception of (or maybe better say addition of) the friction-drive. So I shall confine myself to the friction-drive.

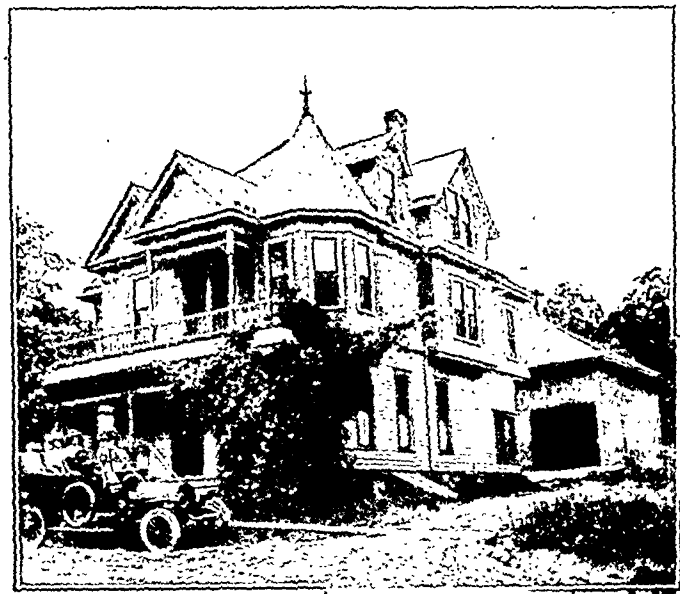

Fig. 2.—Automobile (149) and residence of Dr. E. A. Cantonwine, Parkersburg, Ia.

To start with, the most of my troubles could have been avoided if I had received some instructions with the machine. There was more friction than drive to start with, but, like everything else about the drive, this was simple when you knew how to remedy it. There is a certain amount of wear on the friction-rim at all times due to the outer and inner sides of the rim having to travel a different distance on the disc. This tends to heat the disc and, with a little slip, enough heat is developed for an automatic foot-warmer, that is, a warmer of mind and body.

I had a new catch made for the speed lever so that it gives me more speeds and wears the disc surface even, which will save trouble by preventing ridges. The expense of the drive has been the welding of one brace-rod. The fiber rim will soon have to be replaced, which will cost about $3. The disc is as good as new. The friction drive is all right, but I believe it requires more attention than a shaft drive. It makes up for this by the saving on the rest of the machinery. There is no jerk in stopping and starting, the speed can be increased gradually and the driver can set his speed according to the road. Sands and hills and mud, of which this part of Iowa has its share, have never stalled me so far. If they ever do I don't believe it will be due to the friction drive.

E. A. Cantonwine, M.D., Parkersburg, Ia.

BASEMENT AN IDEAL GARAGE

Any physician, almost, can buy a machine but there are few who can afford to pay the constant repair expense charged by the average garage. The basement garage has proved to me to be the most convenient arrangement for the busy physician. The basement garage is accessible without leaving the house and any physician can slip on a mechanic's suit, go down and in a few minutes repair something which he would otherwise be obliged to bring into the shop and pay perhaps more than he had earned that day.

With this scheme the machine never freezes, is easily washed, the oil lubricates better and any insurance company will allow a machine to be kept in a basement if the gasoline is kept in an underground tank or in the machine. A runabout kept in such a garage is now in its fourth year of constant use with promises of many years of service to come. The accompanying illustration shows the advantages of such an arrangement.

J. B. McNerthney, M.D., Tacoma, Wash.

A HIGH-WHEELER FOR WINTER AND A PNEUMATIC FOR GOOD WEATHER

Previous to April 1, 1907, I used, in my practice, two horses valued at about $500. Then I bought a 10 h. p., air-cooled, two-cylinder machine (122) with hard rubber tires. I kept accurate account of expenses for two years.

A CAREFULLY KEPT EXPENSE ACCOUNT

The total expense was $293.29, which averages $146.64½ for one year, about $12.23, for one month, and $2.82 for every seven days. This is cheaper than shoeing and feeding one horse and keeping buggies in repair. In this total expense I included $58.48 for gasoline; two pairs automobile gloves: two rubber-plush blankets; twice retiring the wheels; all the lubricating oil necessary; replacing two motor-shafts, which were $20 each—said to have broken from "crystallization," but in my opinion, from a flaw in the steel; replacing two sets of worn out gear sprocket-chains; also batteries, carbid, licenses, tags, etc.; in fact, everything necessary to run the machine for two years. In these expenses the driver is not included because I have the same man I had when I drove the horses.

In the winter of 1907-8 I could not use the machine for four weeks on account of snow and sleighing. In the winter of 1908-9 I used horses three weeks in sleighing. With these exceptions I used the machine to do all my work. I am sure that I did my work in one-third the time it would have taken with two horses.

In my experience of two years with the car I found I had a very serviceable machine; but, like all automobile enthusiasts, I wanted more speed, so, on May 14, 1909, I bought another car (123), a 20 h. p., water-cooled, four-cylinder car. I used this machine until about the middle of December, 1909, when I put it in storage. I had the motor dissected and examined and cleaned and found it in perfect order, except that the connecting rods were slightly loose. At this time my speedometer registered 3,129 miles. In these seven months my total expenses were $128, which averages $18.29 a month, or, per mile, about .041 cent, not including tolls, which in Pennsylvania are an outrage to the automobilist. On several long trips I used 5 gallons of gasoline to each 100 miles traveled. In this period I had five punctures, each caused by a nail or tack. One tire still holds the air that was pumped in when I purchased the car.

USES HIGH-WHEELER FOR WINTER WORK

At a cost of $7.35 I changed the single rumble seat to a double rumble by having the middle of the back sawed apart and a piece of board joined to the sawed ends, retaining the curve, and a new cushion placed on the seat and back on a new board.

With this car I have climbed, in high gear, steeper hills than the majority of the forty different cars owned in this place of about 10,000 inhabitants. One unnecessary expense was a top that I used the first day. Since I stored this car (123) I am using the old one (122) again, and will continue to do so until pleasant weather. I have discovered that there is less money invested in these two low-priced cars, for all the years' service and pleasure, than the same amount put in one high-priced car. The cost of upkeep is likewise less per mile in both than in a higher-priced car. A. C. WENTZ, Hanover, Pa.

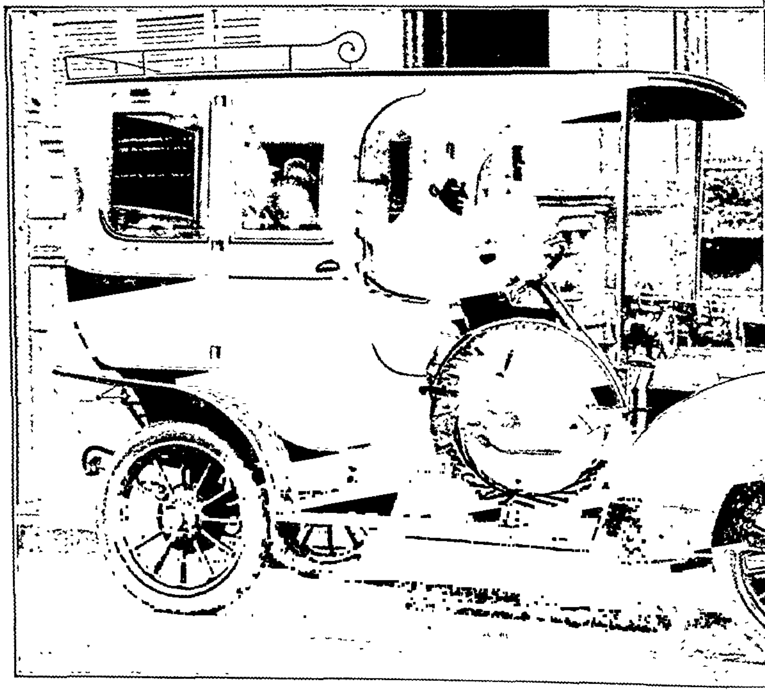

Fig. 4.—Car (117) used by Dr. James M. Anders since April, 1907, until the present. On the whole, the car has been quite satisfactory, although the body is perhaps too heavy for the chassis—a combination of conditions that is a bit hard on tires.

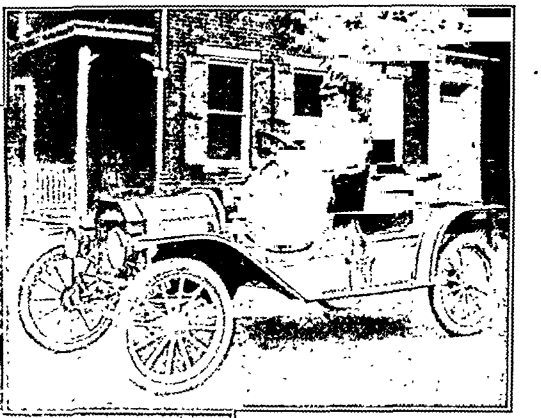

Fig. 5.—Dr. A. C. Wentz, Hanover, Pa., in his runabout (123 *).

THE STEAM AND THE GASOLINE CAR FOR THE PHYSICIAN'S USE

HAVING lost my horse, and declaring that I would never own another one, in March, 1904, I bought a steam runabout (126 *). For seven months I did all my work and drove to neighboring cities when I pleased, covering, on an estimate, 5,000 to 6,000 miles, at a cost of $1 day. In other words, the expense was the same as that of the horse. As I understood my car thoroughly, I had no trouble whatever outside of occasional tire troubles.

The next two years I used the car, but kept less accurate account of expense. I think that a dollar a day would cover all. The car, being older, required more repairing, but as I didn't run nearly as many miles I kept down the expense.

The three seasons that I used my steamer taught me that for a physician's use steam was not entirely satisfactory. A steam car has to be kept alive all the time it is in use; so that, when making calls, the pilot light, which must burn all the time, gets badly on one's nerves; and as the car gets older, and the pilot light more cranky, I would often start on calls without the car rather than put up with the worry about the pilot while making the call. I understand that in later models of this make of car this trouble of the pilot light has been done away with.

Another trouble with a steam car is that unless it can be kept in a warm garage it is practically out of commission as soon as freezing weather comes. As I kept my car in a small shed that I built for the purpose, I had to use great care to draw out all the water at night, even disconnecting the steam-gauge, as water gets trapped in it and freezing ruins it.

Because of these troubles, in the spring of 1907, I purchased a two-cylinder 12-horse-power gasoline runabout (127 *), and I must admit that this car has been more practical for my work. To be sure, it has given more trouble than the steamer and has twice been towed home (which never happened to the steamer). But on the whole I prefer the gasoline car for a physician.

Last spring I had the misfortune to break the crank-shaft, and it was over four months before I could persuade the makers to send me a new one. Why makers should be so loath to supply one with new parts when the old become broken or useless is more than I can understand; here is a good argument in favor of buying an automobile that is made near one's home.

HERBERT W. MANAHAN, M.D., Lawrence, Mass.

THE CHOICE AND CARE OF AN AUTOMOBILE

Address Delivered by William E. Sharp, General Superintendent of the Armour Car Lines, Before the Englewood Branch of the Chicago Medical Society, at its Automobile Clinic,* held in Chicago, Feb. 1, 1910

WHAT I shall say will consist of reminiscences from my five years' experience driving a pleasure car (104) beginning with a "one lunger" (103)—and at the outset I have to say that I do not agree with the physicians in all cases, because when you get a "one lunger" you send him away to the mountains, while it was my experience that it was better to stay on a level road.

About a year ago I was appointed a member of a committee o investigate the subject of automobile trucks for commercial use, and through this investigation I acquired what little knowledge I have on the subject of designing an automobile. During our investigation we visited the most reputable manufactories of automobiles in this country, as well as some of those that have not, and will not have, a reputation.

At the Paris Exposition in 900 France had the best hibit of gas engines for tomobile use, and the ingenuity displayed in design was a surprise to gas engine manufacturers; but during the last ten years the American automobile manufacturers have made wonderful progress, and to-day there can be no doubt that the American-made automobile is second to none; in fact, there is no need to go abroad to buy a car of the highest type and with the best appointments.

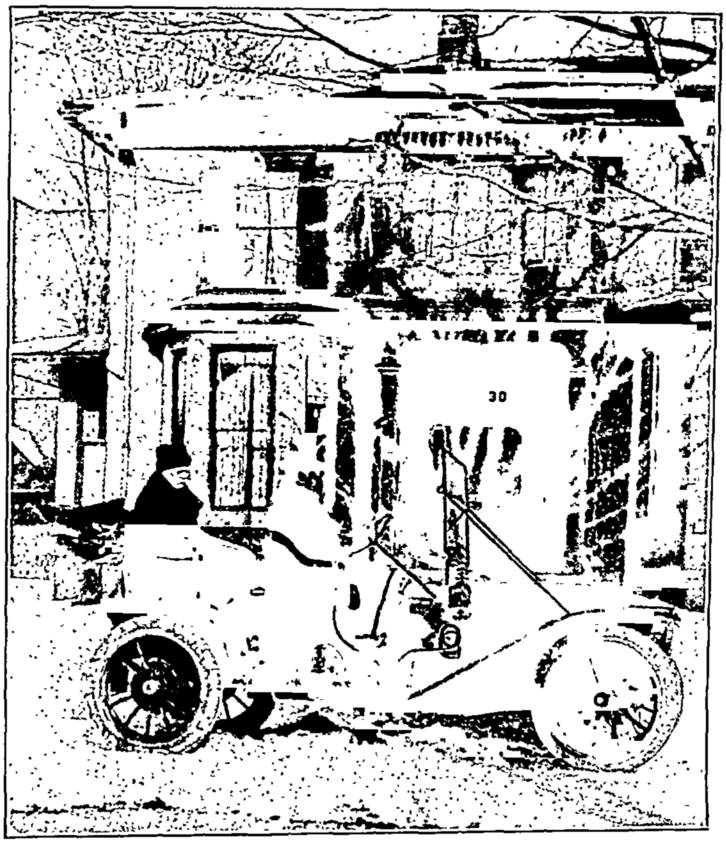

Fig. 6.—Dr. Adam H. Wright, Toronto, Canada, President of the Canadian Medical Association and Professor of Obstetrics in the University of Toronto. This photograph, taken Feb. 14, 1910, shows the car (107) in front of the house and office. It is a four-cylinder, thirty horse power car. There has been an unusual amount of snow in Toronto this season, there being on an average over one foot on the ground when this picture was taken. The car was not out of commission on account of snow for five minutes during the winter. The chauffeur was accustomed to horses all his life, and was a coachman in England for fifteen years. He came to Canada about three years ago because automobiles had become so common in England. He was Dr. Wright's coachman for about two years. When the horse was discharged and the car came, last September, he reluctantly took charge, soon learned to run it, has pretty well learned its mechanism, and now would not go back to horses on any account.

HOW TO SELECT A CAR

It does not follow, however, that anything in the shape of a gasoline tank mounted on wheels, making a hideous noise and giving forth an offensive smell, should properly be considered an automobile. Therefore, the first thing we will consider, as laymen, is the selection of a car. It is, of course, understood that it must be a good one. But how shall the average layman, who is not familiar with the automobile, knows nothing of its design or construction, answer this question? To which we reply: by purchasing from a reputable maker, one who is a manufacturer and not an assembler; one who has worked out all of the problems for himself, instead of copying from what others have done; one who is reliable, and who has a reputation and investment which make reasonably sure that he will still be in the business when your car gets old and becomes worn, needs repairs and an occasional new part; also, one who maintains his own branch houses, where you can deal directly with the manufacturer of your car; whose motto is, "A square deal, even in the automobile business."

Too often the average layman going out to buy a car looks only for the rated horse power, the wheel base, and the maximum speed that the car will make per hour, and completely ignores, or does not understand, the important points on which he should base his selection, which, in the first place, depend very much on the particular service to which the car will be put.

The car with the long wheel base makes the most desirable car for a country road, particularly rough roads. On the other hand, it is more difficult to maneuver in a crowded street. A heavy car is by all means the easiest riding car, and not much, if any, harder on the tires, providing, of course, that the tires have been proportioned to the weight of the car. On the other hand, a heavy car does not respond to the moves of the throttle as quickly, and it can hardly be expected that an engine, unless of size out of all proportion to the car, is going to accelerate a heavy mass as quickly as a light one. Again, the heavy car is not affected by small obstacles; it moves over the road more smoothly, and with uniform speed, and it is of itself a fly-wheel.

While it is fair to assume that the cost per running mile is greater for the heavy load than for the light one, this statement is subject to qualification, for with a given wind resistance the heavy car, when under motion moves along with nearly the same power as the light one. This applies, of course, to level roads. Climbing hills the lighter car has somewhat the advantage; but also the disadvantage of being unable to stand the rack and strain of service. The very thing that gives the car weight also gives it strength.

ACCESSIBILITY OF ENGINE

Perhaps the most important point to be considered in selecting a car is accessibility of all parts, or, in other words, the ability to remove any one part of the car without disturbing all others. On this point the average salesman will disagree with you, having you understand that his particular make of car never needs to be dissembled, that nothing wears out, that no accident can possibly happen—a consummation devoutly to be wished, but one which can ne'er be hoped for.

One must be able to get into the crank case without disturbing the other parts, for the bearings will eventually wear and require adjustment. One must be able to dismount the magneto, or the circulating water pump, without being required to remove the radiator. The oiler must not be in the way of any of these operations. Not that the oiler is in itself complicated, but it has a great many attachments in the way of small pipes, which should always be tight and shipshape to insure perfect results. The transmission as a whole should be demountable without the necessity of disturbing any of the rest of the assembling, for transmissions are subject to accidents, and more often to flagrant abuse. The manner in which the gears are shifted may subject them to strains far beyond the endurance of any metal, hence the transmission should be located so that it is easy of access and may be entirely removed without disturbing any other parts.

---

* A general discussion on the subject followed the reading of this paper and an abstract of this is presented at the end of the article.

The time required for the clutch to slow down after the release, so that the two gears about to be engaged are of the same speed, varies with different cars—not only different makes, but individual cars of the same make. All this must be learned by the driver. With a little experience, and having once learned it, there is no excuse for the slamming method of shifting gears, which attracts attention from the sidewalk, encourages profanity, and is a fruitful source of expense.

One of the first questions usually asked, and least understood, is, "What is the rated horse power of your car?" The answer is "30" or "40," or whatever may be the rated horse power of the car, and 40 seems to be a familiar term; but your question has not been answered. It is not so much a question of the size of the cylinders, or how much gas you explode, or with what force the explosion takes place. Power can be determined only by the amount of force delivered at the rear wheels, and let it be understood that in testing the power of an engine only the full capacity at any given speed is considered, it being obvious that under the throttle it is not a truth-teller, its performance in this instance not being in any way an index of its possibilities; hence, as an automobile is used but a fraction of its time to its full capacity, it is not expected that a testing load shall be the daily stunt of any car, for more than ninety per cent. of the time the car calls for less than half the rated power of its engine, and so for that ninety per cent. of the time one engine is about as good as another. But within the ten per cent. of the time remaining, the car undergoes difficulties which call for Herculean efforts, and unless successfully surmounted the other ninety per cent. is of little value.

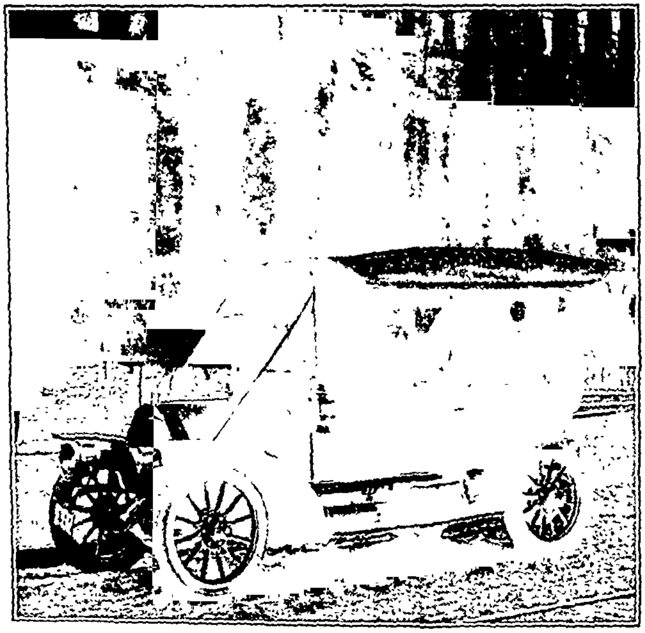

Fig. 7.—Forty horse-power machine (174) used by Dr. John G. Clark, Philadelphia, Professor of Gynecology in the University of Pennsylvania. The picture was taken in front of the main entrance of the University Hospital.

All physicians know the immense reserve of the human power plant, seldom used, but necessary for its preservation in time of trial, and the good designer, ever responsive to the hints which Nature gives him, builds his car along liberal lines, with plenty of power, with weight enough to carry it, and so distributed that it will not be topheavy. To get plenty of power without increasing the dimensions of the engine beyond a reasonable limit, the good engineer takes into account these days of stress and trial, and makes the conditions under which the engine operates the basis for his work, and except in rare instances, when the car is run at its highest possible speed, which also calls for power, the times when its engine is running at its hardest load is when it is running also at its slowest speed. Therefore, those factors which fix the power of an engine at high speed are not the most important, but those which restrict its output at low speed and heavy explosions become of paramount importance.

The high speed engines are of necessity high compression engines, and their performance is not so good at low speed. I have in mind an engine developing 34 h. p. at 1,600 revolutions per minute, and 12 h. p. at 300 revolutions per minute. By raising the compression ten pounds, the h. p. at 1,600 is raised to 36½ or 37, but drops some 4 h. p. at 300. It is the part of a good engineer so to design his engine and his car that it will perform well when under its hardest load, which is in low speed.

The friction of the cylinder walls, then, is a larger factor than the inertia of the reciprocating parts, and any method of construction which will diminish this wall friction in a large degree is preferable. Also, the friction of the main bearings is a large factor under heavy explosions, a much larger factor than under the more rapidly recurring blows of the lighter explosions due to high speed. Hence, any design which lessens this friction is preferable.

POINTS ABOUT ENGINE CONSTRUCTION

It has been the belief of some engineers, and the fixed conviction of the layman, that rapid flame propagation is good for the development of power, a truth which, stated without qualification, may lead to great error, for if this were a truth unqualified, an instantaneous flame propagation would, of course, be better than one which was dragged out. Ergo, a spark plug in the head near the center of the charge, where the flame would be propagated but a short distance, would be the desirable construction. Well, it is desirable construction for high speeds, but at high speeds most any construction would be satisfactory, while at low speeds we have radically different conditions.

The time required to propagate a flame throughout the mass of gas in an ordinary automobile cylinder varies from 1/600 to 1/300 part of a second; during only 1/300 part of a second the crank has traveled when the car is doing its heavy work at speeds less than 20 miles an hour, about 15 degrees. If the propagation of the flame is shortened to 1/600 part of a second, the crank under the same circumstances has traveled approximately seven or eight degrees, and the full force of the explosion is expended on the crank at a time when it has almost no turning moment, and if the sides of the cylinder are not sufficiently cool to permit of proper lubrication the gas loses its pressure before the crank has reached that portion of the stroke where the piston pressure is most effective. If, however, there is a continued rise in the pressure up to the time the crank has passed 15 to 20 degrees of movement, the piston is then traveling at a good rate of speed, and the contracting effect, due to the cool cylinder walls, is much lessened, and we have a large value of turning moment. By setting the spark plug in a port to one side of the cylinder, and proportioning the distance so that under these hard loads the flame is propagated to reach its maximum when the crank has traveled through about 25 degrees, we have a much more sustained pressure on the piston and a more nearly continuous torque on the crank.

Now, then, if the cylinder is set tangent to a circle concentric with the crank shaft and of such diameter that the connecting rod is parallel with its axis, at the time the explosion has reached its highest value, then we have at that time no friction in the cylinder due to side thrust, whereas if the cylinder is radical to the crank shaft the friction on the cylinder walls reaches considerable value when the crank has passed through 25 degrees.

repair shop. I take care of my car (170) myself and I can get out of trouble without assistance. One should have a little shop with a little lathe and when a casting or some part is broken be able to fix it up.

Dr. Charles Henderson Miller: From what I can learn it would be mere folly to argue against the use of an automobile for a doctor's work. I do not hear any of the men who have driven machines say they would care to go back to horses. My advice to a man thinking of using an automobile would be to buy one as quickly as he can afford to pay $1,000 for a machine but get a good one. If he has a family, I advise that he get one large enough to carry more than two passengers. It would be a good plan to get one that he can use as a coupé in the winter time, if he wishes, and convert into a tonneau in the summer time. Every doctor should have a book telling him how to take care of his car. Excessive power is neither desirable nor necessary. A maximum of 20 h. p. is sufficient if the weight of the car is not too great, and the greater the horse power the greater the weight of the machine. It is just as available on the road for hills and otherwise with the lighter power. The gasoline engine of this car should always be in front—never under the seat. It is a constant source of concern and requires a good deal of attention. I am not positively decided as to the best quality of oil to use. There are a number of different makes and grades. I am using oil that costs about 20 cents a gallon. The cost of gasoline is practically nothing. A car of this kind will save at least 50 per cent. of the time of the physician using it, in other words, he will have half of his time for leisure and yet do the same amount of work.

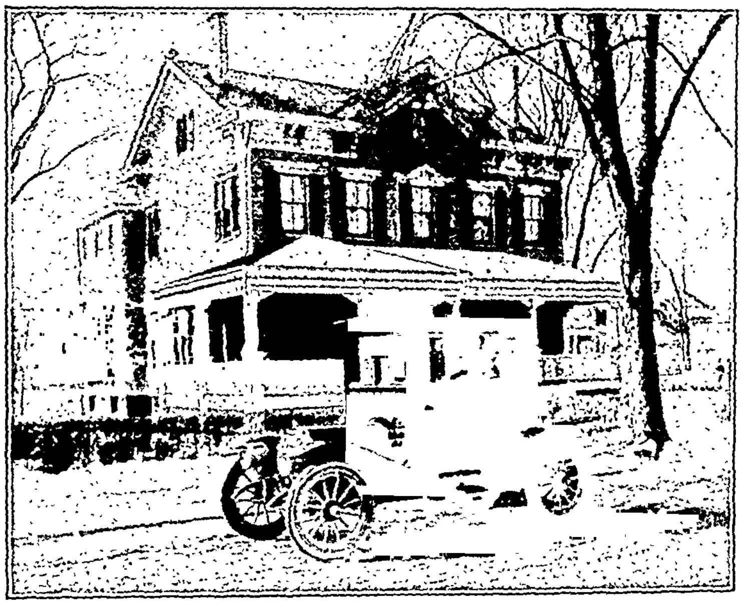

Fig. 10.—Runabout (124), office and residence of Dr. F. C. Ard, Plainfield, N. J. The coupé body was added to the car for protection from bad weather in winter. It does away with the necessity for fur coats and heavy clothing. It is removable for summer use, when the open body is replaced.

There is a great deal to be said about the way a car is cared for to eliminate trouble. The first thing is to have the car properly tired. Good tires are money-saving investments. It is well to have a vulcanizing equipment so that when you see a hole working into the tire you can seal it up. The tires on my car have run seven thousand miles and I think they are good for several thousand miles more. I take care of the car myself. Regarding the maximum speed one should travel, I think there is a constant tendency to want to go faster than is necessary or safe; and the life of the car is shortened by fast driving. I am exceedingly well satisfied with my automobile (171), although I paid the price of learning how to run it in three years' use and misuse of this car's immediate predecessor.

Dr. C. H. Lovewell, Sr.: I do not own an auto and perhaps never will own one. I know a machine is a very fine thing, but you pay for it each month. I have owned in all six horses. In my first year in Chicago (1875) I kept my horse in the livery stable when business was fair, and when business was slack I put the rig in the coal shed, to go back again to the livery when business warranted. After a time I drove two horses and enjoyed driving them as well as any of you doctors enjoy your autos. The expense for the team was about $35 per month plus $20 per month for a stable man. I have owned no horse now for several years.

Now, I know just what it costs me to make a visit. I can make one call by trolley car at any time for ten cents in this section of the city. Sometimes I can make two or three calls for ten cents, and I am ready to start at any time during the twenty-four hours in fifteen minutes. I doubt whether there is a physician in Chicago who can make a visit for less than twenty-five cents in an automobile.

Mr. W. E. Sharp: As to the relative merits of the assembled car and the car sold by the manufacturer, it is a well-known fact that the majority of the automobiles offered for sale are assembled cars, but it is a better business proposition to purchase direct from the manufacturer, as he has the benefit of experience in the various stages of development. If he is a reputable manufacturer you have his guarantee back of the car you purchase, and it is fair to assume that he has some pride in his business, and you are, therefore, assured of his cooperation and assistance in all of your troubles and in the repairs and up-keep. It is true that one of the best gas engines on the market, until very recently, was not owned or controlled by the automobile company, but was sold and used in various types of cars, but it does not follow that this would make a satisfactory car. All other parts as well as the engine have to be correctly proportioned, and for that reason I can not agree that you can get an assembled car that will give the service as well as the one you purchase direct from the manufacturer. I spent some time visiting the manufacturing plants of the automobile companies, and besides the quality of the material used, and the character of the work done, I was impressed with the importance of the organizations for inspecting and thoroughly testing all parts separately and collectively. I also visited manufacturing plants where only parts were being made, and it did not seem to me that the same care was used in inspecting and testing, possibly for the reason that they were made to sell.

As to the quality of material used in the cheap or moderate-priced car, as compared with the higher-priced machine, it is possible that the same grade of material is used, but it is just as important to have the proper quantity as it is to have the proper quality, and it seems reasonable that you would get a better material in the high-priced car, for the reason that the cost of labor for manufacturing and assembling would be no more than it would be for a lighter car, the same amount of labor being involved in each case, and there is less liability to crystallization of parts where they are made reasonably heavy.

The best oil is none too good. It should be used in the proper quantities—better too much than not enough, although the excessive use of oil will cause trouble. All manufacturers have tested oils to find which will give the best service with his particular type of engine, and that is about the best indicator.

The electric car, of course, is only supposed to be a boulevard car, but it seems to me it would answer the requirements of the physician in his daily round of calls, and he would have the comforts of the automobile without the care that it required in driving the gasoline car. It is a fact well known to all that a gasoline power plant requires attention, and the preparing of the car for its day's work is necessarily dirty work, in which hands become soiled—and it is otherwise objectionable. All of these features, of course, are removed when a man employs a chauffeur.

As to the advisability of purchasing a cheap or light car, it is a fact that there are several light cars on the market that would give considerable service on the boulevards, but it does not follow that a man is going to buy an automobile and stay on the boulevards. He will venture on the country roads, in the majority of cases with his car overloaded, and while he will possibly have satisfactory results with a light car at the beginning, the car is not built to stand any such service, and for that reason it seems to me inadvisable to buy a cheap, light touring car, and that it would be better and cheaper in the long run to buy a car designed and built for general purposes.

repair shop. I take care of my car (170) myself and I can get out of trouble without assistance. One should have a little shop with a little lathe and when a casting or some part is broken be able to fix it up.

Dr. Charles Henderson Miller: From what I can learn it would be mere folly to argue against the use of an automobile for a doctor's work. I do not hear any of the men who have driven machines say they would care to go back to horses. It is a fact well known to all that a gasoline power plant requires attention, and the preparing of the car for its day's work is necessarily dirty work, in which hands become soiled—and it is otherwise objectionable. All of these features, of course, are removed when a man employs a chauffeur.

As to the advisability of purchasing a cheap or light car, it is a fact that there are several light cars on the market that would give considerable service on the boulevards, but it does not follow that a man is going to buy an automobile and stay on the boulevards. He will venture on the country roads, in the majority of cases with his car overloaded, and while he will possibly have satisfactory results with a light car at the beginning, the car is not built to stand any such service, and for that reason it seems to me inadvisable to buy a cheap, light touring car, and that it would be better and cheaper in the long run to buy a car designed and built for general purposes.

THE ADVANTAGES OF THE MOTOR-CYCLE

THE MOTOR-CYCLE IS THE KING OF THE ROAD

Getting there and back again—in this the motor-cycle has the laugh at them all. My patients telephone me from the country, "Can't you come on your flying-machine, Doctor?" and, behold, I am at the bedside of the patient before the telephone receiver is hung up. That is the trouble with the motor-cycle; one gets the speed mania. On a dry ordinary dirt-road, not too stony or uneven, one can travel at the rate of 30 to 40 miles an hour. This can't be said of the auto.

Look at the picture: I am called to see a patient in the neighboring village ten miles away. She had her first pain. I'll be there before she has the second one. When I come to the house of my patient I remove that duster, coat, cap and gloves and I'm presentable at any court. I left the dust behind me. Take notice of my scheme of combining the medicine-case, instrument case and sterilizer into one. It is made of copper and curved to fit the small of the back, where it rides most comfortably. It is fastened to the body with a leather strap which is easily detached from the case. It is 15 inches long, 3 inches wide, and 6 inches deep and if I need more room I can make use of the pockets of that coat.

MOTOR-CYCLE VS. AUTOMOBILE

	Motor-Cycle.	Automobile.
Classification.	Light weight, biped monorailer, great saver of power, wear and tear.	Heavy, clumsy, quadruped white elephant, 4 feet at 4 ever-changing levels, great loss of power, wear and tear.
Life.	Long-lived.	Subject to general debility early.
Vital organs.	Little predisposed to grave disorders.	Predisposed to expensive major operations at the machine shop hospital.
Heart.	In case of heart failure, disconnect engine, turn on foot power.	Call ambulance, chains and ropes; "dig up" and get the laugh.
Metabolism.	Normal absorption of oil and gasoline.	Deranged, fever high and drinks like a fish.
Feet (tires).	Long-lived, tetanus occasionally, use antitoxin early, prognosis good, $25 per pair.	Short-lived, susceptible to perforating ulcers and cancers; prognosis bad; $200 per set, price advancing.
First cost.	Sane.	Insane.
Second cost.	Normal.	An octopus monster.
Investment and Economy.	Good.	Poor.

Don't shy of the motor-cycle because it is a biped monorailer; that is the up-to-date feature and that is what makes the motor-cycle the king of the road. On a motor-cycle, your eyes are watching the road and your hands and feet are in constant relation with the mechanism of control and balance.

That is why you never lose presence of mind. That is what makes the motor-cycle safer than other vehicles. Being a monorailer, it gives you better choice and control of the road and better command of yourself and machine than can be enjoyed on any other vehicle that travels on terra firma. Then, too, this monorailer stirs up an enthusiasm that can be equaled only by flying in an aeroplane. It is enthusiasm that we all need. A good motor-cycle is no burden, and when it gets seriously sick on the road it can be wheeled or pedaled along as easily as a bicycle after the engine is disconnected. You need not call for a team of horses; you need no hydraulic jacks, no wrecking-crew. The ride on a motor-cycle is not to be compared to the rough, laborious and dusty ride on a bicycle.

My experience with a motor-cycle as a business proposition and recreation has been extremely satisfactory. It has proved a good investment, a money- and time-saver, and not until the automobile does away with its expensive tires and troubles, its complicated machinery, its great weight and its short life can it be a good investment for the country doctor.

I ride a twin-cylinder 6-horse-power chain-drive (159) in a hilly country with sand in the low places. The fine workmanship, the leverless grip control, the pneumatic [illegible]ing spring fork, the economy of space and symmetry of design on this machine are superfine, and I have yet to find sand deep enough and a hill steep enough to kill the engine on my cycle.

Doctor, if you are not too old and crippled with rheumatism, buy a good motor-cycle and enjoy your trips into the country in a way you never dreamed of. Keep the horse for muddy roads and snow-drifts. F. C. **Dolder**, M.D., St. Charles, Minn.

THE MOTOR-CYCLE

Being disgusted with the trouble and expense incident to keeping horses, in the spring of 1909 I sold my teams and buggies and purchased a three-and-a-half horse-power single-cylinder motor-cycle (118) and used it entirely in my practice. During 1909 I drove it over 2,000 miles at about one cent per mile with a repair bill of only $1.85.

To say that I am pleased with the machine is expressing it very mildly. Calls that used to be hard work are now pleasure trips and there is a fascination and recreation about the riding of a motor-cycle that I never found in any other sport. I can make my trips much quicker than with a team and I have more time in the office. I can go anywhere that there is a path at all, and, in case of emergency, can c[illegible] the prairie at a pace of 18 to 20 miles an hour, while [illegible] good roads I can easily run 30 to 40 miles an hour.

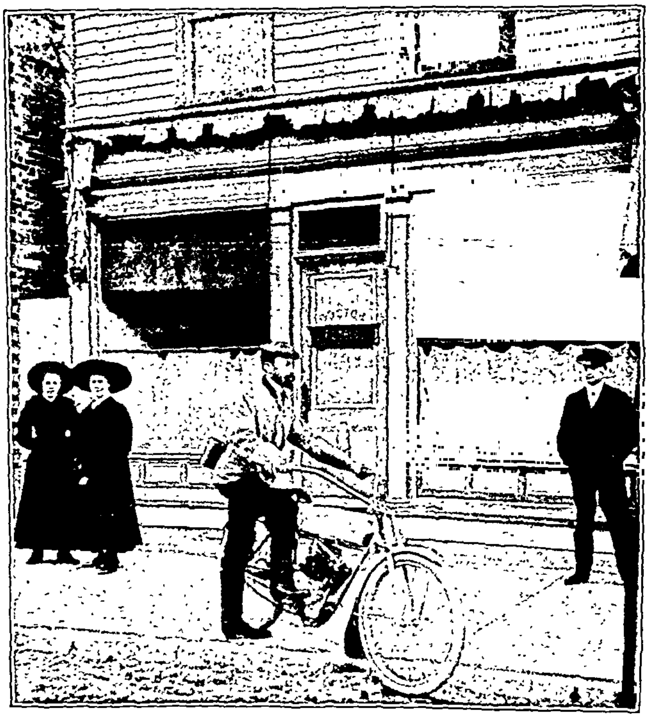

Fig. 11.—Called to see a patient ten miles away. Dr. F. C. Dolder, St. Charles, Minn., and his motor-cycle (159).

I always take entire care of my mac[illegible] I find it far less work, and work that I like better th[illegible] caring for horses. When weather prevents the running of [illegible] motor-cycle I, of course, have to hire a team, but find tha[illegible]en so the cost the year around of using the motor-cycle an[illegible]iring horses when necessary is far less than keeping a tea[illegible] my own and on the whole is many times more satisfactory[illegible]

I believe the wheel I have is as good as [illegible]re is on the [illegible]ket, especially for a beginner, as it is ver[illegible]mple of [illegible]tion and will stand a lot of abuse and h[illegible] [illegible]ing year, though, I expect to exchang[illegible] (119) on account of the many im[illegible] desire for more power that become[illegible] repair shop. I take care of my car (170) *myself and I can* get out of trouble without assistance. One should have a little shop with a little lathe and when a casting or some part is broken be able to fix it up.

Dr. Charles Henderson Miller: From what I can learn it would be mere folly to argue against the use of an automobile for a doctor's work. I do not hear any of the men who have driven machines say they would care to go back to horses. My advice to a man thinking of using an automobile would be to buy one as quickly as he can afford to pay $1,000 for a machine but get a good one. If he has a family, I advise that he get one large enough to carry more than two passengers. It would be a good plan to get one that he can use as a coupé in the winter time, if he wishes, and convert into a tonneau in the summer time. Every doctor should have a book telling him how to take care of his car. Excessive power is neither desirable nor necessary. A maximum of 20 h. p. is sufficient if the weight of the car is not too great, and the greater the horse power the greater the weight of the machine. It is just as available on the road for hills and otherwise with the lighter power. The gasoline engine of this car should always be in front—never under the seat. It is a constant source of concern and requires a good deal of attention. I am not positively decided as to the best quality of oil to use. There are a number of different makes and grades. I am using oil that costs about 20 cents a gallon. The cost of gasoline is practically nothing. A car of this kind will save at least 50 per cent. of the time of the physician using it, in other words, he will have half of his time for leisure and yet do the same amount of work.

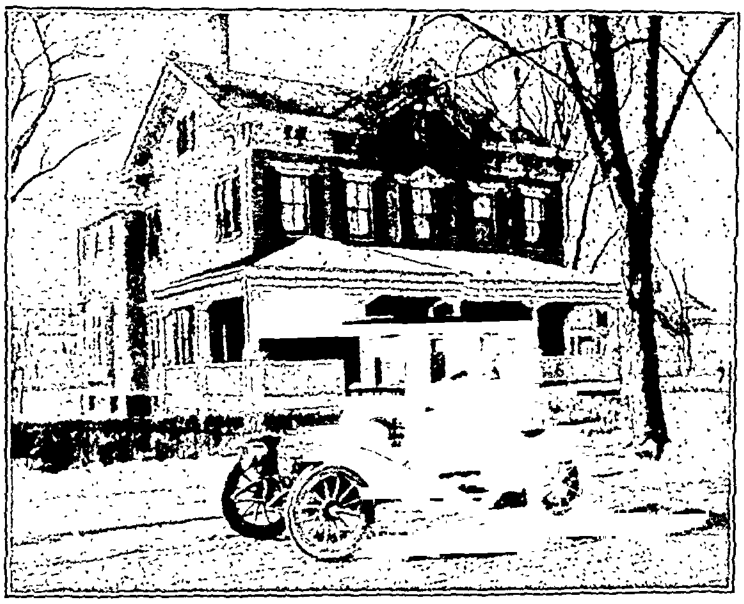

Fig. 10.—Runabout (124), office and residence of Dr. F. C. Ard, Plainfield, N. J. The coupé body was added to the car for protection from bad weather in winter. It does away with the necessity for fur coats and heavy clothing. It is removable for summer use, when the open body is replaced.

There is a great deal to be said about the way a car is cared for to eliminate trouble. The first thing is to have the car properly tired. Good tires are money-saving investments. It is well to have a vulcanizing equipment so that when you see a hole working into the tire you can seal it up. The tires on my car have run seven thousand miles and I think they are good for several thousand miles more. I take care of the car myself. Regarding the maximum speed one should travel, I think there is a constant tendency to want to go faster than is necessary or safe; and the life of the car is shortened by fast driving. I am exceedingly well satisfied with my automobile (171), although I paid the price of learning how to run it in three years' use and misuse of this car's immediate predecessor.

Dr. C. H. Lovewell, Sr.: I do not own an auto and perhaps never will own one. I know a machine is a very fine thing, but you pay for it each month. I have owned in all six horses. In my first year in Chicago (1875) I kept my horse in the livery stable when business was fair, and when business was slack I put the rig in the coal shed, to go back again to the livery when business warranted. After a time I drove two horses and enjoyed driving them as well as any of you doctors enjoy your autos. The expense for the team was about $35 per month plus $20 per month for a stable man. I have owned no horse now for several years.

Now, I know just what it costs me to make a visit. I can make one call by trolley car at any time for ten cents in this section of the city. Sometimes I can make two or three calls for ten cents, and I am ready to start at any time during the twenty-four hours in fifteen minutes. I doubt whether there is a physician in Chicago who can make a visit for less than twenty-five cents in an automobile.

Mr. W. E. Sharp: As to the relative merits of the assembled car and the car sold by the manufacturer, it is a well-known fact that the majority of the automobiles offered for sale are assembled cars, but it is a better business proposition to purchase direct from the manufacturer, as he has the benefit of experience in the various stages of development. If he is a reputable manufacturer you have his guarantee back of the car you purchase, and it is fair to assume that he has some pride in his business, and you are, therefore, assured of his cooperation and assistance in all of your troubles and in the repairs and up-keep. It is true that one of the best gas engines on the market, until very recently, was not owned or controlled by the automobile company, but was sold and used in various types of cars, but it does not follow that this would make a satisfactory car. All other parts as well as the engine have to be correctly proportioned, and for that reason I can not agree that you can get an assembled car that will give the service as well as the one you purchase direct from the manufacturer. I spent some time visiting the manufacturing plants of the automobile companies, and besides the quality of the material used, and the character of the work done, I was impressed with the importance of the organizations for inspecting and thoroughly testing all parts separately and collectively. I also visited manufacturing plants where only parts were being made, and it did not seem to me that the same care was used in inspecting and testing, possibly for the reason that they were made to sell.

As to the quality of material used in the cheap or moderate-priced car, as compared with the higher-priced machine, it is possible that the same grade of material is used, but it is just as important to have the proper quantity as it is to have the proper quality, and it seems reasonable that you would get a better material in the high-priced car, for the reason that the cost of labor for manufacturing and assembling would be no more than it would be for a lighter car, the same amount of labor being involved in each case, and there is less liability to crystallization of parts where they are made reasonably heavy.

The best oil is none too good. It should be used in the proper quantities—better too much than not enough, although the excessive use of oil will cause trouble. All manufacturers have tested oils to find which will give the best service with his particular type of engine, and that is about the best indicator.

The electric car, of course, is only supposed to be a boulevard car, but it seems to me it would answer the requirements of the physician in his daily round of calls, and he would have the comforts of the automobile without the care that it required in driving the gasoline car. It is a fact well known to all that a gasoline power plant requires attention, and the preparing of the car for its day's work is necessarily dirty work, in which hands become soiled—and it is otherwise objectionable. All of these features, of course, are removed when a man employs a chauffeur.

As to the advisability of purchasing a cheap or light car, it is a fact that there are several light cars on the market that would give considerable service on the boulevards, but it does not follow that a man is going to buy an automobile and stay on the boulevards. He will venture on the country roads, in the majority of cases with his car overloaded, and while he will possibly have satisfactory results with a light car at the beginning, the car is not built to stand any such service, and for that reason it seems to me inadvisable to buy a cheap, light touring car, and that it would be better and cheaper in the long run to buy a car designed and built for general purpose moves in throwing in and out the clutch and in changing speeds. Thus one will be better able to know when something goes wrong and where to locate it and possibly be able to adjust it before greater damage is done and save time and unpleasant annoyance.

C. H. Eidam, M.D., Lawrence, Mass.

CHOOSE A MODERATELY HEAVY CAR WITH A LONG WHEEL-BASE AND BIG WHEELS

My observation of automobiles began with their first appearance on Cleveland streets many years ago, but personal experience dates back about five years, when I bought a two-cylinder 18 h. p. touring car (175). My experience with that car I will not relate, because five years ago in motoring is ancient history, and because that machine was no more like the one I now drive than the Bungtown Accommodation resembles the Twentieth Century Limited.

GOING SLOWLY ON HIGH GEAR.

Last April I bought a 35 h. p. four-cylinder car (175) with baby tonneau or short coupled body. It is called a four-passenger car, but carries five comfortably, and can carry as many as will pile on. It has shaft drive, and selection type of transmission. It is said to be capable of a speed of 55 miles an hour. I never tried its speed limit but have driven it at forty miles an hour with five passengers up, which is fast enough for travel on any public highway by any one supposed to have regard for people's lives. This machine has three speeds forward and one reverse. While on the high speed one can slow down and creep along at the pace of a pedestrian, and thus, without changing gear, can pick his way through congested streets. It is claimed that this flexibility is due to an offset crankshaft and a straight line drive. I don't know why it does so, but it does it. In my daily round this machine plays with 20 to 40 miles of Cleveland's badly paved streets. Some days, with country trips, two or three times this mileage must be covered in short hours.

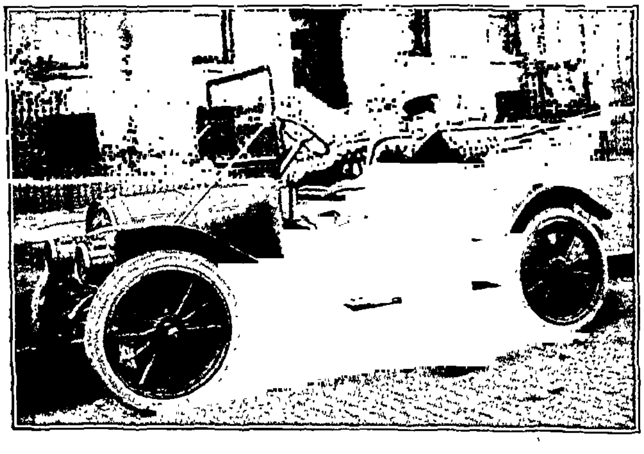

Fig. 18.—Dr. S. W. Kelley of Cleveland, Ohio, and his car (175).

ADVANTAGES OF LONG WHEEL-BASE

This machine has a wheel-base of 112 inches, and its pneumatic tires are 36 by 4 inches. I like this long wheel-base and the big wheels; and I like the short body, bringing the rear passengers forward of the rear wheels. I would not buy a short chassis or smaller wheels. Nor would I buy a light car. If I needed vibratory stimulation I would take it in some moderate and better regulated way than by riding daily in a light car. Nor do I think there is much, if anything, saved in tires by a light car that bobs about all over the road. I have driven this car more than six thousand miles on all but one of the original tires (176) and they appear good for more yet.

A GOOD WINTER CAR

This is a well-balanced car and will stick to the road and obey the wheel. I have driven it through the worst snow and ice of this wintry winter without skidding. Properly handled, these big wheels (which also insure plenty of clearance) and long wheel-base, will cross car tracks and turn at all angles on any street without skidding. The engine has run smoothly, quietly and powerfully.

Samuel W. Kelley, M.D., Cleveland, Ohio.

THE DESIDERATA FOR A PRACTICAL CAR

My original idea was to purchase a low-priced car to use until I could satisfy myself that an automobile would be practicable for me in particular. I obtained considerable service from my first car, a one-cylinder, 7 horsepower runabout (132). After using this car a year the main ideas in my mind were that I would never again purchase a chain-driven machine; that the body of the car should have protection by ample mud-guards, and a pan sufficiently large to keep the engine and transmission dry and clean. The car was not large enough to create a good appearance, and seemed overloaded with more than one passenger. My principal difficulties came from the transmission, owing to a poor design of high-speed clutch. The vibration of the single cylinder, though not hard on the occupant, was hard on the car, for lamps, mudguards, bolts, screws, etc., were gradually shaken loose.

The cooling of the engine was effected by the thermo-siphon system, which I feared might give me much annoyance by a winter freeze-up. A 50 per cent. solution of denatured alcohol entirely obviated this danger.

My second purchase was a second-hand, 20 horse-power, two-cylinder, two-cycle runabout (133), taken with something to boot, in exchange for my first car. The two-cycle engine has given almost no trouble, but consumes too much gasoline, in spite of careful regulation of the carburetor. The one great trouble I have had has been a slipping of the high-speed clutch—an intolerable nuisance. In other respects my troubles have been few, and easily remedied. If a man is to care for his own car he had best buy early certain accessories, such as a set of extension wrenches, files, soldering irons, vice, etc., for making small repairs. In case of serious trouble I have had the best results by taking the defective mechanism apart and referring the difficulty directly to the maker. On the road an extra shoe and a couple of extra tubes and spark-plugs seem almost indispensable. To me it is the delay when one ought to be riding, and clean, rather than the preparation and care at the garage where one can afford to be unhurried and dirty that make one dissatisfied with a car. I believe that the auto is practicable for the physician, and that it will become more so, for the great demand and the result of experience must produce a machine of greater and greater perfection. If I were buying again to-day I should select a shaft-driven car of medium grade and standard make, the main features of which had been tried out by a couple of years' use. I should want tires amply large, and lay very special stress on the accessibility of motor and transmission, and adjustability of wearing parts.

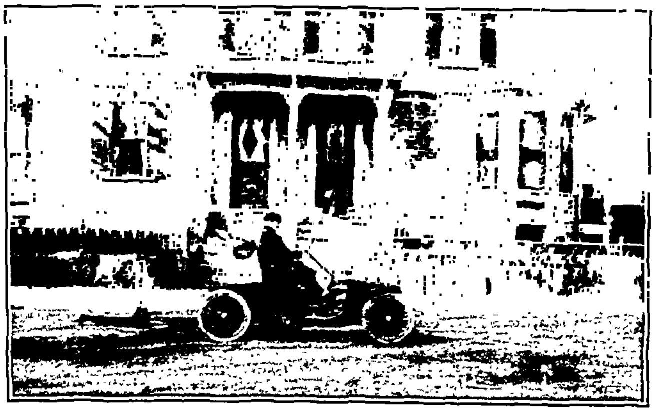

Fig. 19.—Dr. L. G. Beeley, Lawrence, Mass., in his second machine (133) described in his article.

L. G. Beeley, M.D., Lawrence, Mass.

A CLUB OF PHYSICIAN AUTOMOBILISTS

THE PHYSICIANS' MOTOR CLUB OF PHILADELPHIA

PERHAPS the first organization of its kind in the country is the Physicians' Motor Club of Philadelphia, in whose organization I had an active part. I happen to be one of the two original physician motorists (172) of Philadelphia, having been through the process of evolution of the automobile since 1898, during which year I organized the Pennsylvania Automobile Club and conducted the first regular run ever held between Philadelphia and Atlantic City. At that time the participants numbered fourteen, almost the entire motoring community of Philadelphia and vicinity. Dr. J. Sylvester Deehan has been my co-worker since the inception of the organization, six months ago.

The purposes of the club are as follows: It seeks to influence sane legislation for automobilists in general and physicians in particular. The club has no desire to seek undue privileges for the members as drivers but to have privileges which should be extended to medical men when in the performance of their duty to the community. In many states, of which Pennsylvania is one, it is only by police indulgence that the fire-engine has the right of way to save property, and the patrol ambulance the right of way to save life. Now the sum of emergency work done by practicing physicians in a city in twenty-four hours is far in excess of the emergency work done by ambulances in the same city during the same time. Of what service is the ambulance which rushes to pick up a patient to transport him to a hospital when the medical or surgical chief, on his way to administer the real service to the patient, is held up by an officer at a number of intersecting streets to allow a coal-cart or an ash-cart to pass? It is the intention of the Physicians' Motor Club of Philadelphia to have each member of the organization carry insignia on his car only when in use by the physician and to remove it or turn it at all other times. Each doctor is pledged not to exceed the legal speed limit when in the usual performance of his daily routine work. Each member of the club is to act as a committee of one to report a member who might be guilty of a constant infraction of the present law. When a name is handed in by a club member or when a member is repeatedly brought to the attention of the police department, he is requested to appear before the committee on law and ordinance who have the disposition of his case. By these stringent regulations, it is evident that any tendency to speed mania will soon succumb to active treatment.

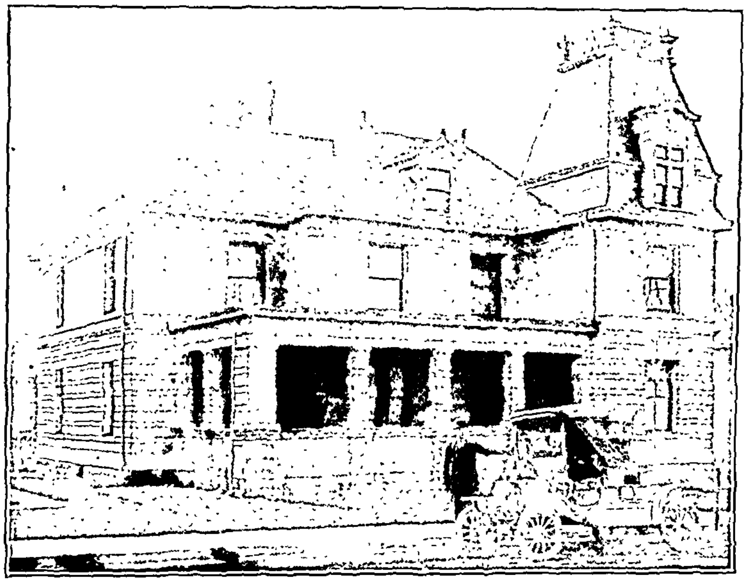

Fig. 20.—Dr. F. O. Wright, Wilmington, Ohio, and his machine (158), with his house and office in the background.

There is a time-honored custom giving the doctor the courtesy of the road, and it is the firm belief of this organization that after there has been a sufficient demonstration of good faith on the part of the members, this custom may be made a law.

The social side of the club is also taken care of and runs are being arranged for during the coming season. These runs will have the effect of letting the men get acquainted with each other and with their machines. Many medical men have the desire to enjoy the country with its relaxing influence but are timid about venturing out alone—a characteristic of all medical men.

The commercial problem is being taken care of and each member has an opportunity afforded him to learn to run a car on an economical basis if he is the driver; or if he employs a chauffeur, he can buy supplies without the help of this "trusty."

Lectures are given by mechanical men from time to time on the "A B C" of the motor car. The etiology, clinical course and treatment of all acute motor and gear diseases are discussed. The preventive treatment of mechanical and tire troubles are thrashed out; and in every way the member is placed in a position which makes him master of the motor car which has become part of his business outfit.

The club, as an organization, takes no part in the buying of supplies or sundries, but arrangements have been perfected by which a member can buy all the necessaries for a motor car at the regular wholesale figure. He is also taken care of when purchasing a new car.

It is the purpose of the club to encourage the formation of similar organizations throughout the country with the ultimate purpose of an affiliation of the separate club; for "in union there is strength." A series of horn signals to be used by moving motor vehicles is being compiled, the purpose being to have them used in a manner similar to those used by vessels, in this way giving notice to pedestrians and to other vehicles, which will minimize the number of accidents and prevent many collisions.

S. LEON GANS, M.D., Philadelphia.

A LIGHT MACHINE WITH PLENTY OF POWER

FROM my experience I find a light machine with lots of power is what is needed. I have bought a 20 horse-power car (208) with pneumatic tires; it has 4 cylinders and weighs 1,100 pounds. The main objection to the solid-tire machine is the slowness. A busy man cannot spare the time which the solid-tire car requires; and a pneumatic will go when any machine ought to go. I find that my car does not consume half as much gasoline and oil as did the other machine. My work is all in the country and I find it more convenient and profitable to hire a team when the automobile cannot make the trip. I would advise a prospective buyer to get a good machine, the best his pocketbook will allow. I made a mistake in getting the high wheeler and cannot recommend it for a physician's use.

C. O. NELMS, M.D., Herscher, Ill.

THE MOTOR CAR BOTH A LUXURY AND A NECESSITY

MY MACHINE (158), purchased last April, has been both a luxury and a necessity. It can easily do the work of three horses, and its use has enabled me to take pleasure trips that would have otherwise been impossible. Comparisons are no longer odious, given a good machine, the owner familiar with its mechanism, and willing to soil his hands occasionally, to make needed adjustments and repairs. Any one who listens to the agent's story that his particular machine is "fool-proof" will be sorely disappointed.

The physician's machine should have 32 by 3½ inch wheels, base 100 inches, water-cooled four-cylinder *en bloc*, not less than 20 horse-power with the elimination of all unnecessary weight. Avoidance of "speed-mania" will add years to the life of the machine.

F. O. WRIGHT, M.D., Wilmington, O.

AUTOS IN EVERY PART OF THE COUNTRY

AUTOMOBILES IN WYOMING

FROM 1902 to 1906 I practiced medicine in the Carolinas. On account of the nature of the territory, I confined myself entirely to horses, for automobiles had not then reached their present stage of efficiency. Even now, I doubt whether a machine would be practicable there. Certainly it could not be used exclusively, for off from the few main thoroughfares that have been macadamized, the frequent rains combine with the red clay soil to form a sticky mud, hub-deep for a third of the year.

Early in 1907 I sought health for my family in the "golden west." We traveled for some months in several of the Western states, but chiefly in Colorado. In that state we used an automobile to a considerable extent, and found the roads excellent, and an automobile entirely satisfactory.

In Wyoming we found climatic conditions ideal for our purposes. I found a suitable location in Wheatland, a town of 1,500, the center of a large territory. The radius of my practice is about a hundred miles, so that the question of a method of transportation quickly became paramount. In the early part of 1908 I was using six horses to do my work. It was then that I decided to try an automobile.

My knowledge of automobiles was exceedingly limited, but I have a liking for mechanics and some skill along that line. In Denver I purchased a car which a chauffeur ran with me through the country to Wheatland, but even his skill could not hide its two main defects, lack of road clearance and deficient horse-power.

For the summer I disposed of my horses and during that time my troubles were legion. I cannot remember that I ever ran my machine for one whole week without having enough trouble to last a man six months. Presently I was forced to purchase two horses, as my livery bills were enormous. I used the machine about town and on selected trips, when it seemed to be in the notion of running (I say "notion," for that auto appeared as animate and perverse as a balky horse). Something was always going wrong, and the machine has cost me $50 a month since I have used it. During the winter I have abandoned it entirely, going back to horses, and have been more comfortable in my mind if not in body. I have not given up using an automobile, however, for since making a thorough investigation, I have decided that hitherto I have owned a junk wagon and not an automobile.

I recently purchased in Denver a four-cylinder, 35 horse-power car (137), equipped with roadster body; and I am satisfied that this one will do what the other one did not. Still, in this territory there are certain trips that it is useless to undertake with the auto. Very often the road for 50 miles will be admirable, and then one comes to an unbridged stream, a gulch or a sand-draw that is impassable, and the nearest ranch-house may be from 10 to 30 miles away. In this connection, let me say that I would not recommend an automobile to any man in this country who was not himself something of a mechanic. Often, my troubles have occurred when I was twenty miles from help, and I would have been in an embarrassing predicament, could I not have done my own repairing.

I do not see that a machine has greatly increased my income or that it is in itself much of a saving. At least two horses are a necessity all the time, and during the three bitterest winter months horses alone can be depended on. Still, during the summer, it saves the busy man much valuable time, and one machine can do the work of six horses. Moreover, in this country, where help is scarce, the busy physician is saved time in his farmyard as well as on the road. Where a hostler is not to be had it takes a good deal of one man's time to look after six horses and their road equipment. Also it is a satisfaction to patients as well as to oneself to have the doctor within easy reach in case of emergency. The rest and relaxation, too, in driving a machine, is not a factor to be despised by a busy man. Nothing so quickly brushes from your mind the worry of your cases as the ribbon of road before you and the rush of wind in your face.

For a year my machine was the only one in town, but now there are twelve. Of these, only four have stood the test of our rather peculiar conditions: three 35 horse-power cars (138) and one 45 horse-power (139). The high-wheeled machines have not proved themselves here, nor has anything except a low-wheeled gasoline car. From my experience I would advise a medium-priced, medium-weight roadster, with particular attention given to road-clearance and hill-climbing ability, and with power enough to plow through deep sand and face the heavy winds of our breezy springs.

F. W. PHIFER, M.D., Wheatland, Wyo.

THE AUTOMOBILE IN THE MOUNTAINS

BEFORE deciding what kind of a motor car he is going to buy, the physician should take into consideration the condition of the roads in his neighborhood and whether he intends to use the machine all the year round or only during good weather. I have had five years of experience with the automobile and so far as I know am the only physician in central West Virginia who uses one in his practice. Our roads in this part of the state are very poor, even at their best, and during the winter months they got almost impassible for all wheeled vehicles. Until last September I used a low-wheeled runabout (183) which made good only during the summer season. I had much trouble with the pneumatic tire.

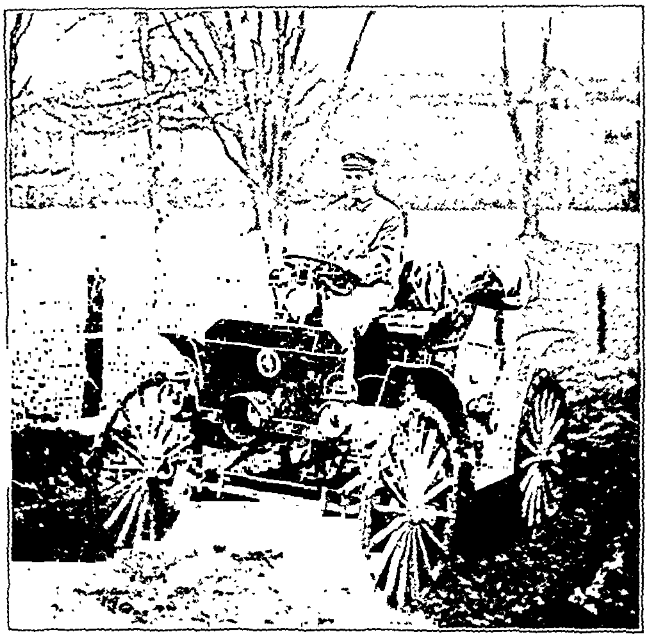

Fig. 21.—Dr. Beer climbing a "stiff" grade through West Virginia mud in his motor buggy (184).

The first of last September I bought a 20-horse-power friction-drive motor-buggy (184), which has 74-inch wheel-base and 38-inch wheels shod with 1⅜ solid tires, and is solidly built throughout. It has given me good satisfaction. I have run it every day since that time and it has not failed to go over the roads, no matter how steep the hills nor how deep the mud or snow. My expense has been about 3 cents per mile, counting everything. In my opinion there is no automobile made that can beat a good motor buggy for all-the-year-round hard usage such as vehicles receive in this part of the country. My machine rides as easy or easier than any low-wheeled pneumatic. It makes some noise, it is true, but that is nothing compared with the noise made by the owner of a pneumatic when he has a puncture some dark rainy night on a muddy road with a case of renal colic waiting at the other end of the road.

OSCAR B. BEER, M.D., Buckhannon, W. Va.

age amounting perhaps to one-sixth or one-eighth of that covered by the car this past year. Using a car strictly for business, I am sure that the cost of up-keep could be reduced by two-thirds, since the cost per month for the past four months, when no touring has been done, is $4.

The total cost per mile during the life of the car I have estimated at seven or eight cents: this includes first cost and up-keep; a rather high figure at first thought; it is not a difficult thing, however, to establish the fact that a horse in most cases will exceed this, taking into account first cost and maintenance.

From the standpoint of economy, therefore, the argument is decidedly against the horse, and I should regret very much to go back to that agent. Aside from the economy in dollars and cents, the wear and tear physically and time saved are not unimportant considerations; a night-visit is no longer a nightmare.

THE BEST MEANS OF RECREATION

To those to whom the automobile appeals, nothing surpasses it as a means of pleasure and recreation; there is a fascination in driving a car; one forgets cares and worries; it affords opportunity to explore new roads, enjoy new scenes, and experience a variety of pleasures, and if difficulties are met and emergencies arise now and then, they merely serve as part of one's motor education.

During the summer months the week always found us planning a trip for Sunday afternoon, and during the vacation period we went for all-day drives on Sunday, eating our lunch by the roadside, under the shade of a tree, unconscious of the existence of doorbell or telephone. Longer trips took us into other states; the most enjoyable one was through central Kentucky, where we visited Frankfort, Lexington, Georgetown and Paris, driving over the most delightful roads in the world, made of rolled stone and in many instances oiled for miles.

CLEANING CAR WITH WASTE INSTEAD OF WASHING

I have cared for my car for the most part myself. The sooner the owner acquaints himself with the mechanism of his car, the more certainly will he be able quickly to diagnose troubles, which is often necessarily done by process of exclusion. He should therefore keep in mind the most frequent sources of trouble. The necessity of frequently washing the car may be obviated by using waste, saturated with kerosene, being careful not to mar the paint; I know of one man who always has a clean, neat-looking car which has been washed but once in two years.

My car at first was not equipped with a magneto. I soon found the necessity of installing one, at a total cost of $62 (this is included in equipment, not up-keep). Most 1910 cars are equipped with this important adjunct; it is a *sine qua non*, and eliminates one of the most frequent sources of trouble. Late models are also equipped with improved oiling devices controlling the oil supply, thus obviating trouble from this source. The best remedy for carbonized motor is to close the valves on the two front cylinders, and when cool, to fill through priming-cups or plug-caps, with wood alcohol; then to close cups, and after four hours draw off with a grease gun, which has a slightly curved nozzle, and in the same way to fill the back cylinders, using the same alcohol, allowing motor to run idle after drawing off.

On one occasion, when I was at least one hundred miles from home, my motor began to knock when on level, in which case I used four ounces of wood alcohol in each cylinder, turned the crank over a few times, and after three-quarters of an hour proceeded. Whisky would answer and could be procured from most farmhouses. A small leak in the radiator may be temporarily stopped with a handful of corn-meal or flax-seed meal. The cylinders should be primed only with gasoline. The better way to start the motor in cold weather is to pour a tea-kettle of boiling water over the carburetor and intake-pipe. The most satisfactory oil (145) sells at 41 cents a gallon. Thirty by 3 tire chains may be made at home at a cost of $3.75, and require 23 feet of galvanized triumph chain, and 20 feet No. 3 German coil chain, six dozen "S" links, and four wire snaps.

THE CAR TO BUY

In purchasing a car give preference to four-cylinder motor 32-inch wheel, long wheel-base, sliding gear transmission and cone clutch. By all means specify a magneto, high tension type which eliminates vibrating coils. See also that there is improved oiling device.

There are one and two cylinder low-priced cars on the market which give fairly good service in good weather and on good roads. It is better to pay a little more, however, and get a car with more power than is actually needed. At $750 there are two cars in particular which I have in mind (146 and 147), which for every-day runabouts answer all practical requirements. Up to $1,050 one may have choice of a variety of cars which will give satisfactory service, and outclass the $3,000 car of six years ago.

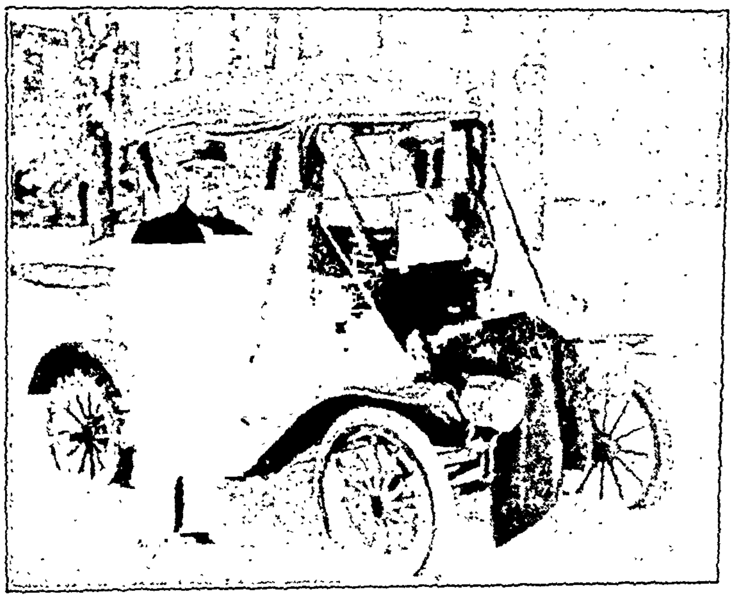

Fig. 25.—A winter scene in Indiana. Compare this with the picture on the opposite page. This car (144) is driven by Dr. C. R. Bird, Greensburg, Ind.

Automobiles now are well standardized, and improvements are largely in refinements rather than in principle. Some one has said, "But, after all else has been said, one significant fact towers above all others—that at no time in the history of this wonderful industry has there been so much similarity between cars regardless of the price."

Eternal vigilance is the price of an ever-ready, perfect-running car.

Charles R. Bird, M. D.,
Greensburg, Ind.

SIX YEARS' PRACTICE IN A LIGHT CAR

Just how long an automobile will last under careful driving and proper handling has yet to be determined, for the worn-out parts can be replaced like the parts of a jackknife as they give way and one can go right on using the original form indefinitely if one so chooses. After a certain time, however, the machine will be in the shop more than usual from old age, and parts will become crystalized and dangerous to use.

HOW LONG WILL IT LAST?

The life of an automobile is largely determined by the power of its engine. An engine of power too high for the machinery is like a hypertrophic heart: it cuts short the life of its carrier. The speed craze on the part of the driver, if indulged on our American roads, will in a very short time wreck the best of cars. Nothing can be more disgusting than to see a physician afflicted with the speed craze. A good test for sanity would be this: Do you enjoy riding in an automobile faster or slower than twenty miles an hour?

UP-KEEP OF HEAVY VERSUS LIGHT CAR

As to cost of up-keep, no one with experience in running cars will doubt for a moment, I think, the advantage of the light car over the heavy one. Tires still continue to be the chief item of expense, and a heavy automobile will wear out its heavy tire long before a light car will wear out its light tire, and there is the extra cost of replacing the heavier tire besides. A physician does not need a heavy car for his work. If he wants it for other purposes, well and good.

In the summer of 1903 I purchased a curve-dash one-cylinder runabout (181) and used it constantly in my practice for six years. Last summer I sold the car and purchased a two-cylinder runabout (182), largely because my first one was out of style. My present car is rated at 12 horse-power and weighs about 1,200 pounds. It is somewhat heavier now, for I have had a canopy top put on it. This top changes the appearance of the car from that seen in the illustration to an automobile of the heavy type. The wind curtain in front protects me from the cutting breeze and side and back curtains with their celluloid windows will give a coupé effect and warm quarters. My engine drives the added top against our heaviest winds easily enough. I run my car now very much like an electric, which I consider the ideal pace for an automobile.

A large item in expense is saved by the owner diagnosing himself any trouble his car may have and requiring of the mechanic simply his time for the treatment. Any one who has a mechanical turn of mind will enjoy overlooking his car for any trouble that may be impending, and he will do this often; and he will enjoy driving his own car as well. He is not covered with the germs or odors of the horse when he uses an automobile in his practice.

EXPENSE LESS THAN BOARD OF HORSE

I kept an accurate account of my expenses for six years and found when I kept my car at home they were, all told, less than the mere board of a single horse in the livery stable, while the car would do the work of two horses. The day of the automobile for physicians is at hand and his car is the light one.

M. W. Ward, M.D.,
Woodland, Cal.

Fig. 26.—Winter scene in the Sacramento valley. Compare this, with the picture on the opposite page. Dr. and Mrs. M. W. Ward ready to start from their garage, Woodland, Cal. (Auto 182.)

THE BETTER WAY

Whether a physician finds an automobile preferable to a horse seems no longer debatable. Changed conditions incident to the practice of medicine make it impracticable to try to do the work of a large practice without a machine. The older physician who would care for the second generation of patients finds them living so far from the parental roof that an automobile is indispensable. The young physician requires all the time available to keep pace with the progress of his art.

SAVES TIME AND HOLDS PATIENTS

The ability to hold patients who otherwise would have to be relinquished, the gain in availability to the patient at his home and punctuality in the observance of office hours are elements that cannot be computed. "The time on the street" represents the doctor's lost hours. It is reasonable to estimate that for the man who travels over a considerable territory the automobile saves three hours daily. And one medical man facetiously observes that we waste half of this time talking over the relative merits of our machines.

In addition to saving time and so increasing a doctor's earning power, the automobile has proved a boon to the medical man along other lines; the greater protection it affords from exposure, exhilaration in driving, and last but by no means least a hobby for his idle moments.

SELECTING A MACHINE

The selection of a machine is much simplified by considering the two possibilities. The product of a firm with a complete plant for producing all of the essential parts of an automobile, and having them perfectly standardized; or the product of a plant which is in reality an assembling depot for the parts secured from many makers who have thus no personal responsibility in the completed product.

Almost any machine will give the worth of the price paid; some will give a great deal more for the money invested. The poorest automobile of to-day is better than the best of a few years ago.

FACTORS LESSENING UP-KEEP

The expense of maintenance is largely a question of the driver and the caretaker. The private garage will greatly reduce the items. A few of the factors in lessening the up-keep are:

A good equipment.

A clean machine.

Good oil constantly where it should be.

Periodical search for needed repairs.

Prompt repairs.

Tires of ample size and properly inflated at all times. Power and speed suited to the work being done.

Buying supplies at the right prices, preferably in large quantities.

Avoidance of grand-stand starts and stops.

Remembering that short turns and curbstones shorten the life of the tires.

A private garage.

USE AND REPAIRS

During the past year I have driven my 30 horse-power car (108) 7,132 miles with only one puncture, one from a nail which plugged the hole so that I was able to drive home. My tires have averaged about 5,000 miles. The spark plugs have never been removed. No work has been done on the engine except to renew some of the hose on the cooling system.

A trip to Maine and back, via the White Mountains, without trouble with any part of the machine, demonstrated the possibility of service and pleasure to be had from an automobile

My expense item has included the following items:

Gasoline	$79.74
Oil	5.29
Grease	3.70
Parts	2.94
Recharging storage batteries	3.00

B. Franklin Stahl, M.D., Philadelphia.

THE COST DEPENDS ON THE OWNER

My earliest experience with horseless vehicles was with a tiny curved-dash, one-cylinder runabout (150), which, according to its makers, "cranks from the seat, is seen wherever you go and goes wherever you see them." Two years' use of this machine was expensive, if calculated on a basis of mileage traveled, and in a way justified the remark of a critic that "it cost one dollar for each mile you see it going." That was, however, a criticism not taken too seriously, for those were pioneer days in autoing; one must learn auto mechanism sooner or later, and it was no doubt better and cheaper to learn on the small car.

My next venture was a 4-cylinder *air-cooled* physician's runabout (151). In 1904 this car was reckoned a powerful, reliable, noiseless and handsome professional carriage. I ran it every day, winter and summer, for nearly five years, mostly over the well-paved level streets of the city. It is still in daily use, runs better, I believe, than when new, and should, with proper care, prove an efficient city runabout for another five or more years.

I have recently acquired another car (152) which I selected because this particular type of car appealed to me most in points of moderate weight, apparent perfection of construction, and because of the guaranty of the makers.

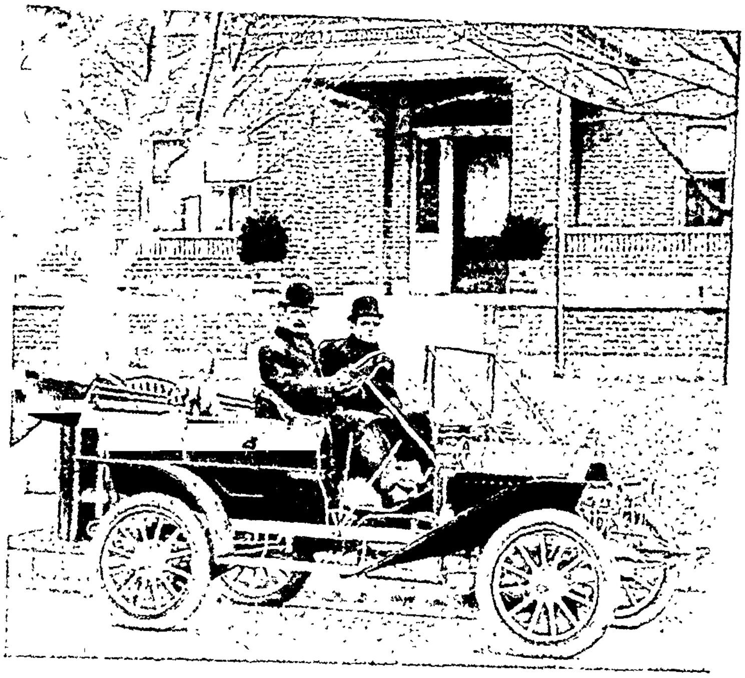

Fig. 27.—Dr. John F. Barnhill, Indianapolis, in his car (152), with Dr. Paul B. Coble, in front of Dr. Barnhill's residence.

But what interests physicians most, perhaps, is the truth about the cost of maintenance and operation of self-propelled vehicles. I have already stated that my first experience was expensive beyond reason, largely, no doubt, because I knew nothing of auto mechanism and because the earliest autos were experimental. The five years' operation of the second car was at an expense, excluding gasoline, oil, and tires, but including an annual painting, of not to exceed $500. During this same time oil, gasoline and tire replacement cost $650. The car itself cost $1,425, making a total of $2,575 expended in five years. Counting the old car still worth $300, this makes a total average expenditure for auto transportation of $455 per year.

In cost of auto maintenance there are two classes of owners who give widely different figures:

1. The one whose outlay is unreasonable and prohibitive. Such an owner, it will usually be found, has been a victim of the following errors: (a) buying a car without reference to the use to which it will commonly be put, in other words the use of a runabout for too much touring, or a touring car when runabout use is chiefly desired; (b) carelessness as to proper tire inflation, lubrication and use of anti-freeze solutions; (c) the owner's employment of a cheap and worthless chauffeur instead of driving the machine himself; (d) reckless driving, especially over roads never intended for an auto; (e) going to the repair shop for the nine-out-of-ten disorders which every owner should be capable of quickly adjusting himself.

2. The owner who is satisfied that the automobile is an economical proposition. Such an owner (a) has selected a car to meet the particular requirements to which he will put it, as well as one suitable to the environment as to the roads and hills; (b) drives the car himself, and with reasonable care, knowing that abuse and lack of proper attention to the machine are expensive faults; (c) studies auto mechanism to the end that he can diagnose his auto trouble at once and thus be able to correct the numerous little "tricks" which even the best cars play, and thus avoids the expensive repair man, except when some actual break of part has occurred; (d) uses the best and most suitable grades of oil and gasoline, and the best obtainable system of ignition, to the end that carbon in the engine is avoided, and the greatest possible amount of power and mileage may be obtained from the fuel consumed.

Any owner can, obviously, make either an expensive luxury of his automobile, or he can, if economy of operation is necessary or desirable on his part, cut the expense to a point that auto transportation becomes the cheapest available means of travel. But aside from cost, the pleasure derived from the rapid dash from place to place in a business way, or the invigorating spin to the country with one's family or friends after business hours, must be counted well worth while, even if the cost at times seems a little more than that paid by our grandfathers for the ox-team journey, or by ourselves a decade ago, behind a team of thoroughbreds.

I might also add to the above that I have maintained, for family use, a coupé electric car (153) for the past fifteen months. I keep this in my own garage, and charge from my own outfit installed for that purpose, and the expense of maintenance so far has not seemed unreasonable; and yet, when compared mile for mile with the gasoline machine my experience is that the electric costs twice as much as the gasoline conveyance. John F. Barnhill, M.D., Indianapolis.

MODERNIZING A 1908 AUTOMOBILE

Every mother admires her own babe most. Every automobile maker brands his product "best." Every auto owner thinks *his* particular machine is really "it." But we must admit that "there are others." There is no sense in my saying, just because I own a runabout (187) which I think is absolutely "O. K.," that it is the best machine in the market to-day. I realize that there are others just as good.

THE LIGHTING SYSTEM AND THE BATTERIES

But what concerns me just now has to do with this car. When I bought my machine in July, 1908, it was furnished with few accessories. I set about at once to put on the things that I liked best. Beginning with the lighting system, a headlight (188) was installed on a pivot bracket on the inner side of the dashboard so that I was able to swing the light around a corner, or up against a street sign. Many a night it has come in handy when looking for a particular house number. This headlight burns gas furnished in tanks (189). The side and tail oil lamps were exchanged for electric lamps run in connection with the storage battery. But one night I forgot to turn off the battery supplying the lights, and when I came out from seeing a patient there was not enough life in the battery to get me home; hence the change back to oil lamps.

Every one knows what troubles are caused by weak batteries. So disgusted was I that I took out the battery and the dry-cells and put on a magneto (196). Since that time (July last) I have been entirely free from battery troubles. The machine starts on a quarter turn of the crank, and furnishes a strong rich spark.

THE TOOL-BOX, TRIMMINGS, ETC.

Those readers of this article who own machines like mine know what an ugly tool-box is provided. Mine soon warped and allowed the tools to get wet every time it rained. Since it occupied plenty of space I saw the possibilities. A carpenter made me a box sufficiently long and wide, put on top irons and placed it on the rear. Now, thank you, I have a rumble seat for a third passenger and a dry place for tools.

I never could understand why there is so much brass on autos. Nothing is so dirty as dirty brass. Rather than have a porter stand over it all the time, I had it all painted black. I have not regretted the change.

I have found that "spring-washers" will keep a bolt tight when nothing else will; that heavy grease in the differential will keep the rear wheels clean from spattering oil, because it does not liquefy like thin grease; that an extra inner tube and casing saves much irritation; that a priming cup on each cylinder-head will allow me to put gasoline directly into the cylinders to make the machine start more easily on cold days; that a few drops of kerosene oil dropped into each priming-cup will keep the cylinders clean; that one-third each of glycerin, wood alcohol and water stopped all freeze-ups, and that an extra two quarts of oil and gasoline, and an extra magneto belt and an oiler belt are most indispensable when I least think of them.

SERVICE AND EXPENSE

It is truly remarkable what punishment these small machines take and stand up well under it all. I went to Milwaukee from Evanston one Saturday forenoon, a distance of 90 miles, in six and one-half hours, on three gallons of gasoline. I have run the machine almost every day for eighteen months in all kinds of weather, and over all kinds of roads. It has carried me over 10,000 miles. The only thing that broke was a fender-iron, and that was replaced at a blacksmith shop for 75 cents.

It may be of interest to know what has been the expense to me since I bought it eighteen months ago. Well, in the first place, I keep the car in my own garage. It is 12 by 18 feet and 10 feet high, 2 by 4 uprights with 2 by 6 rafters. This is covered with corrugated sheet metal, painted and a sliding door hung on the alley side. The floor is of ashes. Since the item of garage expense is cut off, and since I buy my oil and gasoline at wholesale, you see that I am ahead of the game at the start. My whole automobile expense per month is $19.32.

I am in favor of the small runabout car for city use, because while allowing the maximum speed permitted, its up-keep expense is the minimum. Why drive a four-horse team about when a single horse will well do the work? I have found that a small car uses far less gasoline and oil and is the lightest on its tires. These three items being small, the cost of running the car is correspondingly small. I have added to the equipment as follows: wind-shield, top, rumble seat-tool box, magneto, carburetor (190) (haven't had to adjust it since it was put on in July, 1909), headlight (188), bigger gasoline tank, holding twelve gallons under the seat, small trap-door on top of the hood to allow immediate access to the priming cups, and a meter (191) to measure the miles.

Taken all in all, I venture to say that I have a car that compares well with many a larger and more expensive car from the standpoints of usage, expense and convenience.

As to using a horse, I would not ride behind one except to a funeral. John A. Kappelman, M.D., Evanston, Ill.

TROUT STREAMS AND HUNTING GROUNDS BROUGHT WITHIN AN HOUR OF THE CITY

Until a year ago—that is for twenty years—I have driven horses. Then I sold my rig and bought a touring car (148). I would not return to the horse. A machine is cheaper to maintain, can be left without hitching, does not get frightened, is under perfect control, does not get sick and does not have to be exercised when not wanted for use. It is warmer in cold weather and vice versa. A greater extent of territory can be covered by the machine and, to me the greatest desideratum is, that one can get out of the city in an hour to the country, trout streams and hunting grounds, and enjoy a few hours of unalloyed bliss, or with his family ride over new routes and enjoy new scenes.

I take entire care of my car. I have taken it all to pieces and put it together again, and it runs perfectly. An automobilist should know his car as a driver does his horse. Some people never learn to drive a horse properly and some people can never learn a machine perfectly, those are the kickers.

As to expense, I am $25 to the good over the horse for one year and I have had many times the enjoyment and mileage. A. S. Bolster, M.D., Worcester, Mass.

TAKE CARE OF YOUR AUTOMOBILE

If you have owned and operated your own car for seven or eight years don't read this little article, for you know as much about it as I do. It is for the benefit of those who are new at it that I am writing these few words. One of my greatest enjoyments in motoring is in taking care of my own car (121), so I say, if you can possibly find the time, take care of your own machine. You will find it a pleasure and an economy at the same time. No matter how trustworthy he is, the other fellow is sure to be more lax than you yourself; he will throw away the extra gasoline rather than save it to be used for cleansing, or what not, he will throw the hood open with a bang instead of laying it back, and so forth.

Briefly, my advice is as follows: When you come in from a run, or at the end of the day, wipe off the body with some waste; this will do the varnish a world of good where frequent washing will do just as much harm. Open the hood and clean the inevitable grease, dust and dirt from the engine, fan, carburetor and piping. By doing this the power plant always looks neat and you will not ruin a clean shirt or coat in trying to make a hasty adjustment that may be necessary when starting or when on the road. Fill your water, oil and gas tanks, thus avoiding irritating, exasperating delays on the road which can only be charged to your own carelessness. See that the grease cups are filled, and where these are not provided put a few drops of oil, looking, meanwhile, for any loose nuts or bolts. Your machine can run without these, but you don't want it to do so. Frequently, and I believe once a month is none too often, jack the car up and examine all four wheels for loose bearings. By doing this you may avoid large repair bills and enforced idleness for your car while a new set of bearings or even a new axle is being installed. Keep your tires hard. You will get more speed and more mileage for your trouble. These things attended to, your car is ready for starting at a moment's notice, at any time of day or night.

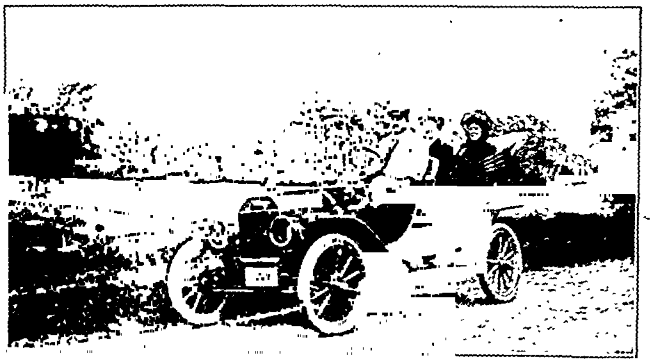

Fig. 28.—A country pleasure ride in a touring car (148) driven by Dr. A. S. Bolster, Worcester, Mass.

When on the road, follow the golden rule, "Do unto your car as you would have your car do by your pocketbook." Feel for the machine; it cannot feel for itself. Use common sense when starting and stopping, doing both gradually. Nothing will do the transmission so much harm as overlooking this easily followed suggestion. Go as fast as you may care to ride on a straight smooth road, but slow down for the many thank-you-ma'ams which invest city crossings, or a broken spring may be the penalty. Do not turn a corner at twenty miles an hour when you can do so at ten, besides, the latter is better for you (mentally, morally and legally) and for the frame of the machine. To get best results open and close the throttle gradually.

To conclude: If the engine worries along on only three cylinders, fix it immediately yourself, for you can do it just as well as to pay a repairman sixty cents an hour to tinker for you, and too often that is his stock in trade. Use deduction, the Sherlock Holmes kind, and you can diagnose and successfully treat your case nine times out of ten.

T. Albert Peppard, Minneapolis.

OPERATION OF FOUR-CYCLE AND TWO-CYCLE ENGINES

The life and the energy of the gasoline automobile lie in the engine or motor, located beneath the hood in front of the dash and connected to the rear wheels by transmission gears, rods and chains. To build a motor for this purpose with a maximum of efficiency, durability and economy, with a minimum of mechanical detail, replacement and care has engrossed the attention and demanded the scrutiny and study of the world's engineers, and to this end, the four-cycle and two-cycle motors, varying considerably in their own individual arrangement, have been gradually developed and perfected.

ANALYSIS OF OPERATION

Within the cylinder of every gasoline engine four operations occur consecutively:

1. Intake of the charge.
2. Compression of the charge.
3. Explosion of the charge.
4. Removal of the burned gases or residue.

In the four-cycle type (Fig. 29, A) each of these operations is represented by a stroke of the piston. At the first or downward stroke, the vacuum produced draws the charge into the cylinder through the inlet valve, automatically opened at the time; following this the inlet valve closes and the piston returning, compresses the vaporized gasoline into approximately one-fourth the cylinder space. At the end of the second stroke explosion of the compressed gases takes place, and under the generated pressure the piston again descends, delivering the mechanical power. The exhaust valve, timed to open now, or at the beginning of the fourth and last stroke of the cycle, permits the emptying and cleansing of the cylinder during the entire ascent of the piston.

In the two-cycle motor, aspiration, compression, explosion and exhaust of the gases are obtained in only two strokes of the piston. This is made possible in that with every downward stroke a power impulse is given, and at the same time, through the piston's descent, precompression in the crank-case or in an annexed chamber established; while with every upward stroke, a fresh supply of gas from the carburetor is drawn into the crank-case and also compression of the charge within the cylinder accomplished. For this reason it is called the two-stroke-to-the-cycle engine, or for short the two-cycle engine.

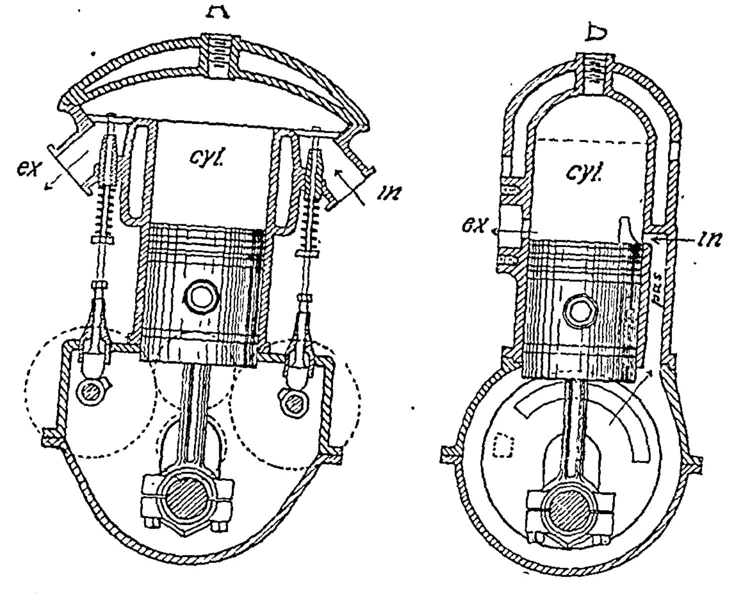

Fig. 29.—A, type of four-cycle construction; B, type of two-cycle construction. The details are explained in the article.

In Fig. 29, B, the cylinder, "cyl," is represented as filled with a fresh charge; on ascent of the piston compression and ignition follow which drives the piston toward the bottom of the cylinder, and the burned gases begin to make their escape through the exhaust port, "ex." A moment later the piston, descending to its lowest level, uncovers the inlet port, "in," and admits the compression charge from the by-pass "pas" and the crank-box. The inrushing and expanding charge completes the scavenging of the cylinder, but is deflected in such a manner as to allow little or no mixing of the gases.

It is claimed then for the two-cycle engine that it will perform the four operations in one-half the time occupied by the four-cycle, that it does this without the intervention of some fifteen to eighteen parts of valve-lifting mechanism to the cylinder, and that with double the impulses smoothness in operation together with 50 to 60 per cent. of additional power is obtained.

I drive a runabout (197) with a two-cycle engine and find it satisfactory.

James B. Baird, Jr., M.D., Atlanta, Ga.

IT'S WORTH THE DIFFERENCE

Regarding the use of the motor car by the physician my conclusions are based entirely on my own experience; that is, the experience of a country physician who is obliged in the course of a year to drive from 8,000 to 10,000 miles in a locality where good roads are the rule. I may state that my experience has been long and varied, for I have used a motor car since the early days of the automobile industry.

A PIONEER USER

I purchased my first car in 1899, and after more than ten years of constant use of motor cars in my business I am a firm believer in the automobile as a paying proposition for the country doctor. Does it cost more to operate and keep it in running order than it does one horse? It certainly does, but the comparison is unfair, the two are so entirely different.

SAVES MONEY BY SAVING TIME

A motor car will do the work of all the horses one man could find time to drive, and do it in one-half the time. If one's time is worth anything the motor car is certainly a great money-saver. Estimates of the comparative cost of keeping up autos and horses are often very inaccurate. We are too apt to base our opinion on the first year's use of the automobile, when repair and tire bills are generally small; if we do so the account will be favorable as compared with the expense of keeping horses. Repair bills will increase with the age of any car.

I am unable to state the actual cost of operating, repairing and depreciation in value of the various cars I have used in the past ten years. I once kept account of expenses for a short time, but it made me feel guilty. I felt as I would were I to keep account of the expense of being married. Supposing it does cost more to run the motor car than it does to drive horses: isn't it worth it? It permits you to spend more time at the office and catch an occasional stray dollar, that fracture case didn't go to some one else because you were not in—and it is such jolly fun to be bowling over the road on a hot, sultry day when you would feel sorry for the horses you were driving. All this is worth the difference in the expense.

HIS RECORD OF CARS

My first car was a steamer, one of the first ones sold by that concern (154), of narrow-gauge tread with a fire-tube boiler about as large as a good-sized teakettle. This little car would be considered a mere toy to-day; the burner had to be generated by a piece of bent gas-pipe heated in the kitchen stove; it reads like a joke now, but it wasn't in those days. It sometimes did run and it made more stir than any car I have owned since. It took a brave heart and a great deal of patience to go out on the road when every horse attempted to climb the nearest fence and every driver "cussed" that devil-wagon. My second car (155) was also a steamer and was quite an improvement over the first. My third car, a two-cylinder gasoline car (156), made the remarkable record of covering 52,000 miles in the six years of service. My present car (I never dreamed cars would be so perfect) is a four-cylinder 20-horse-power car (157) of the heavier type. It has covered 3,800 miles since August with virtually no trouble or expense, but next season there will probably be repair bills and new tires, but what of it? Were I obliged again to use horses in my business the year round I believe I would throw up my job.

E. Windmueller, M.D., Woodstock, Ill.

RELIABILITY THE DESIDERATUM IN AN AUTO

SOME years ago I became convinced of the necessity of overcoming distance with decreased time. Still, the horse was at least sure of arriving at the destination, while machines, I had noticed, were often passed by the wayside by that faithful animal. I therefore began to look for a machine that could be depended on to reach the desired goal which would not be too expensive or too complicated and which I could understand and run, if necessary, myself.

I found what I sought after some search, and, seeing the simplicity and apparent practicability of the machine (201), I ordered one, which I have used for eighteen months at an average cost of less than $14 a month for oils, repairs, etc., with an average mileage of about forty miles per day. The past winter, because of its severity and the condition of the roads for weeks at a time, demonstrated most practically the absolute dependence which I could place in the machine. I can heartily recommend my car as being very practical for physicians, on all conditions of roads and under all circumstances. J. LELAND BOOGHER, M.D., St. Louis.

THE ADVANTAGES AND DISADVANTAGES OF THE STEAM CAR

IN THE JOURNAL'S previous Automobile Numbers I have been surprised to find so little relative to the steam car, which seems to be giving good service in this section. After close observance of the types of cars, I purchased last summer a steam car (102) of 10 horse-power, which thus far has given me excellent satisfaction. One should, before purchasing any make of car, know the pro and con of the car.

TROUBLES

A troublesome feature of my make of car, which would apply to all steam cars, is the constant refilling of the water reservoir, under the seat, which has a capacity of thirty gallons, requiring for convenience, water and hose attachments, both in the garage and in front of the office and residence. A trip of ten to fifteen miles would consume about one-half the contents of the reservoir, depending of course on the condition of the roads and the number of hills encountered, thus making it unwise to attempt like trips without first having refilled the tank, so that for touring purposes I would not select a steam car, unless I was acquainted with conditions of water along the route. Granting the presence of watering troughs along public highways, much of the trouble would be averted, since there is hose and injector attachment, that one may easily refill the tank in a few minutes.

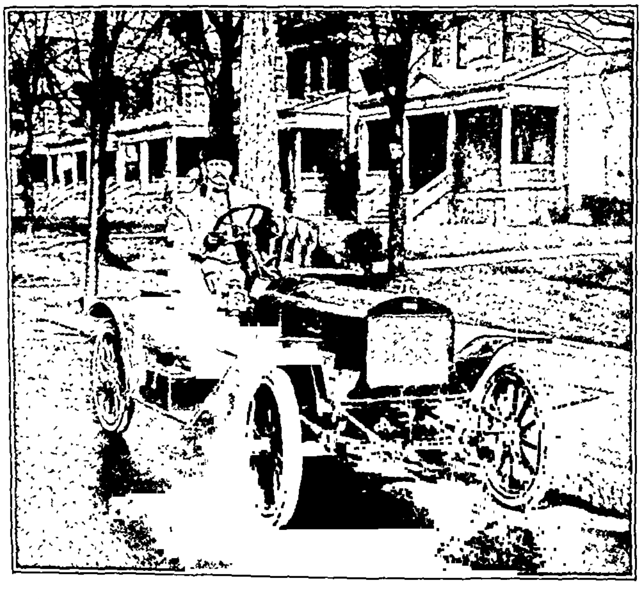

Fig. 30.—Dr. J. Leland Boogher, St. Louis, in his automobile (201).

STEAM VERSUS GASOLINE CARS

I believe one has more trouble with a steam car than with a gasoline car, but not of such nature as to detain one long on the road. The gasoline consumption of the steam car is greater than that of the gasoline car, averaging from 7 to 9 miles to the gallon of gasoline, according to the condition of the roads. The steam car should have a warm garage in winter, if it is to be used during pleasant weather, but I have yet to see the auto that will combat snow-drifts and hills such as we have here.

GOOD POINTS OF STEAM CAR

Having briefly enumerated the troubles of my car, I can say in its favor, for endurance, durability and simplicity, it is, I believe, without a peer. Trouble is quickly located. Easy access to all parts: no cranking, wires, dry cells, carburetors, magnetos and the like which trouble some, hours, nay, days as I have seen. My car is noiseless in stopping, starting and passing fractious horses, with little or no odor of gasoline, making as little vibration as possible, which, to my mind, is a big saving on tire wear. As to the time required in steaming up, will say that I can, if need be, obtain sufficient steam in ten minutes to leave the garage. I find that more practical instruction could be embodied in the company's instruction-book, which is very meager in many respects. They stand ready, however, to repair any defect in their machines, and give prompt attention to all.

A DEPENDABLE CAR

To the physician, who needs a good dependable car that will stand much rough usage for his business, and who can overlook the troublesome features mentioned, I can conscientiously recommend my type of car. I shall continue to use a steam car until I am convinced of the superiority of the gasoline car.

A. H. HILL, M.D., Mifflinburg, Pa.

COST—CYLINDERS—COOLING

ON PLANNING to purchase a piano or a watch or a static machine for long and satisfactory service, do you not go to a reliable dealer of long standing, who sells a make that has been tried and tested, that has been on the market for years, and that is recommended by those competent to judge? On the other hand, if collections are bad and you want a piano merely to fill a vacant space in your parlor, or a timepiece merely to attach to a fob, or a static machine to stand in your office for the psychic effect it may produce on your patients, a cheap product may answer your purpose.

HOW MUCH DO YOU WISH TO INVEST?

With these comparisons and illustrations in mind how much can you afford to put into a motor car? Can you spend $8,000 or $10,000? If so, buy an imported car and you will have one into which has been put the best material and construction obtainable.

If you can spend, say, from $2,000 to $5,000 for a car, there are numerous American manufacturers who have been staking their reputation on the output of their factories for half a score or more of years. Their product has been improved from year to year until at the present day a mere novice with a dozen or more makes to choose from, and with closed eyes, would make no serious blunder.

DISCRIMINATION REQUIRED IN BUYING CHEAP CARS

In selecting a car at a price varying from $800 to $1,500 more discrimination must be used. Many cheap cars are at present on the market, to which the time test has not been successfully applied. There has always been and probably always will be a demand for a low-priced car, but thinking men are being gradually convinced that with labor and material at its present price, it is practically impossible to construct a satisfactory car at less than $800 or $900. If a mere toy is wanted, simply to stand in front of the doctor's door, and to take an occasional spin on an asphalt street, there are manufacturers who will supply the demand. But touring in comfort, which is what the doctor really needs, is out of the question with such a car. Of course, in all cases, much depends on what use the car is to be put to and the personal equation of the driver.

CYLINDERS

When it comes to cylinders, men seem prone to buy them on the same principle that the patient "took his pills." If one pill was to do him good, two would do him more good, and finally he thought the problem solved by taking the whole box. At present *there are more four-cylinder cars in use than of all others put together.* The increase is notable in the last two years. They have been recruited largely from the two-cylinder class. The whole thing is summed up by how much horse-power you want your car to have. The greatest number of models at both the New York shows this year were from 25 to 35 horse-power. Cars of this horse-power should be of the four-cylinder type, but for a good common-sense car, developing from 16 to 20 horse-power and a speed of twenty miles per hour, two cylinders are enough. Experience seems to have proved that for medium power cars, say under 20 horse-power, the two-cylinder opposed is the most practical. The power furnished by an engine cylinder is in direct proportion to its cubical capacity. One cylinder with a bore of five inches and a stroke of five inches will develop 8 to 10 horse-power, while two cylinders of same dimensions will develop 16 to 20 horse-power. A four-cylinder engine with no greater combined cubical capacity will develop no greater power than the two-cylinder engine. A four-cylinder engine increases the number of parts needlessly, complicates the mechanism and increases the cost. What is the use of using four horses when two will answer the purpose? Four, and even six-cylinder engines undoubtedly have *their place;* for instance, where more than twenty horse-power is required, or where a car is intended for the transportation of five or more persons at a high rate of speed.

But from the standpoint of the average motorist, not the faddist, this same average motorist who is the mainstay of the American *automobile industry,* the 20 horse-power two-cylinder car has an advantage in simplicity of construction over its many-cylindered brother.

COOLING

There seems to be a variety of opinion among the exponents respectively, of the air-cooled and water-cooled motor. *It is a notable fact,* however, that of all gas engines used for practical purposes by far the *greater number* are water-cooled. It is also a notable fact that no great race has ever been won by an air-cooled car.

Water cooling is more reliable than air cooling under all climatic conditions. In an air-cooled motor the temperature varies with that of the atmosphere and the cylinders may, at times, become dangerously hot. To cool sufficiently with air the cylinders must be comparatively small. The motor, of necessity, works at a higher temperature. For this reason the valves do not remain tight and need frequent regrinding.

Among the water coolers, the question as between pump or *thermo-siphon* circulation seems to be no nearer a definite answer than last year, for the number who use each system is practically the same. *I am inclined to favor the* thermo-siphon system of cooling and believe that cars using this system will increase from year to year.

IGNITION—SHAFT DRIVE—BRAKES

Magnetos are well to the front. *On a large number of this* year's models both batteries and magnetos are to be found. Even on the cheapest cars magnetos are to be *found, there* being more models selling below $1,000 which have magnetos than there are that do not. There is no car at present selling for more than $3,000 that is not equipped with magnetos. There seems to be an increase in popularity this year of the *shaft-driven* car, and also of the double-brakes on the rear hubs.

David Edward Hoag, M.D., New York.

Surgeon for the Glidden Automobile Tours; Surgeon to the Brighton Beach Motor Racing Association.

AN ENJOYABLE AUTOMOBILE RIDE

For five years I have been using automobiles. I have used, for business and for pleasure, everything from a single-cylinder to a six-cylinder machine (105); but thinking that technical subjects will be well cared for by others I have chosen quite a different experience to describe.

The automobilists of the United States are organized much after the manner of the physicians. There are local clubs, state clubs and the Three As, which, as a national organization, corresponds to the A. M. A.

The A. A. A. designates a day early in the summer as Orphans' Day. The local clubs are expected to give as many orphans as possible an automobile ride and outing on that day. On the third of last June the Automobile Club of Cincinnati gave such an outing to 1,100 orphans, inmates of the various institutions of this city. The children were gathered from the various *institutions* and brought to the heart of the city, where *they were formed* into a parade, the children each being given a small flag and the automobiles were suitably decorated. As president of the Cincinnati Automobile Club it was my pleas*ure to lead this* parade, and I am sending a photograph of my car as it appeared.

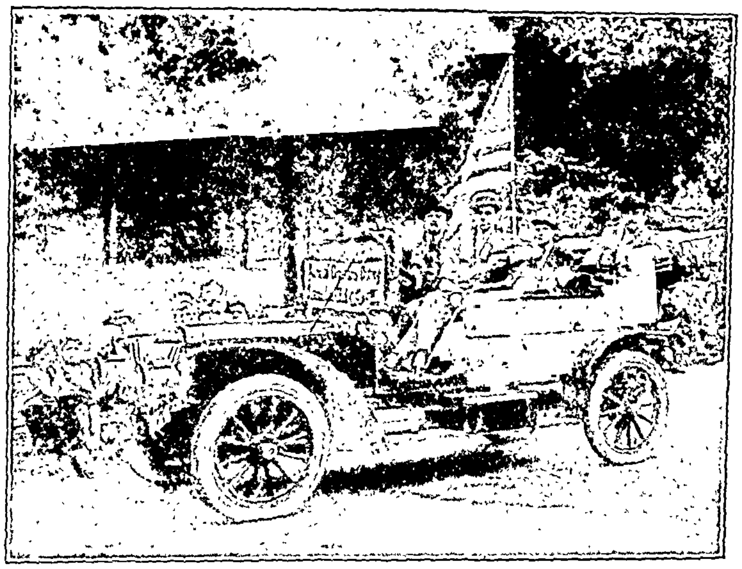

Fig. 31.—A physician cooperating in giving an outing to the orphans, an annual feature in many cities. Dr. Charles L. Bonifield, president of the Cincinnati Automobile Club is at the wheel. In the left rear seat is Mr. Rogers, superintendent of the parks of Cincinnati. (Auto 106.)

We passed through a number of the main streets of the city, then took them through the suburbs on the hill tops, stopping at Burnet Woods, one of the city parks, for a band concert. We then proceeded to Chester Park, an amusement resort, where *not* only the gates, but *all* amusements on the grounds were open to the children free of charge. It was a sight to be remembered, to see these homeless children, many of them crippled and deformed, enjoying these amusements so novel to them. They were each served with a substantial luncheon and at sundown delivered to their *institution* without a single accident having occurred to mar the pleasures of the day.

I urge every doctor who reads this and who owns an automobile to join his local club and be an active participant in the next Orphans' Day Outing.

C. L. Bonifield, M.D., Cincinnati.

THE AUTOMOBILE ADDS TO EFFICIENCY IF NOT TO INCOME

My father and I are associated and do a large general practice in a community of more than 400,000. The roads are fair for the middle West but there is much to overcome before they could be considered good. The country is very hilly and many of the roads and especially the streets are precipitous. We cover a radius of from four to ten miles, and together our mileage is about 15,000. A chauffeur is a necessity. We have three machines, two single-cylinder cars (198) and a larger one (199), all water-cooled. The large touring-car for the family is not included in these estimates. All cars are driven by gasoline and are equipped with extra large pneumatic tires. We have been driving machines for five years.

Previously we used horses. We always had four and sometimes six. Three buggies were required and $2,000 would probably cover investment in them. The three machines and their equipment may be conservatively estimated at $5,000. I have estimated the equine up-keep, including coachman, at $1,500, and that of the machines at $2,000.

In addition to the above expenses I estimate the depreciation of horse and buggy at 25 per cent. ($500), making total expenses $2,000, and that of the automobile 20 per cent. ($1,000), making that total $3,000. Very little of this expense or mileage is for pleasure. The income has at least increased sufficiently to care for the increased expense. Estimated in dollars and cents, I should say that there is greater expense, therefore greater risk, and no greater profits, and that therefore from a business standpoint machines may not pay. But their use adds so much to the doctor's efficiency, both with regard to better service to his patients and to time and opportunity to study and rest that machines more than pay. I should feel it almost retrogression if necessity required me to return to horses.

The choice of the car is one that requires much consideration. Such a choice demands adaptation to the requirements of the individual man. The cheapest car to maintain is undoubtedly the single-cylinder runabout. Our two of this variety (198) have been run for five years and are doing yeoman service over our very hilly country. They will go anywhere any other car will go, but not so comfortably or so swiftly as some. In our practice they have been maintained at about $20 per month each, exclusive of the chauffeur's wages and depreciation and a few extras. Such a car can be bought and thoroughly equipped for a little under $1,000 and weighs 1,600 pounds equipped. On the other hand, nothing has ever given me more physical comfort and satisfaction than my large water-cooled car (199) which weighs 2,450 pounds equipped. It has abundance of power and responds to the slightest touch of the throttle. Its up-keep, exclusive of depreciation and wages, is approximately $40 per month. Certainly, if one's practice will justify it, the latter is the greater satisfaction. On the other hand, in a level country with good roads the increased expense would be a good deal to pay for pleasure and satisfaction, because the increased efficiency alone would not justify the expenditure.

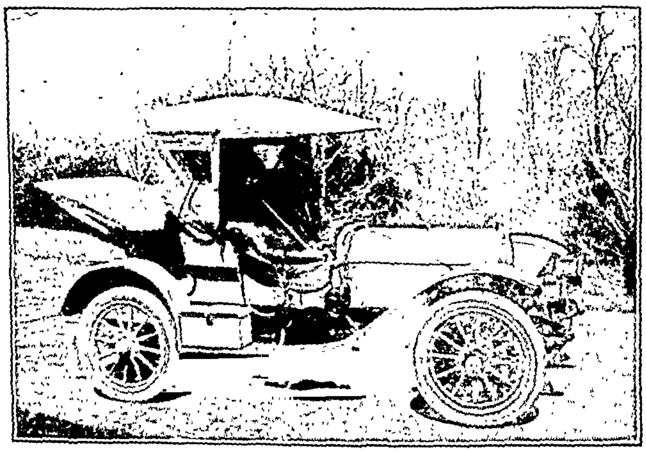

Fig. 32.—Automobile (199) described in accompanying article.

The greatest economy is effected by the use of large tires. I believe that each car should have one-third more tire capacity than the tire-makers require per wheel. One should always ascertain the weight of the car by running it on to good scales. Car manufacturers always underestimate weight. The large car (199), weighing 2,450 pounds, came equipped with 34 by 3½ tires. These are rated to carry 600 pounds per wheel, without load. Thus the four tires would be sufficient to carry 2,400 pounds. So equipped the tire was all shot to pieces in 1,500 miles. I changed my rims to carry 34 by 4½ tires. These are rated to carry 900 pounds per tire or 3,600 pounds. Since this change I have averaged much over 5,000 miles per tire, and had only five or six flat tires in that mileage; I can remember only four. The increased mileage and reduced expense was to be expected, but I was more pleased with the service than the economy. When one remembers that a car is practically as much out of commission while it has a flat tire as it is with a broken crank-shaft and that constant service is what the physician requires it is easy to understand the advantage of the large tires. The first cost of a 34 by 3½ tire is $48.00; the first cost of a 34 by 4½ tire is $74.59. These prices are taken from an old list but serve for comparative estimation. The first cost is less than double and the increased mileage is more than three times, while the difference in service is inestimable.

Another economy is a good chauffeur, whose employment leads to better service. If the doctor has the time he can soon learn all about the machine, and with a little attention each day can keep a cheap man on the job for rough work, but every machine must have careful and intelligent attention. Unintelligent meddling is worse than none. Better feed oil and gasoline and let her run than turn a hammer-mechanic loose on your car. I have known a man do more harm to a car with a hammer, a chisel and a large wrench in a few minutes than a month's usage would do.

It is better to carry as little extra weight as possible. For this reason the back seats of the larger car (199) are not made over-inviting and I do not carry a wind-shield. The latter is difficult to keep from rattling, and if one keeps down the noise of one's car one can the better detect loose connections, etc., before they have done any harm. It is necessary, however, to be protected from the weather. This large car has a top with a long low hood and a rubber apron which fits snugly around the steering wheel. In cold weather I have a large lap-robe over my knees. In the very bad weather and when driving very hard I wear goggles. These, the top, rubber apron, lap-robe and goggles furnish all the protection I have ever found necessary.

Large lamps are an economy because they keep one out of bad holes. I prefer to have them supplied from a tank rather than from a generator.

It has been my experience that the high-priced lubricating oils are not economical and that the cheaper gasoline, if well strained, answers admirably.

In addition to the usual tools I find that a good rope is most valuable to have in one's kit. This will either pull the other fellow or help one to be pulled. Also it may be tied around the tires and thus furnish traction when chains are not serviceable. It has helped me over very wet grass after a hard rain, out of muddy places and deep soft snow.

A good, intelligent horse is a most delightful companion and to me is preferable to a machine for pleasure; but time is the crying need and it is the time for which we Americans pay. The single-cylinder car is more time-saving than a horse and a four-cylinder car more efficient in this way than a single cylinder. One's need for a car depends on his need for time.

It is also true that the practice of a physician in general medicine is limited only by what he is able to do well during the busy season and an automobile well cared for reduces his limitations, thus allowing more work when practice is slack. If a physician could make arrangements to have the use of a machine during his busy season, and was willing to forego the pleasures of the machine in the summer, I am sure that the automobile would be a paying investment from the standpoint of the most exacting accountant. D.

Makes Your Hair Grow Long and Curly

The use of the car improves your health, steadies your nerves, expands your lungs, reddens the blood, increases appetite and makes life worth living. I haven't tried the aeroplane, but next to flying, autoing is the most exhilarating pleasure that I have known, and besides lightens the burdens of those dreadful night calls.

J. WILTON HOPE, Hampton, Va. (Auto 222).

AIRLESS AND CUSHION TIRES VS. SOLID AND PNEUMATIC

The tire undoubtedly gives the physician greater trouble, and is the source of greater expense, than any other part of his automobile, and anything, therefore, which promises to lessen those evils is always of interest, both to the automobile manufacturer and the user.

Until recently there were only two kinds of tires, namely, solid and pneumatic; hence when we speak of "tire troubles" our minds naturally revert to those two types.

Diagnosing the troubles accompanying the pneumatic tire we find the cause of the trouble to be compressed air and insufficiency of ordinary cotton fabric to withstand the enormous internal air-pressure and the terrible knocks and strains occasioned by contact with uneven road surfaces. It follows, therefore, that a stronger and more durable fabric than the highest grade sea-island cotton must be provided in order to retain the great air pressure, or compressed air must be done away with entirely. Up to date nothing has been produced that will do the work of sea-island cotton, and the best authorities believe that nothing can ever be produced that will even do the work as well.

Quickly detachable and demountable rims have facilitated the operation of removing and applying tires, but they have not removed the cause, and pneumatic "tire troubles" are as frequent and almost as annoying as ever.

Diagnosing the troubles accompanying the perfectly solid tire, we find that the trouble, for the most part, manifests itself elsewhere than in the tire, just as a severe headache may be the result of a defect in the eyes; and on account of the rigidity of the tire, the jar and vibration are so severe as to injure the machine; and repair bills and loss of time and use of the machine while in the repair shop, make the use of perfectly solid tires a source of greater trouble and expense than pneumatics. The solid tire wears satisfactorily and cannot puncture or "blow out" like the pneumatic, but it is too hard and rigid.

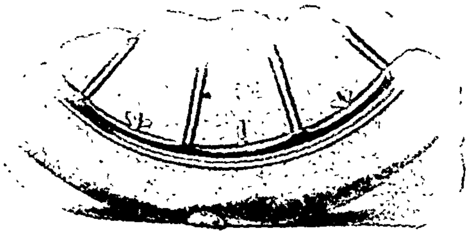

Fig. 33.—Pneumatic tire.

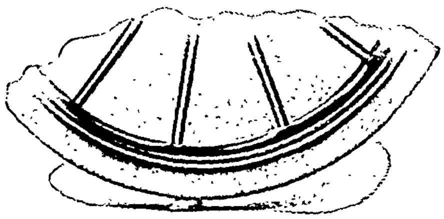

Fig. 34.—Solid tire.

A pneumatic tire absorbs obstructions by removal or displacement of the air at the point of contact between the tire and the obstruction and consequent absorption of the obstruction, and the tire passes over without a jar (Fig. 33). A solid tire rides up over the obstruction (Fig. 34); hence the jar or shock to the machine and occupant.

It follows, therefore, that the ideal tire must be one which will not depend on compressed air for its resiliency, but it must be softer and more elastic than the perfectly solid tire, while retaining its durability.

Taking up the problem, therefore, in a practical manner, we find that the resiliency must be at the point of contact between the tire and the ground so as to absorb the small obstructions that cause jar and vibration. This cannot be secured by springs in the spokes or cushion hubs, or the hundred and one other "patent medicines," but the absorbing medium must be right down at the ground, and if we are to do away with air, we must provide something else which can be displaced, and which is active, lively and resilient; there is only one known substance that can be utilized—rubber.

A fact of very great importance in this connection is that rubber is a non-compressible substance. Press a piece of rubber between your fingers, and it will "give" or compress only in proportion as it can expand elsewhere. You can displace rubber, but you cannot compress it, just as you can displace water by putting your finger into a glass filled with it, but you cannot compress it. If the piece of rubber were encased so that it could not expand, you could not compress it.

If, therefore, the rubber in a tire be so arranged as to permit it to "give" or "displace" all along the tread, when small road obstructions are encountered, you can produce the effect of a pneumatic tire when air is displaced. This is the result aimed at in the different types of "airless" and "cushion" tires, and the tire which is so constructed as best to produce this result is logically the best tire, for it will come nearest to producing the resiliency of the pneumatic, yet retaining the durability of the solid tire.

There are two types of these tires now on the market—one known as the "airless" tire, the other the "cushion" tire. The "airless" tire retains the shape of the pneumatic, and so far as external appearances go, cannot be distinguished from the standard pneumatic, and is designed to fit the standard clincher rims. This type of tire is composed of rubber and fabric and is molded in one operation; it is patterned after a cement bridge having a series of piers or columns of rubber, corresponding to the piers or columns of a bridge and a heavy tread of fabric and rubber corresponding to the road surface of the bridge. When the tire is completed it is just as homogeneous, or completely united, as the cement bridge, for the piers and tread are all molded and vulcanized together in one operation, and the piers will not separate from the tread any more than the columns or piers of the bridge will separate from the road surface. When the "airless" tire, therefore, strikes an obstruction the tire is pressed in at the point of contact, and the tread and pier bulge into the open spaces between the piers, and the obstruction is absorbed into the tire, hence the jar and vibration are practically eliminated. The fabric in its construction keeps the tire from stretching and becoming flabby and soft, and strengthens the piers or columns like guy wires. This type of tire can be retreaded.

The other type—the "cushion"—is made of rubber only, and contains no fabric in its makeup, and instead of having internal cells or open spaces, has a solid mass of rubber around the center of the wheel, but has open spaces on the outside designed to provide places for the rubber to "go" when an obstruction is encountered. This type of tire differs from the standard pneumatic in appearance and size, and cannot be retreaded.

John A. MacMillan, Dayton, Ohio.

NOT A MONEY-SAVER, BUT THE PLEASURE COMPENSATES FOR THE EXPENSE

I am one of the pioneer automobilists in the state. Since my first motor-car (202), I have had two runabouts (203, 204), and now have a little car (205) weighing 650 pounds. This is so new that I have not had time to try it out and therefore cannot speak either for or against it. My location is very mountainous, giving a car the hardest kind of a test. As a matter of economy, the automobile is not a money-saver, but the pleasure derived far more than overbalances this expense. The snow is deep here in the winter, at which time I use a horse almost exclusively. During the summer the horse is often not used for six weeks at a time. For different reasons I shall probably use the horse, on an average, twice a month. My choice is a light-weight, water-cooled car with pneumatic tires. The specifications of one which I have never used (206) come the nearest to being my ideal of a car of any in the market.

C. D. Voorhees, M.D., Sonestown, Pa.

A COMPILATION OF AUTOMOBILE STATISTICS

Some Deductions About Automobiles from the Statements of Many Physician Drivers

With the idea of securing some information in a statistical form concerning automobiles of various types, and physicians' experiences therewith, THE JOURNAL printed* a list of questions to be answered voluntarily by readers. In all nearly 500 replies have been received, indeed they are still arriving, but it was necessary to draw the line when some 434 had been received to allow time for compilation.

For whatever value may be derived from these statistics, thanks are due to the physicians who replied, and we wish hereby to express our appreciation for their cooperation. We have made arrangements to send a copy of the Automobile Key,† giving the names of the motor-cars referred to in this number, to each one who filled out a blank and also to each of the authors of articles—without any further effort on their part.

Of the 434 replies, 96 concerned horses alone; a few, steam and electric cars, as well as motorcycles, railway gasoline velocipedes, etc., and the remainder, 324, concerned gasoline automobiles. The conclusions drawn from the figures are of necessity very general and are to be accepted with some qualifications according to the circumstances, but they are nevertheless interesting and worthy of perusal.

GASOLINE AUTOMOBILES

It will be readily agreed that it is unfair to compare an $850 runabout with a $3,000 limousine or even with a $1,750 touring car. The 324 gasoline cars were divided, therefore, into three classes, cars costing less than $1,000, cars costing $1,000 and up almost to $2,000, and cars costing $2,000 and upward. For the purposes of this summary they will be called Classes 1, 2 and 3, in the order named. In Class 1 were 116 cars in Class 2 were 158 and in Class 3 were 50.

QUESTION 20: EFFECT ON INCOME

	Increased.	Decreased.	No Increase.	Not Answered.
Class one	69	1	35	11
Class two	82	1	56	19
Class three	27	0	19	4
Total	178	2	110	34

QUESTION 21: DOES IT PAY TO OWN A CAR?

	Yes.	No.
Class one	97	21
Class two	117	34
Class three	34	12
Total	248	67

The affirmative answer to this question as indicated by the figures is very emphatic. Of course, as might be expected, these answers involve a variety of considerations. Some have said "Yes" with the purely financial aspect of the question in mind, while others have thought, not only of the increased number of patients they can see, but of the time saved and relief from the tedium of getting around, with more leisure to themselves, or more time for study. Still others have thought most, perhaps, of the increased joy of living through the exhilaration afforded. These latter have recognized that there are other things in life besides the dollar and that the word "pay" does not relate exclusively to money.

QUESTION 22: STYLE AND PRICE OF CAR PREFERRED

	Price			Style	
	Low.	Medium.	High.	Runabout.	Touring.
Class one	35	60	2	92	13
Class two	20	111	6	97	23
Class three	3	25	9	22	10
Total	58	196	17	211	46

The above figures mean that of those who now use low-priced cars 35 still recommend cars of that class, while 60 recommend cars of medium price, and 2 those of high price. Of those now running a medium-priced car 111 still recommend that sort of car, while 20 recommend a low-priced car and 6 a car of high price. In class three only 9 recommend the high-priced car, which they are now using; 25 of these recommend the medium-priced car, but only 3 a low-priced car.

As will be seen, the medium-priced runabout is vastly in the lead, as was probably to be expected.

The following tables give averages which will explain themselves:

QUESTION 16: AVERAGE COST OF MACHINE

Class one	$ 747.65
Class two	1,192.18
Class three	2,564.74

QUESTION 18: AVERAGE COST OF MAINTENANCE AND DEPRECIATION PER YEAR

Class one	$282.95
Class two	492.00
Class three	716.37

QUESTION 3: AVERAGE ANNUAL INCOME

Class one	$3,720.20
Class two	5,028.84
Class three	8,322.00

QUESTION 7: AVERAGE MILEAGE FOR ONE YEAR

Class one	5,004
Class two	5,397
Class three	7,933

QUESTION 19: PERCENTAGE OF MILEAGE FOR PLEASURE

Class one	18 per cent.
Class two	17 per cent.
Class three	22 per cent.

QUESTION 8: AS TO EMPLOYING A CHAUFFEUR

	No.	Yes.
Class one	11	5
Class two	146	9
Class three	40	7
Total	297	21

This last tabulation simply shows how great is the majority of owners who run their own cars.

It will be seen that while there is considerable difference between the prices of cars of the low and high classes, the average mileage of each class does not show a great difference, the high-priced class, being used more for touring purposes,

---

* The questions were as follows:

1. Your name and address? 2. Size of town? 3. Yearly income?
4. Are your roads good, fair or poor? 5. Hilly or level?
6. Radius of territory you cover?
7. What is your yearly mileage? 8. Do you employ a chauffeur?
9. Coachman? 10. Name of car? 11. Number of passengers?
12. Kind of tires? 13. Gasoline, steam or electric?
14. How long have you used autos?
15. For horses: what is your total investment including vehicle and harness?
16. For auto: what is your total investment including equipment?
17. What does your expense average per year, in using horses, including feed, care, repairs, depreciation, etc.?
18. What does your expense average per year, in using an automobile, including operation (gasoline or electricity), tires, care, repairs, depreciation, etc.?
19. What per cent. of your mileage is for pleasure?
20. What effect has the owning of a car had on your income?
21. Aside from the rest and pleasure, do you think that it pays you to own a car?
22. As a business proposition, would you recommend, for one in your position, a low, medium or high priced car—a runabout or a touring car? 23. Remarks.

† A copy of this key will be sent to anyone who sends a self-addressed stamped envelope.

FAVORABLE EXPERIENCE WITH A ONE-CYLINDER CAR

My car is a 1910 model, one-cylinder runabout (140), with non-pneumatic tires, and I am sure from my own experience that it will take one or two passengers anywhere that any car could take them regardless of size, price or power. The first car I owned was a 1907 stanhope (209), which gave me good service, but the inaccessibility of the motor, which was under the body, a wrong idea altogether, was a drawback in many ways too numerous to mention. The car I am using now has the motor easily accessible, which is a great consideration. A single cylinder means reduction in a number of parts, less expense and less trouble. It also means longer life. My old car is as good as ever so far as the motor is concerned and it has only one cylinder. The argument that some speak of in favor of a two or a four-cylinder engine, that should one go wrong the rest will bring you home, is absurd. What would you say to a man who would sell you a horse and tell you to take another horse along for fear one might die, then you would have a horse to get home with? My car makes no more noise than many of the two or four cylinders. I could break the speed law and get arrested any old time. What then is the use in keeping two or four horses to do your work if one horse will do it? Great motor power in a heavy car is like having money wasted in stock which does not pay your dividends. It is there but you do not get the use of it—that is, you can't realize any more on it than you would if you only had half or a fourth the amount of money invested. A heavy automobile has exactly the same effect. The fewer parts the less likelihood there is that something will go wrong. The springs on this car are easier than on any other car made because they are coil springs. I am sure on the points of first cost, which is $485, economy, reliability, accessibility, easy riding, and in every other way for a one or a two passenger car this car is away ahead of all the others. I am greatly pleased with the tires (210) which I wish more physicians knew about. There is no question but that they ride just as easy as do the pneumatic, at least they do on this car. The springs may have something to do with it, but I surely would not go back to pneumatics again. They are as resilient as a pneumatic tire and are neither solid nor pneu-, require no pumping and cannot puncture nor blow out, to a physician means something.

J. E. Asay, M.D., Rock Island, Ill.

A COMBINATION TRANSFORMABLE RIG

A few years ago I drove fine horses and loved them. When the auto epidemic raged in my neighborhood I fought it off until I was practically alone, I so loved my beautiful bays. When I finally decided to get an auto, contrary to my usual way of doing things, I selected the simplest and most inexpensive machine (215) built, possibly as an apology to my poor horses.

I have since learned that the only mistake I made was that I should have bought two. It was so simple my wife learned to run it. I have driven my machine thousands of miles since I have had it, all over the country, day and night, summer and winter, on all kinds of roads, and what do you think? No more horses for me; they eat too much, they go too slowly, they require too much care. My auto costs me less, is always outside the door waiting for me, and is as much a necessity as my telephone.

It is equipped with two sets of wheels, one with pneumatic tires and the other with solid tires, so I am ready for all seasons of the year and never have to bother with horses. It is a classy runabout one minute and converted into a four-passenger rig the next minute.

J. H. Veatch, M.D., Marine, Ill.

A Terse Comparison

Costs less than one horse and does more work than three, and is much easier on the doctor.

C. H. Miller, Chicago (Auto 230).

Air Versus Water

For this climate I can see no particular advantage in air cooling. The antifreezing solutions have given me satisfaction, and the water-cooled engines run more smoothly and require less adjustment.

C. S. Kalb, Spokane, Wash. (Auto 218).

The Simple Car

The more simple and less complicated a car, the better. A first-class, medium weight, medium priced car, given reasonable care, will not only stand a wonderful amount of hard work on all kinds of roads and in all kinds of weather, but a wonderful amount of abuse as well.

K. W. B., Nebraska (Auto 224).

Just Like Fishermen

The reason some auto owners have more expense than others is the overcharging, false representation and grafting of garage owners. There is not one automobile owner in a hundred who will state his true expense. It seems that a truthful automobile owner is a rarity.

W. A. Stoecks, Davenport, Iowa (Auto 223).

Get a Second-Hand Car to Start With

To the man in my position I would say, get a good second-hand car, as you must learn to run and care for it yourself, and you can get this knowledge most cheaply in this way. Don't expect too much at first. You will have to give a few public demonstrations on the main street, but if your religion will stand this you can be sure it is of the proper brand and you will soon learn to have things in order before starting. After a year's experience you will be in position to buy a new car and get unbounded satisfaction out of it.

C. H. Fox, Clarks, Neb. (Auto 225).

Does Driving a Car Become Automatic?

A point which seems not to have been raised in any of the answers received by The Journal is discussed *pro* and *con* by correspondents in the *British Medical Journal* of recent date. Dr. Allan Wilson writes that a motor car for a medical man "can scarcely be considered a boon or a blessing to his patients, because, when he is going from house to house on his daily rounds, his thoughts and attention, that should be occupied with the contemplation of the nature and treatment of the diseases which come under his notice, are, by necessity, directed to the steering of his car."

Dr. Thomas Fentem replies by saying: "My experience is that one arrives at the patient's bedside much more alert and less jaded after a long round than with horses; and, getting over the ground more quickly, one reaches home earlier than one could with horses. One therefore has more leisure to give to the consideration of the patients' cases in the quiet of one's study and among one's books, and that surely is better than trying to do this sitting beside a coachman; even if one's thoughts are stimulated by such accompaniments as blinding snowstorms, driving rain, gales of wind, and such like.

"The driving of a car becomes after a short time largely automatic, and this applies, perhaps, most of all to the steering, the task which Dr. Wilson appears to think requires such deep mental application as to banish all else from one's mind."

Dr. F. L. Nicholls writes: "One would almost feel inclined to think that Dr. Wilson had made one or two attempts to handle the ribbons or drive a motor and found it too much for his nerves; and if such is the case he is certainly a wise man to depend on his coachman to see him safely on his rounds, but I cannot allow the statement that a driver's whole attention must be given to steering to avoid accidents to pass without protest. If such was the case I pity the poor driver, for at the end of a week his nerves would be in such a state that he would be good for nothing but darning stockings or doing patchwork, even if he was lucky enough to keep out of an asylum.

"Dr. Wilson does not appear to know that all these actions to an experienced and skilled man are almost entirely automatic. The eye and hand do the work, leaving the brain free for the consideration of any matter its owner may desire. I do not speak without experience, for I have for over forty years had the handling of horses, including the breaking-in of young ones, and for over five years I have driven a motor, and I can assure Dr. Wilson that the only time when my brain is 'jumpy' is when I have relinquished the reins or wheel into some other person's hands. I am then anything but at ease; but directly I have again resumed my usual and proper place my brain is at ease and ready for the consideration of the most serious subjects connected with my practice."

OCULAR PALSIES IN TABES*

WILLIAM CAMPBELL POSEY, M.D.
PHILADELPHIA

The importance of examining the eyes of tabetics has long been recognized by neurologists, for the ocular symptoms often precede all other sure signs. Indeed, so constant and characteristic are the pupillary, muscular and optic-nerve changes in this disease that, given in addition to even one of these, the history of previous syphilitic infection and another characteristic sign of tabes, such as loss of knee-jerks, diminution in muscle tonus of the legs, or a marked disturbance of the bladder or sexual functions, the diagnosis of tabes becomes very probable. It is not the purpose of this paper, however, to treat of the ocular symptomatology of tabes in general, but to dwell particularly on the palsies of eye muscles, and especially of the extra-ocular muscles, which are observed so frequently at some stage or other of the disease.

In attempting a generalization of the extra-ocular palsies, it may be remarked that, while they resemble in many particulars palsies of eye muscles due to other causes, they manifest certain characteristics, which, while not in themselves peculiar to tabes, are at least highly suggestive of the presence of that disease.

The first and chief of these is their transient tendency, for it is an almost constant experience that the palsies which appear in the early stages of the disease vanish after periods of persistency ranging from but a few hours to two or three weeks, and, moreover, while it is true that the palsies which occur in the later stages are as a rule permanent, even these may be transient and may totally disappear, usually after a longer period, however, than when they are observed at the commencement of the disease.

The careful historian will often elicit the occurrence of diplopia in very many cases from patients who are loath to believe that the attacks of double vision from which they suffered even months or years before other symptoms of tabes developed had any connection with their general nervous disorder.

As illustrative of a fleeting palsy occurring in the early stages may be cited the case of a man, aged 45, who consulted me in 1895 on account of a paralysis of the right external rectus muscle. He confessed to having had an initial sore when 25 years old, but as he had received prompt and, as he thought, efficacious antisyphilitic treatment and as his health had been uninterruptedly good, he considered himself to be well. In addition to the extra-ocular palsy noted at the examination, Argyll-Robertson pupils were present, and his physician reported other signs of early tabes. Potassium iodid was administered in ascending doses, and the diplopia totally disappeared after two months' duration. Although this case has passed from my observation, it was reported to me five years ago that the patient was still living, and, though manifestly the subject of tabes, he seemed to suffer but little inconvenience from it.

Another patient, M. J., aged 53, a patient in the Philadelphia General Hospital, gave a history of having had diplopia six years before admission and that it lasted two years. When the diplopia disappeared he began to notice occasional jerkings in the right foot and his gait became disturbed. Examination which I made six months ago revealed no ocular palsies, and the neurologic report was as follows:

"Slight ataxia in upper extremities. Romberg symptom. Ataxic gait. Hypotonia in lower extremities. Knee-jerks lost, etc." Syphilis was denied.

As an example of a transient palsy occurring in a late stage of the disease may be mentioned the following:

J. C., admitted to nervous wards of the Philadelphia General Hospital in 1896, aged 51, with the history of an initial luetic lesion twenty years previously. It was elicited on admission that the earliest symptoms of tabes had manifested themselves six years previous to admission as "cutting" pains in feet and legs. Girdle pains were also present. Two years later gastric and bladder symptoms supervened. Argyll-Robertson pupils were present in both eyes, knee-jerks were lost, ataxia was noted in the upper and lower limbs, but the extra-ocular movements were uninvolved. Six years after admission diplopia appeared (due probably to a paretic condition of the right superior rectus) and persisted for several months. The double vision then gradually disappeared and did not return during the two years or more during which the patient still continued to retain sight, vision being gradually lost at the end of that period from optic atrophy. When I examined the patient six months ago the movements of both eyes were found to be markedly incoordinated, not only from the incoordination of blindness, but also from a paretic condition of the extra-ocular muscles, which seemed to reside chiefly in a weakness of the right superior rectus muscle.

Thomas, who analyzed 111 cases of tabes from the Hopkins clinics in 1899, found the initial symptoms to consist of diplopia in 6 instances, and of other eye symptoms in 14 instances. Diminution of vision was the initial symptom in 4 cases. Double vision and dimness of vision were associated once and double vision with other symptoms 7 times. Ptosis was the first symptom associated with pain twice. Of all the symptoms, pain was the one most generally complained of, being present in 57 cases; ataxia was the initial symptom 24 times, numbness of extremities 6 times, paralysis of bladder 5 times, gastric crises 4 times, paralytic attacks twice, while loss of sexual power, mental symptoms and neurasthenia were recorded as initial symptoms in one instance.

---

* Read before the Buffalo Ophthalmological Society, Dec. 11, 1909.

Thomas did not mention in how many of his cases the diplopia disappeared, but I think that it has been my experience that the palsies vanish, for a time at least, in perhaps 90 per cent. of the cases which I have had under observation. This percentage is based on an analysis of the histories of 60 cases of tabes taken from my own private and hospital records and from the study of 28 cases of advanced tabes which I recently made in the wards of the Philadelphia General Hospital, through the courtesy of Drs. C. W. Burr and William G. Spiller, neurologists to the institution.

In addition to the transient tendency which tabetic ocular palsies exhibit must be noted a very marked disposition to recurrence, either the same muscle being repeatedly palsied, or the palsy appearing in another muscle or muscles, shortly after it has disappeared in one governed by another nerve. An interesting case of this nature is reported by Pel, in which oculomotor palsy, which was the first indication of the disease, recurred 7 times, after having completely disappeared 6 times. This disposition to recurrence is well exemplified by a case under observation at the present time, in which the diplopia, which previously appeared eight years ago, disappeared after about two months' persistency, to reappear three years later for a period of three months, two years later for three months, while the present attack came on one month ago and is still persistent. The muscle occasioning the diplopia at present is the left inferior oblique; in the other attacks the patient states that one object was always higher than the other and there was some lateral displacement, but he was unaware of the precise muscle or muscles which the oculists to whom he went for relief found implicated. This [illegible]t, a man, 49 years old, contracted syphilis when [illegible]9; he now shows evidence of beginning atrophy of [illegible] optic nerves, with other well-developed signs of [illegible]bes. Argyll-Robertson pupils are present in both eyes.

So fleeting is the palsy in some instances that it may pass away in a few hours, while in others it may persist for years, the muscle regaining its power only after long loss of function. This return of the muscle to its normal action after even years of paralysis should be recognized by ophthalmic surgeons and should tend to discountenance operations on the eye muscles of tabetics.

As illustrative of this type may be cited the case of R. L., a woman, aged 60, who consulted me at the Howard Hospital in 1896 on account of double vision, which examination showed to be due to a paralysis of the left external rectus muscle. There was a history of recurrent attacks of double vision of a somewhat similar nature having occurred for some years previously, but these attacks had been fleeting, whereas the double vision for which she then sought relief had persisted for six weeks or more. The knee-jerks were absent, Argyll-Robertson pupils were present in both eyes and the discs were partially atrophic, the fields being contracted. There was a probable history of syphilitic infection some fifteen years previously. Potassium iodid was administered for three months in high doses without affecting the palsy. The patient then passed from observation for two years, when she returned for a change of glasses. Examination at this visit showed all the extra-ocular muscles to be functioning, the patient asserting that she had not been troubled with the double vision for some two or three months previously. In this case the palsy completely disappeared after a persistence of about two years. Recent efforts to find the patient, with a view to determining the progress of her disease, have been ineffectual.

Another peculiarity of tabetic palsies is that they are usually dissociated, i. e., paralysis of the levator or rectus internus alone, the palsy following no particular rule. This is especially true when the palsy appears as an initial symptom, when it rarely affects all muscles or muscle groups supplied by a single nerve.

In studying the relative frequency with which the several eye muscles become affected in tabes, Uhthoff found the oculomotor involved in 54 per cent. of his cases, the abducens in 33 per cent., the trochlearis in 8 per cent. Ophthalmoplegia externa existed in 5 per cent. and isolated ophthalmoplegia interna in 5 per cent. Beyer's, Stock's, Erb's, Fournier's and Charcot findings were similar. Of 100 cases of tabes seen in Schoeler's eye clinic, the oculomotor was involved in 26 instances. From an analysis of 60 of the cases which I observed and which lent themselves to such a study, it was found that the oculomotor was at fault in 30 of the cases, the abducens in 6, and the trochlearis in 2. In the remaining 22 cases the paralysis was of a mixed type. Complete unilateral oculomotor palsy occurred in 3 instances. Complete palsy of the oculomotor in all its branches is very rare, Uhthoff meeting it in but 5 per cent. of all his cases, and in but a very small proportion of these was the palsy binocular.

An interesting case of complete palsy of the right third and sixth nerves and of a partial implication of the left third nerve was one of the cases placed at my disposal by Drs. Burr and Spiller and studied by me. This patient, a man, aged 39, had noted that five years previous to his admission to the hospital in 1907 the left pupil did not contract and that he had some difficulty with vision. About the same time a numbness was remarked in the right foot and two years later in the left leg. Girdle pains followed later. Examination which I made six months ago showed the conditions just mentioned. Argyll-Robertson pupils and Romberg sign were present, and ataxic gait, with absent knee-jerks, was noted, with some impairment of sensation in lower extremities.

According to Oppenheim, associated palsies never occur in tabes, but Uhthoff, though stating that the finding must be very rare, cites a case reported by Chvostek with bulbar symptoms, in which there was left-sided ptosis, palsy of the left rectus internus and of the right rectus internus in association with paretic nystagmus.

I found paralysis of both external rectus muscles in two cases. One of the patients, G. H., a man, aged 41, was admitted to the nervous wards of the Philadelphia Hospital Oct. 3, 1907, with well-marked optic atrophy. A period of double vision had preceded the blindness, however, by some five years. The sexual power was lost at the same time that the blindness developed, ataxia in the lower extremities manifesting itself somewhat later. My examination six months ago revealed complete atrophy of both optic nerves with paralysis of both external rectus muscles; knee-jerks lost; ataxia in both upper and lower extremities.

Wilbrand and Saenger observed that isolated palsy was an accompaniment of the initial stages, and generally disappeared, persisting as a permanent finding but very rarely, i. e., in but 3.3 per cent. of 302 cases. Marina, however, found the paralysis to be persistent in 10.6 per cent. of the 150 cases observed by him.

Although the palsies may occur at any stage of the disease, most authors have observed them relatively early, 83 per cent. of Berger's cases and 80 per cent. of Gowers' occurring in the initial stage. Uhthoff's experience was similar, and he considered the palsies to be analogous to the appearance of the Argyll-Robertson pupil and optic atrophy.

After studying an enormous number of cases of tabes, taken from all sources, Uhthoff found that palsy of the eye muscles occurred in from 20 to 22 per cent. of the cases. Moeli placed the figures at 22 per cent., Reumont at 17 per cent., Marina at 19.5 per cent., Leinbach at 16 per cent., Tumpouski at 21.7 per cent. Mann found palsies in 30 per cent. of his cases. It should be noted, however, that the percentage of palsies observed in an eye clinic is necessarily higher than that observed in a clinic devoted to nervous cases, since the moment double vision is complained of the patient seeks the former. In the rare cases of true tabes in children, Uhthoff found ocular palsies in about 14 per cent. of the cases, while Argyll-Robertson pupil occurred in 65 per cent. and optic atrophy in 45 per cent.

According to the figures just quoted, palsy of the eye muscles in tabes in adults is much more common than atrophy of the optic nerve, which, from Uhthoff's figures, is seen in from 18 to 20 per cent. of all cases. They are not observed, however, in the initial stages of tabes as frequently as the Argyll-Robertson pupil or as lancinating pains, or again as the loss of reflexes, as will appear from the table prepared by Fehre and quoted by Uhthoff in his remarkably learned dissertation on this subject in the second edition of the Graefe-Saemisch "Handbuch":

	Per Cent.
1. Disturbances in sensibility (in the widest sense)	92
2. Lancinating pains	85
3. Loss in patellar reflex	83
4. Argyll-Robertson pupils	79
5. Romberg phenomenon	71
6. Ataxia	55
7. Bladder and rectal symptoms	50
8. Gastric crises	43
9. Pupillary inequality	41.5
10. Paresthesias	36
11. Headache and attacks of dizziness	40
12. Involvement of cerebral nerves	40
13. Girdle sensations	36
14. Weakness in legs	30
15. Palsy of ocular muscles	30
16. Optic atrophy	21.5
17. Cardiac neuroses	21.5
18. Psychic disturbances	21
19. Diplopia	19
20. Laryngeal crises	15

Rarely muscles other than the ocular muscles may be palsied at the same time. Thus a case reported by Turner, that of a man of 40, there was some ptosis and also some bilateral palsy of the soft palate and paralysis of the vocal cords. Rarely also, instead of an ocular palsy, a blepharospasm may be noted or a blepharospasm may precede the development of ocular palsies.[1]

Of 1,088 cases of tabes seen by Grosz, Berger, Bernhardt, Leinbach and Bonar, 222, or 20.4 per cent. had optic atrophy. As this number is so large, this percentage probably represents the true frequency of this symptom in tabes.

It is of interest to remark that, from an analytical study of 127 cases, in which optic atrophy occurred 55 times, Mann found no tendency for the involvement of the nerve to lighten the future course of the disease. It must be remembered, however, that the form of tabes which begins with optic atrophy is often for a long time combined with a loss in power of the roots of the thoracic nerves, when all other symptoms are absent. According to Mann, the same holds good not only for optic atrophy, but is also the rule in cases presenting Argyll-Robertson pupils and ocular palsies, both of these symptoms being sometimes associated for a long time solely with anesthesia of the trunk.[2]

Abducens palsy occurred in 13 per cent. of Uhthoff's cases, though binocularly in but 2 per cent. This observation is of considerable moment in establishing a differential diagnosis between tabes and cerebral syphilis, multiple neuritis, intoxications, etc., in which latter conditions binocular isolated disease of the abducens is not unusual. Authorities agree that in tabes abducens palsy is, as a rule, incomplete and but rarely permanent.

Uhthoff's statistics show isolated ptosis in about 4 per cent. of his cases; indeed, so much stress does this observer lay on this symptom that he believes, in common with Wilbrand and Saenger, that a unilateral or bilateral transient ptosis, complicated by one or more pronounced tabetic symptoms, such as Argyll-Robertson pupil, lancinating pains, failure of knee-jerks, optic atrophy, etc., makes the diagnosis of tabes extremely likely. Wilbrand and Saenger and Kahler found the combination of ptosis with abducens palsy not infrequent in the early stages of tabes, while Uhthoff's cases, on the other hand, showed a frequent combination of palsy of the levator with that of the superior rectus.

It has long been a mooted question just what influence syphilis, the underlying factor in so many cases of tabes, might have on the occurrence of the palsies. Berger, for example, found, in 56 cases of tabes studied by him which had ocular palsies, that a direct syphilitic history was obtainable in 25, a specific infection being denied in 31. He asserted also that his observations led him to infer that the palsies in the syphilitic cases showed a greater tendency to be permanent than in the nonsyphilitic ones, the syphilitic palsies persisting on an average of six and one-half months, the non-syphilitic but two months. His figures showed also that the former class of palsies exhibited a greater tendency to be multiple than the latter. Uhthoff's figures, on the other hand, do not substantiate Berger's, and this careful observer has not been able to satisfy himself that palsies occurred more frequently in cases of tabes with a syphilitic history than in those where no syphilitic history was obtainable. Uhthoff concedes, however, that a subject with syphilis affected with ophthalmoplegia is oftener later affected by tabes than those with ophthalmoplegia without previous syphilitic infection. Spiller believes that these statistics may be unreliable, for, he says, "many persons deny syphilitic infection with full knowledge of the infection." He thinks statistics based on the Wassermann reaction will be more valuable. At present this reaction seems to be obtained in about 60 per cent. of all cases of tabes.

As a further point in the differential diagnosis between the ocular symptoms of tabes and cerebrospinal syphilis may be cited the observation of Groenouw, that the Argyll-Robertson pupil is generally indicative of tabes, unilateral ophthalmoplegia interna of syphilis. Again, according to Fournier, syphilitic palsies as a rule affect the entire nerve or a great number of its branches, while a single muscle is involved in tabes. It has been my experience that inequalities in the size of the pupil and disturbances in its reaction are found in the early stages of cerebral syphilis, often associated with optic neuritis, while palsies of the extra-ocular muscles, as a rule, belong to the later stages. When syphilitic palsies do occur in the early stages they develop more gradually and persist longer, tabetic palsies, as has been said, manifesting a tendency toward speedy disappearance and frequent recurrence. Conjugate deviations and ophthalmoplegia externa are caused almost exclusively by syphilis.

---

[1] Posey and Spiller: The Eye and Nervous System, p. 502.

[2] After a critical reading of this paper, Dr. W. G. Spiller has told me, "It is very important to separate those cases of tabes in which optic atrophy is an early sign from those in which it occurs late. It is only in the former that the atrophy seems to have any influence on the course of the disease, and while it does not invariably modify the course, it does so in a sufficient number of cases to show it has a decided influence. Indeed Déjerine has employed the term of 'tabes arrested by blindness.' Statistics which include the cases of early and late optic atrophy are valueless for this purpose. Early optic atrophy is not very rare, tabes without implication of roots below the thoracic is distinctly rare, and early optic atrophy is frequently seen with the usual lumbo-sacral type of the disease. Byron Bramwell questions the influence of optic atrophy at any stage on the course of the disease."

Ophthalmoplegia interna is rarer in tabes than in other affections of the nervous system. Mann, for example, finding it but 19 times among 127 cases of tabes (14.9 per cent.). Of 30 cases of ophthalmoplegia interna seen by Uhthoff, syphilis was the causal factor in 23.3 per cent., tabes in 10 per cent., progressive paralysis in 6.6 per cent., trauma in 6.6 per cent., extreme cold in 3.3 per cent., intracranial disease in 6.6 per cent., while no etiologic factor could be found in 40 per cent. of the cases. Uhthoff found ophthalmoplegia interna with unaffected external eye muscles oftener in tabes than with palsied extra-ocular muscles. Wilbrand and Saenger's observations tallied with his, but 14 per cent. of the more than 100 cases of tabes and ophthalmoplegia cited by them exhibiting ophthalmoplegia interna in association with palsy of the extra-ocular muscles. In the remaining cases, Argyll-Robertson pupils were observed relatively often, normal pupils but rarely. In view of this fact, Uhthoff has suggested that a non-tabetic ophthalmoplegia can readily be differentiated [illegible] one due to tabes by the presence of an unaffected [illegible] It must be remembered, however, as Gowers has pointed out, that a true syphilitic ocular palsy may coexist with locomotor ataxia; indeed, tabes often cannot be distinguished clinically from syphilis of the nervous system.

According to Gowers, the initial symptom of tabes rarely appears within the first three years after the chancre; indeed, in one of his cases it was not noted until forty years afterward. Spiller thinks that usually about nine years elapse after the initial lesion before syphilitic palsies of the eye muscles appear.

It may not be amiss in this connection to refer briefly to the recent paper by Putnam,[3] in which exception was taken to the almost universally accepted opinion that syphilis was the sole cause of tabes, and stress laid on the necessity of considering other factors in the etiology. In the discussion which followed the reading of this paper, Allen Starr stated that he was utterly unable to find any syphilitic taint in 20 per cent. of his private cases of tabes, and it was elicited that Gowers had positively stated that syphilis could be excluded in 10 per cent. of all cases of tabes.

There is good evidence that tabes is not always directly the result of syphilitic virus, but results from parasyphilis from some toxic substance produced within the body. Indeed, according to Fournier, the comparative mildness of the primary constitutional symptoms in most syphilitics who ultimately become tabetic almost seems to indicate that when the syphilitic virus expends itself in severe primary and secondary manifestations there is less tendency to the subtle poison, which proves so disastrous to the nervous system.

The pathogenesis of ocular palsies in tabes is still in doubt, but the views of most neurologists, however, are probably best expressed by Fraenkel, who states that they are either pathologic occurrences of another nature than the general disease they are implanted on, or they are a part of the general disease. If they belong under the first category they share with the general disease the common etiology only, i. e., the syphilitic infection, and are pathologically primary or secondary nerve inflammations in distinction from the pathologic lesion of the general disease—a primary degeneration of the sensory neuron. The first type is oftener seen in those cases that are rather forms of multiple cerebrospinal syphilis of the tabetic type, and the second in the class of cases that incline toward the picture of a genuine tabes. In the first instance they may, therefore, be looked on as syphilitic ocular palsies occurring in a case of multiple cerebrospinal syphilis of the tabetic type, and in the second instance they are essentially the same phenomena as the motor phenomena in the extremities of tabetics.

It is for the second type that the view of a primary sensory origin seems to Fraenkel to be justified.

In their earlier stages, Fraenkel believes the palsies to be simply due to the loss of tonus which is mediated through disease of the sensory neuron, while later on when, owing to the long duration or the severity of the process in the sensory neuron, the motor neuron has undergone secondary changes, the palsies are more lasting, more extensive, and their immediate cause found to consist anatomically in degeneration of the nucleus, nerve trunk or muscle. Fraenkel is of the opinion that this view is not only quite compatible with the clinical and anatomic characteristics of the type of palsies outlined above, but receives further support from the fact that it permits a uniform pathogenetic conception of the general disease.

According to Uhthoff, an ependymitis in the third and fourth ventricles, as well as in the aqueduct of Sylvius, although found but relatively seldom post mortem, is to be regarded as the pathologic entity in cases of tabes which exhibit ocular palsies, while the transient nature of the palsies is accounted for by Kahler and Dufour by changes in the circulation with ependymitis and vascular dilatation. Strümpell, on the other hand, attributes the transient character of the palsy to peripheral changes in the nerves of the ocular muscles, ascribing the permanent palsies to lesions in the nuclei and roots of the nerves. Finally, there are others, like Basso, Rieger, Forster and Berger, who ascribe the fleeting character of the palsies to sympathetic vasomotor influences.

In concluding this paper, which has dealt with the true muscle palsies of tabes, I would also call attention to certain weaknesses or pareses which may be frequently demonstrated in individuals with cerebrospinal sclerosis. Often these may be diagnosed by the employment of the Maddox rod; more usually, however, they can be made manifest with the ordinary test for diplopia at the end of the excursions of the different muscles. Such pareses must be differentiated from static muscular insufficiencies, and account taken of their shifting and transient tendency in efforts toward their correction, by the incorporation of prisms in the lenses correcting any refraction errors.

I desire to express my appreciation of the honor which the ophthalmologists of Buffalo and its vicinity have done me in requesting me to appear before them, and to thank them for their courteous attention during the reading of my paper. And while perhaps nothing has been said but that is familiar to all, nevertheless I trust that the citation of the statistics of the large European clinics as well as my own experience, insignificant as it may be in comparison with the monumental work of Uhthoff and others, may, nevertheless, stimulate a more general interest in the prompt recognition of a disease whose successful treatment often rests on its early diagnosis.

THE RELATION OF THE UNIVERSITY TO THE MEDICAL SCHOOL *

JACOB GOULD SCHURMAN
President of Cornell University
ITHACA, N. Y.

The American people are universally distinguished for their business ability and business successes. We live, however, in a world of universal compensations and retributions. If we have an enormous business talent which has won for us a name in the field of trade and commerce, we tend to draw into this province all our other interests. The pulpit and the press are not infrequently denounced as organs of syndicated wealth. In this very city of Chicago, the colleges and universities of the country have recently been declared worthless by a multimillionaire citizen because their graduates have not been trained in the ways of money making. And if in this presence I do not say that the medical profession has been commercialized I do not hesitate to assert that many medical schools and colleges have been established for the pecuniary benefit of their promoters, with the result that we now have in the United States almost as many of these institutions as all the rest of the civilized world, and our standards of medical education are a disgrace to the nation and an outrage on humanity.

The personal profit of individuals has been the most powerful and prolific motive for the multiplication of medical colleges, as it has also been the most pernicious. Fortunately, however, the general spirit of the age, as well as higher ideals of professional education, are working against these commercial medical schools. Not only are the motives of their founders and supporters better understood, but the superiority of medical schools founded on a different basis throws them more and more in the shade, while the growing costliness of a sound education in modern medicine makes their puny efforts ridiculous. At the same time there has been a growing appreciation of the fact that every professional school to be vital and efficient must be a department of a university. Under the influence of these ideas and agencies I have no doubt that the number of private-enterprise medical colleges is destined rapidly to disappear in this country. And I need scarcely say to this audience that this process is already hopefully under way.

I turn to a second motive for the establishment of medical colleges which deserves more consideration than it has hitherto received. I am, indeed, firmly persuaded that no medical school of the highest class can be maintained apart from a university. But I am equally persuaded that no university, merely because it is a university, is justified in founding a medical college. There has been a general impression not only in university circles, but among the members of the medical profession, that a university needed a medical department to round out its organization, and, as it were, to complete its existence. This belief is without warrant in history. It is true that the oldest university in the world, the University of Salerno, had a medical school, and was, indeed, nothing but a medical school. But within a generation came the universities of Bologna and of Paris, the one famous for law and the other for theology, and neither of them in the days of their first glory possessed a medical department. In his great history of universities Rashdall shows that some of the most famous of these institutions had only one or two departments, and that no particular faculty, medicine or any other, can be regarded as essential to the idea of the university, as that institution developed among the nations of Europe. The word university has nothing to do with universal knowledge. It means, on the contrary, merely a guild or corporation. When the founder of Cornell University declared that he would found an institution where any person might find instruction in any study, he formulated a brand-new idea of a university. Yet even at Cornell that idea remains at best an ideal, so vast is the sum total of human knowledge, so varied the fields of investigation, and so costly the maintenance both of instruction and research. And without special endowments, and large endowments too, neither Cornell nor any other university would be justified in the establishment of a medical department. The appeal that such a department is necessary to make a complete university is, as I have shown, historically without justification. And in any event to establish a university department in medicine which you have no special funds to maintain is to be a party to fraud on the public. This is especially true at the present time when, owing to the advance of science and the indispensableness of making provision for it in the curriculum, medical education is the costliest education given at our universities. I recall with satisfaction that on different occasions before the establishment of our own medical college at Cornell University, when I was solicited to "adopt" this or that medical college as the medical department of Cornell, I always replied that I did not want a medical department unless it were as organic a part of the university as any other college; nor would I favor the establishment of one without adequate special endowments for its maintenance. I may add that the members of the medical profession with whom I dealt were invariably amazed at the position I took, and in some cases felt it an affront to themselves that I was so mercenary and autocratic as to decline the offer they made me of eminent men unless the university had the right to control them and endowments to support their work! These recollections are from twelve to eighteen years old. And when I say that the position which I took in those years is now the position of the leaders of the medical profession, I may be pardoned for finding in that circumstance a striking evidence of the great advance which has been made in so short a time on the subject of medical education.

I have spoken of the costliness of medical education. In no other field has science brought such a wealth of new and fruitful discovery. All scientific work is expensive, and the medical sciences the most expensive of all because they deal with the complex phenomena of human life. All education in engineering science is also expensive. But engineering rests in a last analysis on the sciences which deal with energy and motion. And these

---

* Address delivered before the Joint Conference of the Council on Medical Education and the Committee on Medical Legislation of the American Medical Association, Chicago, Feb. 28 to March 2, 1910.

practice of medicine or surgery. Now we have reached a point in the higher education of this country in which it is recognized that the proper time to begin professional work or to specialize with reference to that professional work is at the end of the sophomore year in college. I have no time here to argue this position. But I may say that it is a conclusion which has been reached both by the National Association of State Universities and by the Association of American Universities; the former organization embracing all the state universities of the country, and the latter a score or so of our foremost universities, both state and endowed. Perhaps the position of the Association of American Universities would be more accurately described if I stated that its desideratum is a minimum of two years of college work as a basis for professional work, and that some of the institutions embraced in that association would prescribe even a longer time. The important point is that both these organizations, which include all the leading universities of the country, demand that at least two years shall be spent on liberal education before undertaking professional education or specializing with a view to it. I am myself in hearty accord with this program. I should like to see our schools of medicine, law, and engineering reorganized with reference to it. And I am glad to say that a movement of that kind is now in full force in our schools of law, and especially in our schools of medicine. While Johns Hopkins in 1893, Harvard in 1900, and Cornell in 1908, demanded a degree in arts or science of students in medicine, a score or more of medical schools now require two years of college work, and about the same number now require, or are soon to require, one year of college work which shall include the courses in physics, chemistry and biology.

So far as this latter group is concerned, the requirement of a year of college work is probably due to the necessity of providing satisfactory instruction in physics, chemistry and biology. But as this departure breaks with the traditional high-school requirement for admission to the medical course, it prevents the high schools from continuing to be feeders of the medical colleges, and yet it does not establish a preliminary education sufficiently high to command the confidence and the patronage of college men. The chances are, therefore, that this arrangement will prove only a provisional one, and the institutions which have adopted it will either rescind their action and re-establish their connections with the high schools or prescribe a preliminary education of two years in arts and sciences, with a view to attracting the patronage of college undergraduates. It has not, I think, been sufficiently considered that when a medical college once severs its educational connections with the high schools it may so far as the effects on attendance are concerned almost as well prescribe two years of college work as one, and pretty nearly as safely three years as two.

Another service which the universities should render to the medical college is the determination of the question, What subjects of study should enter into the education of prospective physicians and surgeons? Assuming, that is to say, that candidates for the medical degree will have at least two years of study in a college of arts and sciences, the question is, What subjects shall they study? The criterion in answering this question should undoubtedly be the requirements of a liberal education. And it frequently happens that in the case of a professional subject like medicine the requirements of a liberal education in arts and sciences coincide to some extent with the scientific conditions which the medical profession would like to see fulfilled before students enter the medical college. I believe that a perfectly satisfactory adjustment of the problem can be worked out along these lines. I am well aware that this has not been the prevalent point of view. On the contrary, we have had two extreme positions more or less contradictory, which seemed to exclude a middle ground on which educators and medical men might alike agree. These two conflicting views have been voiced by the advocates of liberal education on the one side and of professional education on the other. The former have been in the habit of insisting that an A.B. degree should be a condition of admission to a medical college without much regard to the subjects embraced in the A.B. curriculum, provided only that a liberal education might be claimed on the basis of that A.B. degree. I believe that the underlying desideratum of these advocates was a classical education.

Opposed to them stood the other party made up mostly of medical men who insisted that an A.B. course in itself was of very little value as a preparation for medical studies. What they desired was a preliminary education in the pure sciences: physics, chemistry, biology, comparative anatomy, etc., on which the medical sciences were based. Between these two schools there has in the past been little agreement. But I believe that the time has come for a satisfactory adjustment of the problem.

I have already stated that the foremost educators today agree in demanding that the first two years of the college course shall be required of students who intend to enter such professional schools as law and medicine. These educators, furthermore, have in the course of the last two years come to a pretty close agreement as to the content of the curriculum of these two years of college study. They are agreed that it should embrace English, history, economics, one or two foreign languages, and mathematics, and one or more of the following sciences: physics, chemistry, biology, geology or botany. Such a curriculum furnishes the prospective medical student not only with subjects which are requisite to a liberal education, but also with subjects which form the best preparation for the subsequent study of medicine. Do you ask me what studies I would prescribe for this prospective medical student? I answer at once the English language and literature, French and German, history, economics, advanced algebra and trigonometry, and chemistry, physics, and biology. To these I would add a subject which I never see mentioned by advocates of either of the extreme positions I have already described. I mean the important subject of the study of the mind, and more particularly those aspects of it which are embraced in the modern science of experimental psychology. Considering the close relation between mind and body and the dependence of some diseases on mental conditions, I am often amazed that medical men fail so completely to realize the importance of the study of the sciences of mind as a part of that curriculum of the preliminary education they lay down for prospective students of medicine. I believe that in the first two years of a college course there is time to include psychology with the other studies in liberal arts and sciences which I have already specified. And I do not hesitate to assert that a young man who has received a thorough training in these subjects may, on the one hand, be regarded as a liberally educated man, and, on the other, as scientifically qualified for admission to a medical college and the successful study of the sciences prescribed in the first year of the medical curriculum.

The last service I shall mention which a university could and should perform for a medical college is to provide it with capable and devoted teachers and investigators imbued with the spirit of research. I do not think that the medical profession, and I am sure that the general public does not realize the nature of the change which the advances in modern science make necessary in the faculties of our medical schools. In the commercial and private-enterprise medical colleges, a number of practicing physicians and surgeons came together and devoted the fag end of their time to the instruction of students in medicine. Not only were these men not scientifically prepared for the task they assumed, but their interests lay in the practice of their profession, and the one object they had in view in establishing a medical school was to enlarge their medical practice and make it more lucrative. Now the authorities of our universities know that we cannot have efficient teachers and fruitful investigators, first, unless they are thoroughly trained for their work, and, secondly, unless they devote thei ime and energy to that work. The staffs of lleges are sadly in need of reorganization nce of this criterion. If our medical col- nk *with other colleges in the university,* e because the teachers and investigators on s aff bring undivided hearts to their work and render the same whole-souled service. It is practically impossible for a man to have a large and successful practice and to be *at the same time a scientific and efficient* teacher and investigator in medicine. I lay it down, therefore, as a first condition for the elevation of our lleges, that their chairs shall be filled by nvestigators of the highest scientific stand- e their entire time and energy to the work and investigation. There is no difficulty ing this criterion to the professorships represented by the first two years of the medical curriculum—to subjects like anatomy, physiology, biochemistry, pathology, bacteriology, etc. I recognize, however, that there is a difficulty when we come to the professional and practical branches embraced in the last two years of the curriculum—medicine, surgery and obstetrics, not to speak of the minor specialties. Yet I am confident that it is impossible, under the present system of appointing to these subjects distinguished practitioners who continue in unrestricted practice, to produce satisfactory results in the work of instr vice I investigation in these fields. I recogr that was inclined to that men are no' ation by establishing a medical obstetrics, childre be the single word: *don't.* Institu- unless they ion is as unhallowed a motive for the multiplication of medical colleges as the love of personal gain. The latter motive has filled the country with commercial schools of medicine. These schools are a disgrace to our country. Starving medical departments of impoverished universities are equally disgraceful. And the supposed glory accruing to a university which institutes professional schools when it has no funds to maintain them is as dishonorable a motive as the gain in professional advancement sought by physicians and surgeons who establish and maintain the private-enterprise medical institution.

The first service, therefore, which universities may *render to medical* education is a negative one. But, though negative, it is fundamental and vital. Have done with sham in medical education! Recognize that a medical department is the costliest depart of a university! There may be a first-class univ th- content with their evenings or even with their afternoons. Teaching and investigation demand not only their best powers, but their best powers when they are fresh and capable of their highest exercise. Keeping this consideration in mind, I would suggest that their forenoons might be devoted to the work of the medical college. And if the rest of the day were devoted not to general practice, but to consulting practice, or to practice in a hospital owned or controlled by the medical college, we should have the best solution of the problem I can think of at the present time.

I have been speaking of the services which a university can and should render a medical college. I have spoken also of the unsatisfactory condition in which much of our medical education is at the present time. But I cannot conclude without calling attention to the enormous progress which has been made in the last few years, and I want finally to express my own belief and conviction that there is no subject embraced in the purview of our universities in which such rapid progress in recent years has been made, both in instruction and investigation, as in medicine, and there is no subject in which I look toward the future with more hopefulness and confidence of results, great, fruitful, and beneficial to mankind.

THE ADMISSION RATE FOR TUBERCULOSIS AMONG MERCHANT SEAMEN DURING THE PAST TWENTY YEARS

G. B. YOUNG, M.D.
Surgeon, U. S. Public Health and Marine-Hospital Service, Assigned to U. S. Marine Hospital
CHICAGO

The figures presented herewith will, I think, be a surprise to many people, even to some of the medical officers of the Public Health and Marine-Hospital Service who have been active in bringing about the result which *the figures indicate. A few words of explanation are* necessary before the figures themselves are presented.

In 1893 Passed Assistant Surgeon J. O. Cobb of the service contributed to the annual report of Surgeon-General Wyman a strong plea for the establishment of special hospitals for the care of tuberculous seamen. The following year Passed Assistant Surgeon Bratton submitted a very strong plea for the same action. Surgeon-General Wyman took up the plan at once and quickly secured the use of the abandoned military reser- gation at Fort Stanton, New Mexico. The original plan gener. Cobb was to have two sanatoriums, one on the At- trainin in North Carolina mountains, and one in Califor- leges and' funds, together with the theory, much equipped to supply a dozen years ago than now, that thorough training idy did better in the arid Southwest physiology, physiologi the opening of one general sana- ogy, and bacteriolog on.

be added a readin reason for the establishment of the which is an al the fact that under conditions as they man, it will patients who got well enough to demand good train rges went at once aboard ship, *to spread the* certain a among their shipmates and again to break I hav emselves under the strain of their occupation medic e stress of their unfavorable environment. The alone ases remained in hospital and were comparatively mer nless, except in the smaller hospitals where they ar not b ut in wards by themselves.

ll this was that the patients who should chance for recovery not only lost it, neans of actively producing other cases. Moreover, the patients were averse to entering hospitals, and as long as they could get about preferred to come at long intervals to our out-patient dispensaries, as the figures to be here presented clearly show.

It was believed that by sending the favorable cases to Fort Stanton they could not only have a better chance for recovery, but, what was much more important, they would lessen the active foci of infection among their fellows. At first only selected cases were to be sent, but this was rather vague, as individual medical officers naturally differed a good deal both as to their prognostic skill and as to the appeal of the purely humanitarian side of the matter. The proportion of those sent to Fort Stanton has steadily risen, however, reaching 56.4 per cent. in 1908.

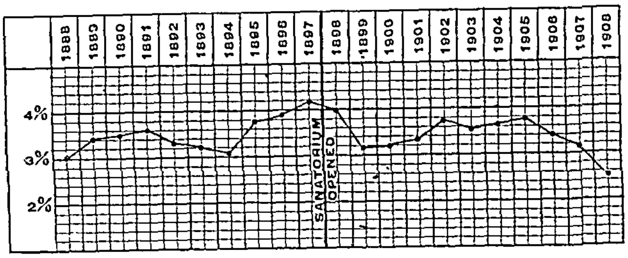

Chart 1.—Percentage of admissions for tuberculosis 1889 to 1908. Total admissions to hospital for all causes were 270,210. The average annual total was 12,867.

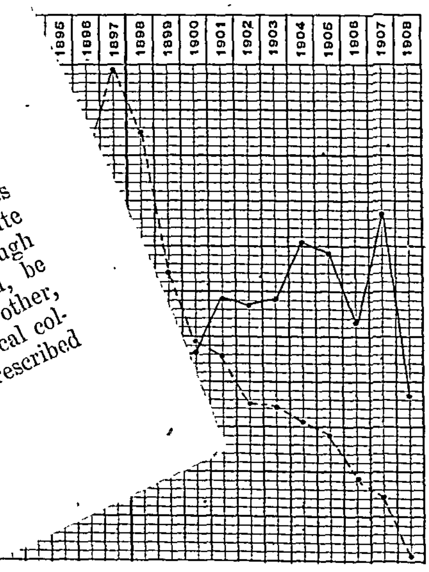
The sanatorium was opened in 1897, but only in a small way at first, so that the close of the fiscal year 1908 practically marked the end of the first decade of its existence. I have, therefore, taken the figures for the past twenty rs, ten before the policy of segregation was begu n since.

D time there were 270,210 patients marine hospitals for all causes; the annual admissions ranging, in round numbers, from eleven to fifteen thousand. These figures are large enough to amount to something, and their value is enhanced by the three factors which give peculiar value to all the admission statistics of the marine hospitals, viz.: The beneficiaries of the service are practically all adult males, from 21 to 50 years of age; the diagnoses are all made in strict accordance with an official nomenclature, and the figures are recorded and tabulated in all the hospitals in accordance with a uniform system.



.elation between numbers of out-patients (dotted line) .spital admissions (solid line). The heavy vertical line in .ter indicates the date of beginning the policy of segregation.

To make the figures truly contrasting I have omitted the figures from the insular stations not existing prior to 1898. The following table shows the percentages of admissions for tuberculosis during the twenty years, and Chart 1 shows the same thing graphically:

TABLE 1

Year.	Percentage of Admissions for Tuberculosis.	Year.	Percentage of Admissions for Tuberculosis.
1889	3.42	1899	3.18
1890	3.47	1900	3.15
1891	3.67	1901	3.30
1892	3.33	1902	3.66
1893	3.20	1903	3.57
1894	3.08	1904	3.64
1895	3.79	1905	3.78
1896	3.90	1906	3.40
1897	4.19	1907	3.15
1898	3.98	1908	2.53

At first glance one would say that the figures represented an almost complete failure to secure the result aimed at. The rate for 1908 is only 1.19 per cent. less than that of 1889, while it is only 1.64 per cent. less than the rate of 1897, the year the sanatorium was opened. The real result is seen, however, when we compare these figures with those of the out-patient records.

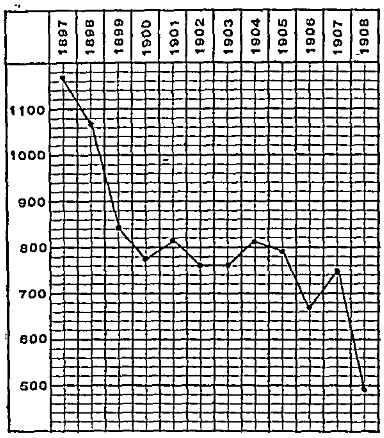


Chart 3.—Total admissions for tuberculosis (out-patients and hospital patients) since policy of segregation was initiated.

I therefore present Table 2, which shows the totals of out-patients treated for each of the twenty years, the admissions to hospital for the same years and the total in each case:

TABLE 2

Year.	Out Patients.	Hospital Patients.	Total.
1889	543	437	980
1890	605	474	1079
1891	547	529	1076
1892	526	500	1026
1893	376	443	819
1894	465	395	860
1895	654	457	1111
1896	592	469	1061
1897	696	475	1171
1898	625	439	1064
1899	470	376	846
1900	395	383	778
1901	376	441	817
1902	329	438	767
1903	321	441	762
1904	304	502	806
1905	293	496	789
1906	247	418	665
1907	222	533	755
1908	157	342	499

This shows that the total admissions in 1908 are only 46.7 per cent. of what they were the year before the segregation was begun. Now, of course, it would be absurd to claim that the present policy alone has resulted in more than cutting the rate in two. The fact is, course, that there was formerly much duplication, both by admission of patients to hospital who had previously been treated as out-patients and the readmission of hospital cases, and by out-cases being treated at different places. To what extent these readmissions would reduce the totals shown ten years ago it is impossible to say, but the figure was very considerable.

On the other hand, there is not the slightest doubt that admissions for all causes are now examined much more critically for signs of tuberculosis than was done fifteen years ago. I know that at the Marine Hospital in Chicago a very respectable per cent. of men recommended for transfer to Stanton have been ones seeking admission for various causes, medical and surgical, and found to have incipient tuberculosis. There can be no doubt that we are now diagnosing much more nearly all the tuberculosis presenting itself than we formerly did.

This increased accuracy of diagnosis compensates for a good many of the readmissions under the old order of things, but, assuming that there remain 20 per cent. of the readmissions to account for, a very liberal estimate, we would still have the astonishing and gratifying result that we have reduced the amount of tuberculosis among the beneficiaries of the service at the present time by more than 25 per cent. as compared to what it was when the policy of segregation was begun. Unquestionably this has been due to having eliminated very largely the chance of the active, walking cases infecting their mates board ship. If we could send all the out-patients to ospital, even if we only transferred to Stanton the 56 per cent. sent last year, we could doubtless in five years make a more striking reduction, but for several reasons this is difficult to do. That it can be closely approximated, however, if care is taken to fully explain the matter to the men themselves, is shown by the experience in Chicago, where we have had only three out-patients treated for tuberculosis in the past two years.

The change brought about in the relation between out-patient numbers and the number of hospital admissions, as well as the total cases, is strikingly shown in Chart 2.

Chart 3 shows the result of combining the total figures, and it shows, I think, that the Public Health and Marine-Hospital Service has a right to claim a very notable accomplishment in the direction of securing a decrease of tuberculosis among the merchant seamen.

THE EARLY DIAGNOSIS OF RENAL TUBERCULOSIS *

DEAN LOREE, M.D.
Clinical Professor of Genito-Urinary Surgery, University of Michigan
ANN ARBOR

No more striking instance of concerted action against disease by the combined efforts of the profession and the laity has ever been seen in this country than the war that is at present being waged against tuberculosis. The line of battle is being directed against the pulmonary form of the disease because this is its stronghold and the focus from which other organs become secondarily infected.

In the second annual report of the Phipps Institute of Philadelphia, an institution established for the prevention, treatment and cure of tuberculosis, may be found a resumé of the autopsy findings in sixty cases of advanced pulmonary tuberculosis, of which number thirty-five showed unmistakable evidences of renal involvement. It is hardly necessary, however, to repair to the tabulations of our large hospitals for a knowledge of the frequency of the disease in individual organs, because tuberculosis is always with us and there is no community that does not witness it in many of its varied forms.

The curability of phthisis in a majority of the early cases receiving proper attention is a well-established fact. With the advent of more positive means of diagnosis, the recognition of the incipient stage of tuberculosis in the kidney has become an added responsibility on the profession.

Albarran has well said: "The early diagnosis in renal tuberculosis is the key to success in its treatment." There are certain somewhat vague signs occurring early which it is essential to observe in order to bring these patients under proper environment in time for favorable results in their management. Especially is this true for practitioners removed from laboratories and unacquainted with the more precise methods of those more favorably situated for the study of the disease.

The disease at its beginning is characterized by an absence of symptoms on the part of the kidney, but in a majority of instances manifests its presence by vesical irritation. Because of these facts the earlier writers drew the erroneous conclusion that the bladder was primarily the seat of infection. More recent investigation, aided by the ureteral catheter, has proven its hematogenous origin.

The cases of patients presenting themselves to the physician because of frequent, painful or burning micturition without definite origin should at once excite suspicion, no matter how short the duration of the attack, and should call for a very thorough physical examination of the entire body, and especially of the lungs, the testicles, the epididymis, the seminal vesicles and the prostate. When early symptoms exist in the kidney region they are of little value, as slight pain and enlargement may mean only hypertrophy of the sound side. If the patient is a female a vaginal examination should be made in the attempt to find a thickened ureter. Fenwick of London attributes great diagnostic significance to this sign if combined with a displaced and retracted ureteral orifice, as seen through the cystoscope.

Much may be gained of diagnostic value from the cystoscope in the hands of those skilled in its use, and the localization of the disease is only possible by ureteral catheterization. Under the most favorable circumstances these procedures are difficult and many times rendered impossible by disease processes. At the onset of the irritation the bladder mucosa is much congested, the vessels cannot be outlined, bleeding is easily caused and flakes of pus that cannot be washed away cling to the walls. Ulceration supervenes, and if the condition is unilateral ulcers may be found, either single or multiple, about the ureteral orifice of the infected side. The mucosa, having lost its original color, becomes a dull gray and thickened to such an extent that the ureteral orifices become buried. If unchecked the inflammation extends to the musculature of the bladder, causing thickening of the walls, trabeculation, sacculation and sufficient contraction to render its capacity too small for sufficient media to allow investigation. The very early cases may show marked pathologic changes in the bladder mucosa, hindering many times the rapid catheterization which is essential if we are to guard against carrying the infection to fresh soil. If the catheterization cannot be accomplished easily and with the least possible manipulation of the cystoscope, it should be deferred until such time as the bladder may have been rendered sufficiently clean by daily irrigations.

---

* Read before the Northern Tri-State Medical Association (Michigan, Ohio and Indiana), at Fort Wayne, Ind., Jan. 11, 1910.

When the bladder involvement is more or less superficial it shows a strong tendency to heal without further aid than the removal of the kidney focus. The more persistent conditions call for heroic treatment, as they are many times the cause of more anxiety to both patient and physician than the original focus of the disease. After having discontinued the use of carbolic acid because of the pain incident to its application, I have resumed its employment with modifications. Instead of using 50 c.c. of the aqueous solution of carbolic acid, as advised by Rovsing, I find that the pain and collapse will not be encountered if smaller amounts are at first used, allowed to remain in the bladder but a few seconds, and the excess that may have clung to the walls washed out with a 30 per cent. alcohol solution. In this way a tolerance will be secured and the full amount may be employed later.

The positive diagnosis of renal tuberculosis is dependent on competent bacteriologic and chemical examination, and necessitates laboratory facilities and a knowledge of cystoscopic technic. In the most expert hands tubercle bacilli can be demonstrated in 75 to 80 per cent. of the cases. The sample of urine sent to a laboratory should not be less than three ounces. It should be drawn through a sterile catheter into a sterile bottle after having carefully cleaned the external parts. After several failures to find the organisms by the staining methods in vogue, resort must be had to the inoculation of guinea-pigs. While bacteriuria without a kidney lesion is not common, it is a possibility, rendering the demonstration of the bacilli in the absence of pus of little diagnostic significance. Tuberculin may be employed as a diagnostic aid, but as a matter of fact it has little value when compared with the laboratory methods. During the delays incident to the laboratory investigation and the return of reports, the bladder should receive daily irrigations to aid in the removal of inflammatory products constantly being poured into it from above, thus aiding materially in the localization of what might become an interstitial inflammation in the mucous membrane of the bladder.

With few exceptions it may be stated that a unilateral renal tuberculosis with the opposite kidney showing sufficient function calls for nephrectomy, but many of the patients entering the hospital are far removed from the early stages of the malady, and nephrotomy, or the opening of a perinephritic abscess, is many times a measure which must be resorted to for the saving of life. Many times these are examples of our sins of omission and a strong plea for the early recognition of the disease and the removal of morbid processes.

However, I cannot agree with the more or less widespread opinion that in the early stages and under the conditions above cited the kidney must inevitably be removed. Post-mortem examinations many times disclose healed tubercles of the kidney as well as of other organs. Complete cures are at times shown in cases where the existence of the disease was easily demonstrable. I have recently had the opportunity to follow a case that very aptly illustrates my point.

History.—A female patient, 22 years of age, consulted me in July, 1909, for frequent and burning micturition. She was very emphatic in her statement that it had been of only two weeks' duration, and that she had never experienced the trouble before the present attack. A bacteriologic examination of the urine from the bladder contained tubercle bacilli, and the subsequent samples obtained by ureteral catheterization revealed a right unilateral infection with the opposite kidney normal. The sediment of the urine from the right side also contained pus-cells, but no other organisms. Because of the short duration of her trouble, coupled with the fact that the patient had financial support sufficient to procure for her the most favorable environment, I did not advise operative procedure, but sent her to a cool climate for the summer, where she lived out of doors both night and day. She also had a sufficient and well regulated diet and received daily bladder washings, with the injection of a 2 per cent. solution of iodoform in sweet oil twice a week. She returned to me in October having gained twenty-one pounds in weight, her cystitis was cured and her urine showed an absence of both bacteria and the products of inflammation.

While I am well aware that the kidney in her case may harbor a latent infectious process, I think no one could at the present time advise its removal, more especially as the patient is a member of a family of more than average intelligence and has been advised of the possibility of a recurrence and the consequent necessity of surgical measures. Such methods are only applicable in selected cases, in which the most favorable conditions are obtainable; nor should the expectant treatment be persisted in if beneficial results are not immediate. As the means for earlier diagnosis in renal tuberculosis become more common there will be more cures without operation reported, and more rapid results will be obtained by local application of remedies to the kidney pelvis.

A STUDY OF THE EYE IN MENTAL DEFECTIVES *

L. PIERCE CLARK, M.D.
AND
MARTIN COHEN, M.D.
NEW YORK

It is difficult to understand why the fundus examination in idiocy has been so little emphasized. Probably the examination of the fundus in such cases, being so extremely difficult, may account in part for the lack. Possibly the negative findings of Moss[1] have also deterred some from the study. He examined 116 feeble-minded children in Berlin. The study showed but 2 cases with alteration in the fundus. His cases, however, were not drawn from the low-grade idiots.

The much more careful work of Gelfe[2] on 578 cases throws more light on our subject. His cases comprised (1) 192 mentally backward boys and 192 girls of the same class; (2) 25 boys and 21 girls who were weak-minded (feeble-minded of our designation) and 47 boys and 30 girls who were unteachable imbeciles (imbeciles of our classification), and, finally, 42 boys and 28 girls of the low-grade idiots. All the cases were examined in the institute for mental defectives at Berlin. But 27.5 per cent. of all Gelfe's cases showed normal eyes. These results are quite in accord with our findings. Gelfe's idiots showed a percentage of 43 for normal idiot fundi as compared with 56 for weak-minded and 83 for simply backward children.

Many writers concern themselves with functional imperfections only in examining for visual defects in the mentally deficient child, which accounts for the apparent discrepancy of data. It may be said in passing that there seems to be unanimity of opinion that eye defects are much more frequent in mentally defective children, and that these defects react in further crippling the child's mental development.

[2] Gelfe, T.: Relationship between Visual Organ and Feeblemindedness (Karlsruhe), Samml. a. d. Gebiete d. Augenh. Hälle a. S., 1904.

Our study of the eye in the mentally defective child was undertaken with a twofold purpose:

1. From studies made in 1907 by Clark and Tyson[3] into the nature of the eye changes found in dementia præcox it was shown that a fairly constant eye syndrome was present in that mental disorder, embracing, among other signs, a mild grade of optic nerve degeneration, which was thought to be of autotoxic origin. In the numerous discussions of the paper held before various societies on the occurrence of the optic nerve changes in dementia præcox, it was thought that the syndrome was due more to a strong tendency to neural degeneration in the precocious dements than to a particular autotoxin, and that careful examinations into the allied states of mental degeneracy so ideally presented by such conditions as imbecility or idiocy ought to throw light on this phase of the subject. And, indeed, it has. Fully three-fourths of all cases of idiocy of our present study show varying degrees of a retrobulbar neuritis of a degenerative character.

2. The second object of inquiry was to note the presence or absence of pathognomonic structural defects in the eyes of feeble-minded and idiots comparable with the other grosser mental and physical defects so well known. The negative findings on this second part of our study have been disappointing. It would seem that the eye defects in idiocy do not usually extend beyond those of mere functional incompetence of vision. Moreover, the defective central innervation may explain the lack of visual acuteness, in defect of attention, as well as defect in perception of color, etc.

Our study was made in our Randall's Island service, which gives a range of more than 1,000 cases to select from. Although 150 cases were selected, but 129 patients could be examined carefully. Fifty cases, each, of feeble-mindedness, imbecility and idiocy were chosen. The patients of the feeble-minded class were of the highest teachable grade. Those of the imbecile class were of the non-teachable grade, but able to care for themselves and do simple tasks about the wards, while those of the idiot class were the lowest types of helpless cases in the entire service. Only idiopathic cases were studied.

Changes in external examination of the eyes were found in but few patients; unilateral ptosis was noticed in two feeble-minded children and in one idiot. Strabismus was found in one feeble-minded child. The pupillary reflexes to light, accommodation, etc., were present in all, but sluggish in the idiots. There was rigidity of the pupils in one idiot. The acuity of vision, the fields of vision and the refractive errors could not be determined, owing to lack of accurate cooperation because of mental defect. By means of retinoscopy there were found 4 cases of myopia of high degree, 3 of hypermetropia and 15 of astigmatism of various types.

The ophthalmoscopic examination was made by Dr. Cohen by means of the indirect method, with a candle as the source of light; complete mydriasis was obtained by the use of atropin sulphate solution. In only 106 of the 129 could the fundi be properly examined.

Feeble-Minded.—But 9 of the 29 examined showed normal fundal appearances. Pallor of the temporal half and edema of the nasal half of the disc were present in seven cases. Two patients showed slight indistinctness of the disc and one well-marked neuritis. Evidence of an early stage of atrophy (as shown by pallor of disc) was found in 6 cases. In none was there advanced atrophy present. Dilatation of veins was seen in four patients.

Imbeciles.—Of the 24 examined there were 15 in whom the eyegrounds were normal in appearance. Only 4 patients of this group showed pallor of the temporal half and edema of the nasal half of the disc. Slight indistinctness of the disc was present in one patient. Pallor of the disc was seen in these cases. One patient showed well-marked atrophy.

Idiots.—Normal fundal appearance was present in but 2 of the 53 cases of this group. Temporal pallor and nasal edema were seen in 13 cases. One showed general congestion of the entire disc, 8 presented a generalized pallor of the discs. Optic atrophy was present in 3 cases; the veins were dilated in one. One patient, each, showed choked disc, thrombosis of the central vein, retinal congestion, retinal hemorrhage.

No specific cause can fully account for the degenerative changes which we have noted in the optic discs of idiots. It is not necessary or desirable to review in detail the considerable literature of pathogenesis of idiocy. It is doubtless likewise unnecessary to say that, after all possible causes of idiocy have been considered, a very large number of idiots remain unaccounted for. We are content at this time to call attention to the fact that in the majority of the cases idiocy is attended by fairly constant and definite changes in the optic nerve.

In conclusion, it may be said that our study shows there is probably a well-marked tendency to neural as well as psychic degeneration in the great majority of all grades of idiots. The research is submitted as a contribution to the clinico-pathologic study of idiocy and degeneration.

CONGENITAL SACROCOCCYGEAL CYST OF EPENDYMAL ORIGIN

GEORGE G. DAVIS, M.D.
Associate in Surgery, Rush Medical College
CHICAGO

Although it is the primary purpose of this paper to report a case of congenital cystic tumor occurring in the sacrococcygeal region, a few words regarding the general subject of tumors situated in this locality will help to make clear the pathogenesis of this case. Therefore, after considering the general classification of sacrococcygeal tumors and reviewing the cystic type in some detail, the embryology of the caudal end of the human embryo will be considered before taking up my case.

The congenital dorsal-sacral hernia containing bowel and bladder must be considered in connection with tumors of this region. Lotzbeck[1] gathered from the literature 6 such cases, which he divided into simple and combined cases. Under the heading of simple he cites three cases: two were hernias of a part of the bowel with a normal sacrum, reported by Bezold[2] and Schreger,[3] respectively, and one case of hernia of a part of the bladder with a normal sacrum, reported also by Schreger. Under the heading of combined cases he cites also 3 cases: one a dorsal hernia combined with a cyst, in which case the sacrum was normal, reported by Meinel,[4] and 2 cases with defective sacrum; one reported by Schmidt[5] in connection with a cystic tumor and absence of the sacrum, and another reported by Stafford[6] in combination with a spina bifida.

[2] Bezold, von: Sammlung seltener chirurgischen Beobachtungen und Erfahrungen, Arnstadt, 1812.

[3] Schreger: Chirurgische Versuche, ii, 164, etc.

Analogous to the bony defects and accompanying complications found in the cervical, dorsal, and especially in the lumbar region, we note that spina bifida, both anterior and posterior, and spina bifida occulta, with meningocele and myelomeningocele, are likewise to be reckoned with in the classification of tumors of the sacrococcygeal region. Nieberding,[7] in an excellent article, has collected 9 cases with anterior sacral meningocele. Lotzbeck also reports 9 cases of congenital hydrorachis in the sacral region, 3 of which were without spina bifida and 6 with spina bifida. These have been confused with another group of tumors, the genesis of which is yet but little understood, although histologically they are readily classified as cystic lymphangiomas, angiosarcomas or peritheliomas (coccygeal gland?) and simple lipomas. A combination of the former (meningocele, etc.) with the latter (lymphangiomas, lipomas, etc.) is also found and deserves special classification according to von Bergmann.

Aside from these hernias and spinal defects and neoplasms, such as lipomas and lymphangiomas which have no character peculiar to this region, the congenital pathologic productions of the sacrococcygeal region may be classified according to the more modern authors (Herrmann and Tourneux,[8] Tillmanns,[9] E. von Bergmann,[10] Stolper,[11] Marchand,[12] Borst,[13] Calbet[14]) into four principal groups: the caudal appendages, the dermoid cysts (pilonidal cysts and sinuses), mixed tumors and fetal inclusions.

I. CAUDAL APPENDAGES

The caudal appendages are of two types: the pseudo and true tail formations. The pseudo-tails are devoid of vertebræ and are due to the abnormal persistence and hypertrophy of the caudal filament (Herrmann and Tourneux[8]), or they may be formed in some cases by lipomas which have simulated the shape of a caudal appendage. The true tail formations (Förster[15]) consist of new growth of bone and cartilage or are prolongations of the sacrum.

II. DERMOID CYSTS

The sinuses and simple dermoid cysts, or pilonidal cysts, so called from the fact that frequently they contain nests of hair, occurring in the median body line, between the buttocks at lower end of sacrum and coccyx, though congenital, are often first noted during early adult life after irritation or inflammation has called attention to this region. Various theories have been advanced to explain their genesis. Hodges explained them as congenital dimples, being filled in by hair rubbed off from the body; the dimple being due to imperfect union of the lateral halves of the body. Féré thought them due to incomplete closure of "posterior umbilicus," meaning the lower end of the medullary canal. Lannelongue assumes that there is an extension inward of the skin which is bound down to the coccyx. Mallory,[16] to study this condition, made microtome sections through the sacrum and coccyx of embryos at various ages. He says:

> These cases show that in fetuses of three to six months there is very frequently present over the coccyx, a canal lined with epithelium, in some cases connected with the skin, in others not; in some situated near the skin, in others near the coccyx. It seems much more likely that they are due to incomplete obliteration of a former canal, and extending as they all do upward and posteriorly to the coccyx, the medullary canal seems the most likely origin.

Tourneux and Herrmann[17] had earlier noted these epithelial rests of the medullary canal (*vestiges médullaires coccygiens*) which contracted adhesions to the deep layers of the skin, but explain the dimple or *fossette coccygienne* as due to the traction, during downward growth of coccygeal end of vertebral column, by the caudal ligament, which is a bundle of fibers connecting the *vestiges coccygiens* to the extremity of the coccyx. The anatomic facts which Tourneux and Herrmann presented in 1887 in support of this mechanical explanation have been confirmed by Ernst Unger and Theodor Brugsch.[18] Further reference will be made to this subject in the discussion of the embryology.

III. MIXED SACROCOCCYGEAL TUMORS

The mixed tumors (cystosarcomas, etc.) of the sacrococcygeal region present a very complex structure and have been found in the following formations (Herrmann and Tourneux, Lotzbeck, Borst and others); cysts of more or less voluminous size, the simple or stratified epithelial lining of which is essentially polymorphous and may or may not have cilia; epithelial masses of glandular aspect; cartilaginous or bony masses; smooth and striated muscle fibers; masses of nervous substance; the whole distributed without any apparent order in a framework of connective tissue.

These tumors, according to Borst,[19] Herrmann and Tourneux,[8] von Bergmann,[20] Braune,[21] Lotzbeck,[1] result from the abnormal hyperplasia of a group of organs, belonging to the subjects which carry them. They are monogerminal—that is, they have arisen from a single impregnated ovum and the cysts and neoplastic masses result from developmental errors, excessive hyperplasia of one or more elements, ectopia of contiguous tissues and similar errors in development. It appears very probable that the various transitory organs are able to give birth, each to that which concerns it, to the neoplasms, the origin of which will be indicated by the analogy of their histologic composition. These transitory structures are: (a) the caudal medullary tube (*les*

life the medullary tube is prolonged to the end of the vertebral column, and at the last vertebra it is curved backward and becomes adherent to the deep layers of the skin. And at the end of the third month by the more rapid growth of the vertebral column than that of the soft parts, the portion of the medullary tube adjoining the vertebræ is dragged down with it and as the reflected portion remains attached to the external integument a curve is described by the neural axis, the branch of which that is in relation to the dorsal surface of the coccygeal vertebræ is termed the direct coccygeal segment (*segment coccygien direct*) and the portion directed upward and backward is termed the reflected coccygeal segment (*segment coccygien réfléchi*). In the fourth month the direct coccygeal segment atrophies and disappears, but the dorsal or reflected segment continues its evolution, and it is to the cellular masses constituting this segment that the authors apply the term *vestiges coccygiens* of the medullary tube. These medullary coccygeal vestiges attain their maximal development during the fifth month, when they are composed of masses of small spherical or polyhedral cells having an irregular cavity lined by a layer of prismatic polyhedral or pavement cells. These are attached to the extremity of the coccyx by bundles of laminated fibers, the caudal ligament. From the sixth month of fetal life the *vestiges coccygiens* undergo progressive atrophy. Nevertheless, rests or remnants of them may be found at the time of birth. In the growth of the soft parts which force the cutaneous coverings backward, the skin situated in relation to the "coccygeal vestiges" remains fixed at the point of the coccyx by the caudal ligament. In certain cases this ligament does not yield to the extension of the neighboring parts and the skin invaginates and constitutes an infundibular depression more or less deep (*fossette coccygienne*). The wall of this depression is lined by the cutaneous covering, devoid of hair follicles, but containing sudoriferous glands in abundance. It is thus that cysts of the second type or dermoid cysts (pilonidal cysts) are formed in the sacrococcygeal region.

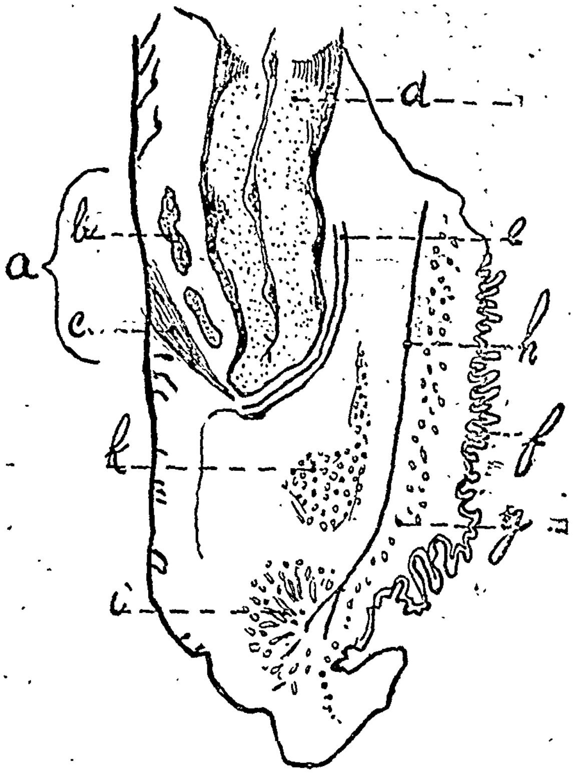

Fig. 3.—Sagittal section of caudal end of human female fetus of 16 by 23.5 cm. Enlargement 8.5/1 (from G. Hermann and F. Tourneux, cited in Note 8); a, "glabelle," surrounded by hair follicles; b, paracoccygeal medullary vestiges; c, caudal ligament; d, coccygeal vertebræ; e, caudal vein (anterior) and artery (posterior); f, mucosa of rectum; g, internal sphincter; h, longitudinal muscular layer of rectum; i, external sphincter; k, levator ani.

REPORT OF CASE

The following history I obtained Sept. 17, 1909, at the Central Free Dispensary (case No. 16118) of Rush Medical College in the department of surgery:

Patient.—Baby L. L., aged 7 days. When the child was born a swelling the size of a man's fist was noted in the perineal region. At birth the skin was smooth and white and of quite normal appearance. The swelling enlarged after birth and the skin took on a blue color. The grandmother, who brought the child to the dispensary on account of the swelling, mentioned no other defects or untoward symptoms. Urination and defecation were not interfered with. Father and mother were both living and well. The mother had had no miscarriages. This was the third child; the other two were strong and healthy and were 4 and 2 years old respectively. The birth of this child was normal; head presentation and no instruments used and no difficulty experienced in delivering the buttocks with the attached swelling.

Physical Examination.—The child was well nourished, strong and appeared healthy. The head was of normal size and fontanelles not enlarged. Eyes, nose and mouth were negative, as were also the chest and abdomen. The arm and leg movements were free and there was no sign of paralysis. From the right gluteal region protruded a pedunculated or rather sessile tumor almost as large as the baby's head. This growth extended from the gluteal fold below to the notch between the coccyx and gluteal muscle above, and from the greater trochanter laterally, to the median line of the body, where, extending into the perineum, it encroached on the vulva and the anus (Figs. 4 and 5). The skin covering the tumor was in a normal condition and there were no signs of old scars or inflammatory processes; it was smooth and presented no elevations or depressions. The color was white with faint blue tint where the skin was stretched tightly over the fundus of the tumor. At the apex of the fundus was a reddish discolored area the size of a quarter. Tortuous veins were clearly outlined over the surface of the swelling. A linear elevation of skin showed a white cord-like structure coursing over various parts of the swelling subcutaneously. When held to light the swelling was found to be translucent. The mass fluctuated distinctly. The white linear structure described above could be moved under the skin and felt like a piece of wet hemp string slipping under the palpating fingers. Posteriorly the coccyx was very movable and was pushed to the right side by the tumor mass. Above and to the left of the coccyx was felt a mass of cartilaginous consistency which was very movable. The tension of the swelling was not increased when the child cried. When pressure was made on the tumor, the volume of swelling was not diminished, nor were the fontanelles thereby affected, or any disturbances referable to the cord caused by so doing. (No rectal examination was made.) A puncture of the cyst was made for the purpose of diagnosis; an ounce of light yellow, turbid fluid was obtained which gave reaction for albumin and microscopically showed red cells.

X-Ray Examination.—On September 21, when ten days old, the patient was brought again to dispensary and was referred to the *x*-ray laboratory, where two views of the lower portion of the vertebral column were taken, one lateral, and one antero-posterior. The lateral view (Fig. 6) showed no abnormal condition of the spinal column; the cyst was well outlined and no solid contents seen within. The antero-posterior view (Fig. 7) again outlined the cyst and also showed the coccyx pushed to opposite side. There also appeared in the lumbar and sacrococcygeal region a linear area situated to the left side which was not shaded, while on either side of the same shadows were distinctly visible. This picture at first was thought to be of some value in throwing light on the genesis of the cystic swelling; the possibility of a spina bifida anterior with a meningocele was considered. But Dr. Potter, who took the *x*-ray pictures, interpreted the non-shaded area as the place between the two centers of ossification: T, the smaller shadow, being the ossific point of the transverse process and lamina on the one hand and B the larger, the ossific point of the body of the vertebræ. The reason a similar picture was not produced in the opposite side of the body was probably that the child was not lying perfectly straight. Another picture of a normal child ten days old was taken as a control to compare with this, and a somewhat similar condition was found.

Operation.—The patient was referred to Dr. Bevan, who operated on the child (September 29) when 19 days old. Under ether anesthesia two half-moon-shaped flaps, one anterior and one posterior to the tumor, were made, thus avoiding injury to the nerve and arterial supply to the perineum; the skin was readily stripped from the tumor mass and with slight hemorrhage the growth was followed to its insertion about the coccyx, a part of which had to be removed in taking away the mass. Some difficulty was experienced in separating the growth from the lateral wall of the rectum, which was pushed forward by the tumor, which almost filled the pelvis. The skin flaps with plenty of redundant tissue were brought together with silk and horsehair. Instead of the usual gauze dressing a zinc oxid paste was first applied over the sutured surface to protect the wound from infection from feces and urine. During the operation the surface of the sacrum was freely exposed and no bony defects were found. The child made an uneventful recovery.

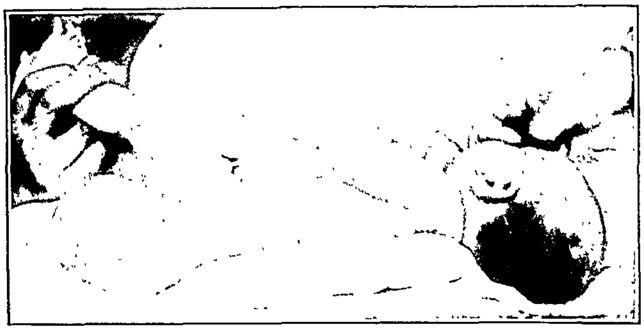

Fig. 4.—Sacrococcygeal cyst, showing extension of the growth downward from coccygeal region.

PATHOLOGIC REPORT

The gross specimen (Fig. 8) consisted of a mass almost the size of a new-born child's head, one half of which was covered with skin; the other presented an exposed area where skin was removed at operation. The mass on palpation felt like a sac full of fluid. At the center of the exposed area (Fig. 8, A) was a piece of cartilage (tip of coccyx) three-quarters of an inch long, one-fourth of an inch wide, and one-eighth of an inch thick, tapering to a point. At the side of the coccyx was an opening to a smaller cyst the size of a hen's egg. The lining of this cyst was smooth, shiny, and white. In the wall of this cyst were four nodules projecting the lining of the cyst forward, also causing an elevation on outer aspect of the cyst. These varied from the size of a BB shot to that of a pea. They were white and of a firm consistency. They cut with slight resistance and on cross-section presented a white homogeneous granular surface. A small cyst the size of a pea, punctured, emitted a clear white fluid. At the base of the attachment of the egg-shaped cyst to the large cyst was an annular thickening of firm consistency which was described in physical examination as a "mass of cartilaginous consistency and very movable." Diameter of base attachment is size of a quarter, the annular thickening itself is about one-fourth of an inch thick.

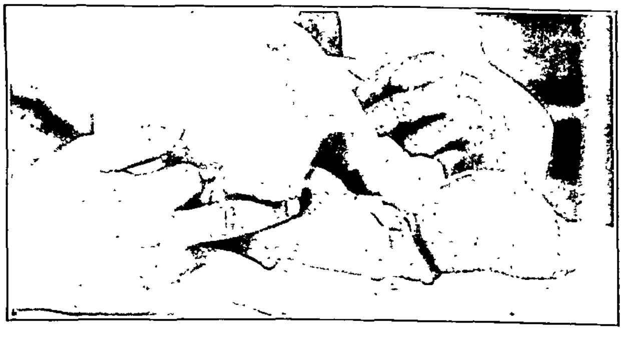

Fig. 5.—Infant lying on its back with legs flexed on its thighs; the tumor mass on the right displacing the anus and vulva.

The main large cyst was punctured (at B, Fig. 8), contents removed and cyst hardened *in toto* in 10 per cent. formalin.

The fluid contents of the cyst amounted to 400 c.c.; were light yellow in color; did not give reaction for the reduction of sugar; 1015 sp. gr.; gave reaction for albumin and showed under miscroscope red and epithelial cells.

The main cyst cut after hardening is shown in Figs. 9 and 10. Between the main cyst and the coccyx (A) were three smaller cysts (C) varying in diameter from one to three cm., the walls of which were thick (2 to 3 mm.) and of firm consistency, and were lined with a smooth and shiny surface. The wall of the large cyst was thin (1 mm.) over the fundus of the swelling, and a little thicker (2 mm.) nearer the coccyx. The skin could easily be separated from the cyst wall. The cavities of the cysts did not communicate with one another. The lining of the cyst was generally smooth and shiny, and presented three points of special interest; first, two nodules, second, three areas of depressed scar like tissue formation, and, third, several string-like growths of a heavy, white, fibrous-like tissue. The nodules (B, Figs. 9 and 10) were the size of split peas, projected beyond the inner surface of the cyst, and had a darker brown color than the rest of the cyst wall. They were similar to lymphatic glands in appearance. The scar like formations (D, Figs. 9 and 10) referred to had a punched-out border, and the base was composed of lines radiating to the center. The ulcer resembled the scar of a healed ulcer of the stomach. There were three of these scar formations; two about 5 cm. in diameter and one about 10 cm. Distributed irregularly over the cyst wall in varying thickness, from a mere line to several mm. in thickness, were the cord-like, linear elevations referred to in the physical examination (E, Figs. 9 and 10).

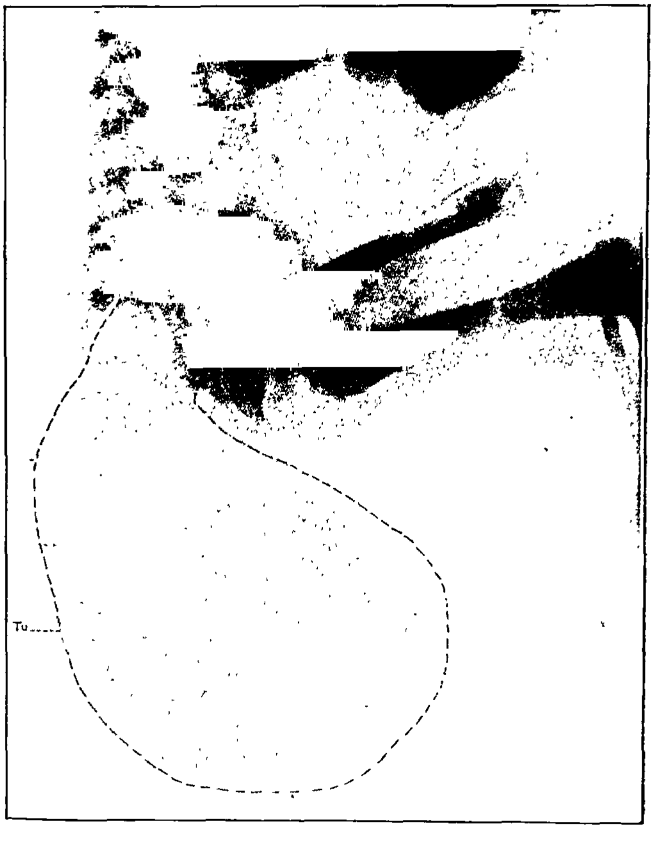

Fig. 6.—Lateral view of tumor (area inclosed by broken line) by *x*-ray.

Sections for microscopic study were taken from three points of interest (Fig. 9): Section I, to show portion of wall of cyst and skin covering it, white fibrous band, and portion of depressed ulcer-like area; Section II, a section of nodule; Section III, through annular thickening described above several blocks were cut in succession at this point and illustrations here will be referred to as III A, III B, and III C.

Section I (Fig. 11, Hematoxylin-eosin Stain).—There is a line of cleavage separating the skin from the cyst wall proper. The stratum corneum of the epidermis is thin; the stratum germinativum thick; the tela subcutanea is lacking in sudoriferous glands and panniculus adiposus, which are replaced by a fibrous connective tissue containing many young blood-vessels. The cyst wall proper (b) is composed of con-

is paper I reported some typical cases of the two l forms of angiomata which are, as a rule, inoperable and, therefore, incurable by the knife. These venous angioma (cavernous nevus), the most t, and the arterial angioma (cirsoid aneurism), is less frequently observed.

e reporting these cases I have had a larger and atisfactory experience in the management of these s, and, in view of the results obtained, must emphahe importance of the method.

ice the injection of boiling water directly into the ance of a tumor composed largely of dilated and is blood vessels causes immediate coagulation, the it of the surgeon is the possibility of embole great dangers which would ensue from this . Of course, in dealing with arterial angioma, no such danger is present, for the reason that the capillaries stand between the coagulating blood and the heart and lungs.

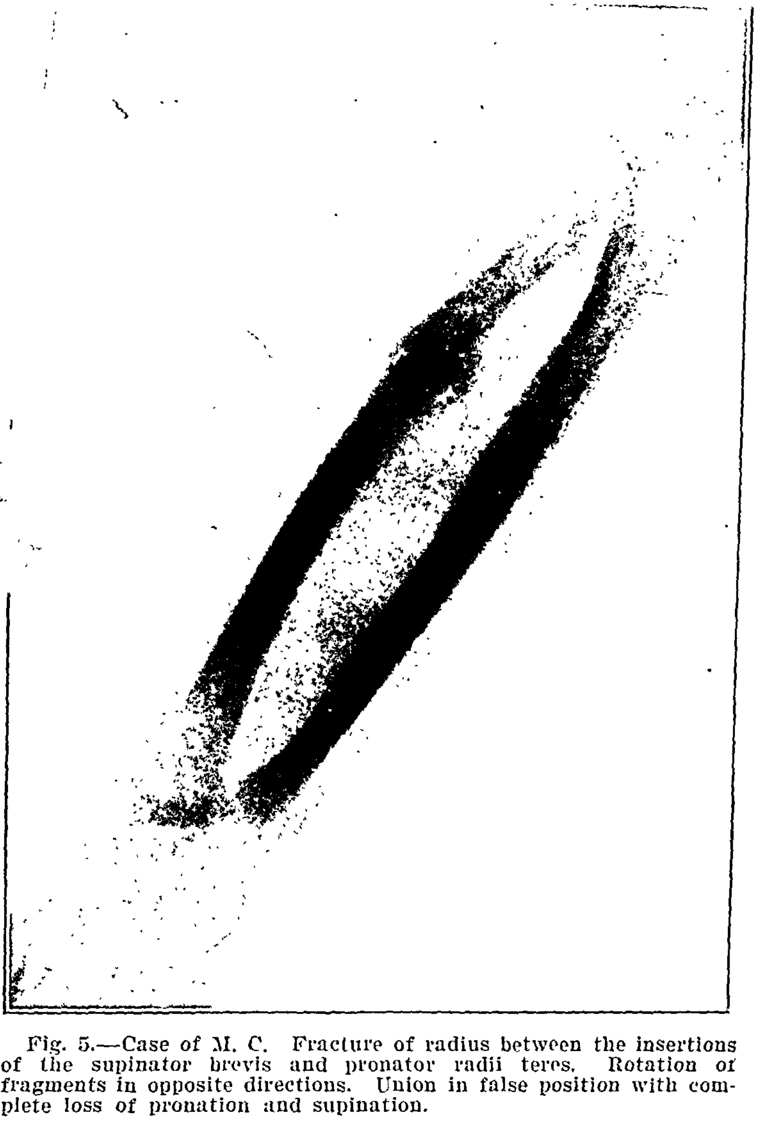

Fig. 5.—Case of M. C. Fracture of radius between the insertions of the supinator brevis and pronator radii teres. Rotation of fragments in opposite directions. Union in false position with complete loss of pronation and supination.

In venous angioma, however, the way is open, and, while I have not yet met with a single case of embolism, every precaution should be taken to prevent this accident.

Most of the neoplasms of this group which I have treated have been located in the neck, generally near the level of the lower jaw, and are in immediate relation to the external and internal jugular veins, as well as the carotid arteries and the large and important nerves of this region.

In the case which I now report, the danger of embolism was so great that I hesitated undertaking the operation, and only did it because the patient's condition was otherwise hopeless.

History.—The patient, F. D., a youth of 19 years, laborer, who, with the exception of the lesion to be described, was in perfect physical condition, came under my observation at the New York Polyclinic Hospital in 1907.

Examination.—Situated on the side of the neck in the line of the internal and external jugular veins, below the angle of the left jaw, was a vascular tumor which measured about three inches in two directions, and projected well beyond the level of the jaw, the tumor having a thickness of between two and three inches. It was of bluish color, and without pulsation. By steady compression, it could be practically emptied of blood and reduced almost to the natural level of the neck. When the pressure was released it filled rapidly and resumed its former size.

On account of the intimate relation of this tumor to the common, *internal* and external carotid arteries, the external and internal jugular veins and the pneumograstric, sympathetic, facial, and spinal accessory nerves, I hesitated to employ the hot water method for fear, first, of causing an embolism in the jugular vein or the internal carotid artery, the first of which would produce death by occlusion of the pulmonary circulation, and second by cerebral embolism and paralysis. A second danger, but one which was less immediate in its effect, was the injury to one or more of the nerves which have been enumerated.

Operation.—Impressed with these dangers, I advised and undertook the removal of this growth by dissection. The hemorrhage, however, was so alarming and seemingly uncontrollable that I was obliged to desist, and had considerable difficulty in arresting it by compression. Three weeks later the following operation was carried out successfully:

To prevent the possibility of pulmonic embolism, the internal jugular was exposed and temporarily occluded by passing around it a large-sized catgut ligature which was twisted and held firmly by an artery clamp. A similar ligature was then thrown around the common carotid artery, and this vessel was in like manner temporarily occluded. The object of this last ligature was to reverse the current of blood in the internal carotid. Blood, like all moving substances, must travel in the direction of least resistance, and in order to prevent the possibility of cerebral embolism, I relied on the force of the unimpeded current to the brain through the internal carotid of the opposite side, and the free anastomosis through the circle of Willis, to carry the blood into the artery of the left side, the stream traveling temporarily downward in its distribution through the branches of the external carotid.

The metal syringe was then filled with boiling water, the piston inserted, and under the barrel of this was held an alcohol lamp in order to keep the water at the boiling temperature. Taking the usual precautions to prevent scalding, by holding a gauze pad in front of the needle as it approached the tumor (for the escape of steam and water from the needle cannot be prevented), the needle was thrust through the gauze as it touched the tumor, and carried well toward the further side of the mass. From ten to fifteen minims were then injected and withdrawing the needle half an inch, this was repeated, until the entire tumor was rapidly subjected to the contact of the hot water.

The result was an immediate coagulation or solidification of the mass. I waited fifteen minutes to satisfy myself of the absence of coagulum in the internal jugular, which could readily have been recognized by the sense of touch. I then removed this ligature. The catgut around the common carotid was then removed.

Result.—There was no suggestion of paralysis and no change in the pupils during or after the operation. The patient made an uninterrupted recovery, has been kept under observation, and now after three years is entirely well. There is no suggestion of a tumor or swelling in the neck, the two sides being symmetrical and normal.

VII. DEMONSTRATION BY EXPERIMENTAL STUDIES ON ANIMALS AND OPERATIONS ON HUMAN BEINGS, OF THE PROCESS OF PERMANENT ARTERIAL OCCLUSION AFTER DELIGATION[3]

April 26, 1882, I presented to the New York Pathological Society a series of specimens which showed the results obtained by the use of broad animal ligatures applied to arteries in continuity. One of these specimens was the carotid artery of a woman which I tied in September, 1881, using the sciatic nerve of a calf which had been made aseptic by treatment in carbolic acid solution. This ligature was not quite one-fourth of an inch in width. The artery was tied just tightly enough to entirely arrest the circulation without doing violence to the inner elastic layer. The patient died seven months after the operation from an intercurrent disease. The artery was completely occluded and its continuity unbroken. There was a slight depression, one-fourth of an inch in width, which marked the exact location of the ligature, every other trace of which had disappeared.

I presented at the same meeting the carotid and subclavian arteries of another patient which I had tied with a broad ligature made of ox aorta after the method of Mr. Richard Barwell of London. This operation had been done for the cure of an aneurism of the ascending segment of the aorta, which operation had proved successful. The patient died one year later from enterocolitis. The occlusion of the arteries was complete, and the condition the same as in the case first reported.

I also presented the carotid artery of a large dog tied experimentally with the nerve ligature. The animal was killed five weeks later, and, as shown, the artery was completely occluded and the continuity of the inner layer seemingly unbroken. In another specimen the carotid artery of a horse was shown. In the application of this ligature, the lumen of the vessel was intentionally not entirely occluded, permitting a portion of the blood current to pass through. Mounted sections of these arteries showed active proliferation in all the normal cells of the arterial wall, most marked in the connective tissue group. They demonstrated that arterial occlusion was the direct result of cell proliferation and the resulting fibrillation and contraction of the new cells of the inflammatory process caused by the traumatism or irritation of the constricting band or ligature.

Scarpa had advanced the idea many years before that it was not necessary to constrict an artery with a ligature forcibly enough to break even the internal elastic layer. Jameson of Baltimore, with this same idea in mind, had later recommended broad animal ligatures made of deer-tendon, but the fact that the clot was an accident of, rather than a factor in, arterial occlusion after the ligature and that closure was due to cell proliferation, *was now for the first time demonstrated.*

When I found in the work of Ballance and Edmunds on "Ligation in Continuity," published in 1891, no mention of these researches, I addressed to them a letter calling their attention to it, and received the following reply:

"LONDON, ENGLAND, Sept. 24, 1894.

Dear Sir:—We are much obliged to you for your kind letter with respect to our book. Its main conclusion is identical with that at which you had arrived long before. We congratulate you on the result of your ligations. Yours very truly,

CHARLES A. BALLANCE,
WALTER EDMUNDS."

VIII. LIGATION OF THE EXTERNAL CAROTID ARTERY

Ligation of the external carotid artery for any lesion in the distribution of this vessel is comparatively a modern operation. Prior to 1878, when the investigations which were given in my "Essays on the Arteries"[4] were made public, in the entire history of surgery the external carotid artery alone had been tied only sixty-nine times. Practically all of these operations were done in ignorance of, or without regard to, the accepted rules laid down in the text-books, for there was then not a work on surgery in the English or any other language, to my knowledge, which did not advise the ligation of the common carotid, rather than the external branch, for a lesion in the distribution of the external carotid alone.

It was said in justification of this position that the branches of the external carotid artery were so irregular in their origin, and at times so close together, that there was not space enough to permit the application of a ligature to the trunk of this vessel.

It had occurred to me as early as 1874 that, as this was the only artery in the human body which was given as an exception to the general law of development, there might possibly be some error in the deductions given in the text-books on surgery and anatomy.

In my investigations I made 121 dissections of the neck with special regard to the terminal divisions of the common carotid. The origin of each of the six regular branches of the external carotid, the distance from the center of bifurcation of the common trunk, and their relations to each other were carefully measured and noted, with the result that it was demonstrated that the external carotid did not differ from the other arteries in the arrangement and relation of its branches, and that it could be ligated in any part of its course as safely as any other artery in the body.

In these essays I collected the histories of 789 cases in which the common carotid artery had been ligated for all causes, with a death-rate of 41 per cent., while in the 69 cases in which the external carotid alone had been ligated—in disregard to the text-books—the death-rate was only 4.3 per cent., a difference in the mortality ratio as based on the results of surgical methods at that time of 36.7 per cent.

When these essays were made public by the American Medical Association, the conclusions reached were universally accepted,[5] and there is to-day not a work on surgery which does not advise the deligation of the external instead of the common carotid artery in all cases for a lesion within the distribution of the former.

The external carotid artery has now been tied in thousands of instances, and the death-rate under the improved technic is practically *nil.*[6] The following is quoted from the report for 1878 of the Committee on Prize Essays of the American Medical Association:

> One paper, in the judgment of your committee, is fully up to the requirements, and should be considered as *two* rather than *one* essay. The analysis of 789 cases of operation on the (common) carotid artery and the careful and minute measurements of the (external) carotid artery and its branches in 121 subjects, showing the range of variation and the percentage of the same, followed by inferences, bold and original, naturally constitutes *a paper complete in itself. Another essay on the same*

---

[3] Published in the Tr. New York Path. Soc., 1882, Med. Rec., July 22, 1882; and in Wyeth: Text-Book on Surgery, 1887, p. 171.

[4] Prizes of the American Medical Association, awarded in 1878; The Surgical Anatomy and Surgery of the Common, External, and Internal Carotid Arteries, and The Surgical Anatomy and Surgery of the Innominate and Subclavian Arteries, William Wood and Co., New York, 1879.

[5] For the immediate acceptance and establishment of these conclusions I was greatly indebted to the late Prof. Henry B. Sands, one of the foremost American surgeons.

[6] I have tied this vessel in several hundred instances without a death, and in three cases the ligature rested exactly in the crotch *of bifurcation of the common trunk.*

> plan with reference to the innominate and subclavian being an analysis of 300 cases, and the observation of 52 subjects, is presented to us in such a maner that we may consider the whole as one prize, or they may compete for both. Your committee believe that both prizes should be awarded to the two essays by one person.

In the American edition of Bryant's Manual for the Practice of Surgery,[7] from the section devoted to this subject, the following is quoted:

> In this connection the views of Dr. John A. Wyeth of New York deserve great attention, for, in his prize essays, presented to the American Medical Association in 1878, he has investigated the subject of ligation of the primitive carotid artery and its branches with such painstaking accuracy that his paper will deservedly become classical. He has collected and analyzed 789 cases of ligation of the common carotid artery, 91 instances of ligation of the external, and 18 of ligation of the internal carotid. In addition, he has given accurate measurements of the arteries in 121 subjects, showing the range of variation and the position of branches. His inferences from this astonishing amount of research are at variance in some respects with the surgical teaching and practice of the day, but it would seem that the profession must be in the wrong, rather than he, who has considered the subject in such a thorough and scientific manner.

IX. BLOODLESS AMPUTATION AT SHOULDER AND HIP

In 1889 I devised the bloodless operation for amputation at the shoulder-joint by elastic constriction over the scapula and pectoral regions, completely controlling the blood supply to the upper extremity. At this operation the applicability of the same idea to hip-joint disarticulation occurred to me, and within a year I did my first bloodless amputation at the hip joint. Both operations were first performed in the surgical amphitheater of the New York Polyclinic Medical School and Hospital.

When the conditions render it permissible, the arm may be emptied of blood by applying Esmarch's elastic bandage. If, on account of the lesion present, this is not advisable, elevation of the member will in large measure allow the blood to gravitate into the body. Two good-sized mattress needles, or preferably the pins specially devised by me, are employed as follows:

The anterior one is inserted through from two to three inches of skin, pectoral muscle and fascia, far enough within the scapulo-humeral articulation to permit free approach to the joint. This pin is anterior to, and does not endanger the vessels. The other is inserted posteriorly over the scapula at the same relative position, and both points are at once shielded with cork. A piece of elastic rubber tubing about half an inch in diameter is wound tightly around the shoulder on the proximal side of the pins. The cumulative pressure of the tourniquet traveling three or four times over the same surface completely closes the blood vessels.

Disarticulation can be accomplished by any of several methods. My own preference, when conditions permit, is a longitudinal incision from the acromion process down to the joint, splitting the deltoid fibers for a sufficient length. From its lower end, a circular or oval incision is carried around the arm, completely dividing the vessels and other soft tissues. The cuff is raised from the bone and the disarticulation effected. The blood vessels are secured, and,as a precautionary measure before closing the wound, the tourniquet may be momentarily relaxed in order to demonstrate any bleeding points which may have been overlooked. This operation has been done in a number of instances, and the hemostasis has been complete in every case.

The bloodless method of disarticulation of the hip-joint was first done by me in February, 1890, and made public before the Nashville meeting of the American Medical Association in that year. The technic is as follows:

The patient is placed with the sacrum resting on the corner of the operating table. The extremity is emptied of blood by elevation of the foot, and, when permissible, by the application of the Esmarch bandage. Two large steel needles about 3/16 of an inch in diameter and ten inches long, are employed. One of these is introduced 1/4 of an inch below the anterior superior spine of the ilium and slightly to the inner side of this prominence, and is made to traverse superficially for about three inches the muscles and fascia on the outer side of the hip. The direction is at right angles to the plane of the body. The point of the second needle is thrust through the skin and tendon of origin of the adductor longus muscle half an inch below the crotch, the point emerging an inch below the tuber ischii. The points should be shielded at once with heavy cork to prevent injury to the hands. No vessels or nerves are endangered by these skewers. A mat or compress of sterile gauze about two inches thick and four inches square is laid over the femoral artery and vein as they cross the brim of the pelvis. Over this a piece of strong rubber tubing 1/2 an inch in diameter when unstretched, and long enough when in position to go five or six times around the hip, is now wound very tightly around and above the fixation needles and secured with a strip of ordinary bandage. If the Esmarch bandage has been employed, it is now removed. The extremity is bloodless, and will remain so.

In the formation of the flaps the surgeon must be guided by the condition of the parts within the field of operation. When permissible, the following method is preferred:

A longitudinal incision commencing at the tourniquet is carried over the trochanter major a sufficient distance down the thigh to form a suitable flap. This is joined at the lower end by a circular incision. A cuff that includes everything down to the muscle is dissected up to the level of the trochanter minor. At about this level the remaining soft parts, together with the vessels, are divided squarely down to the bone by a circular cut. At this stage of the operation, the divided proximal ends of the great femoral vessels are in plain view and should be tied with good-sized catgut. This done, disarticulation is rapidly completed by dividing the muscular insertions from the trochanter and digital fossa, keeping very close to the bone and holding the soft parts away with retractors. The capsular ligament is now exposed and divided, and by forcible elevation, adduction and rotation of the femur, the joint is opened, the ligamentum teres ruptured and the head of the bone dislocated. The remaining vessels, including the saphenous vein, should now be secured—the sciatic artery alongside the nerve, the obturator between the stumps of the adductor brevis and magnus, two or three good-sized branches of the external circumflex beneath the rectus and in the substance of the crureus and vastus externus. The descending branches of the internal circumflex are insignificant, and are usually found on the level of the femoral vessels in the substance of the adductor longus and between it and the adductor brevis and pectineus.

In tying the larger femoral vessels I make it a rule to dissect both the superficial and deep femoral stumps back from one-half to three-fourths of an inch in order to apply the ligature behind any branches which may have been divided close to their points of origin, and I do not hesitate to include the large veins in the same ligature in order to save time. Before closing the stump, it is a wise precaution to loosen the tourniquet in order to see that no bleeding point has been overlooked. The considerable oozing which otherwise would occur from so large a surface may be controlled by introducing a gauze pack into the cotyloid cavity, the end of which is brought out between the flaps for drainage, and then making firm compression with the bandage which holds the dressing on the stump.

The operation has been generally accepted and practiced now in many hundreds of cases. The death-rate from gunshot wounds during the civil war in America was 93 per cent. and between 40 per cent. and 50 per cent. in civil practice in the years preceding the adoption of the method herewith described. It has now been reduced, under modern conditions of hemostasis and asepsis, to about 8 per cent. in disease and 16 per cent. in traumatic cases.

---

[7] Manual for the Practice of Surgery, by Thomas Bryant, F.R.C.S., Surgeon to and Lecturer at Guy's Hospital; edited by Professor John B. Roberts, Philadelphia, 1881, p. 366.

In the *Annals of Surgery*, September, 1895, Dr. John F. Erdman reports that from January, 1884, to January, 1895 (the aseptic period) there were eighteen hip-joint amputations done in Bellevue, Roosevelt, St. Luke's, Mt. Sinai, Chambers Street, German, and Presbyterian hospitals in New York City, with eight deaths, a mortality of 44.4 per cent. Of the eighteen patients, seven were operated on by the method here described, and all recovered, leaving eight fatal cases in eleven amputations by other methods, a death-rate of 72.7 per cent. I do not claim that such a death-rate as this would follow by any other method of operation, but I do insist that my method of hemostasis is so simple and generally applicable that it removes from the procedure all possible danger of operative hemorrhage.[8]

THE TREATMENT OF SARCOMA BY STREPTOCOCCUS AND PYOGENIC INFECTION

That erysipelas has an inhibitory influence on sarcoma, which is at times curative in its effect, has long been known.

In 1882 there was admitted to Mt. Sinai Hospital, in the service of my colleague, Dr. A. G. Gerster, a young woman, suffering with sarcoma of the leg, for which an amputation was made just above the knee. A recurrence took place, followed by a hip-joint disarticulation. The disease again appeared in the stump, developing rapidly into an extensive cauliflower-like mass which became accidentally infected with erysipelas. This infection ran the usual course of erysipelas, during the progress of which the tumor began to diminish in size and eventually it entirely disappeared. In 1907, more than twenty-five years after this experience when this patient was last heard from, she was entirely well, and still actively engaged in her work as a school teacher.

The experiments of Fehleisen and others by direct infection with the *Streptococcus erysipelatis* have confirmed the result in the case above narrated.

Two years later, in my service at Mt. Sinai Hospital, I had the following experience which has since been repeatedly confirmed, namely, that pyogenic infection was capable of producing the same result.

J. P., aged 28, was admitted May 20, 1884, with the following history: A year previous he had received a blow on the abdomen over the right iliac region, which was followed by induration and the development of a neoplasm. At the time of examination, the tumor was 4 by 6 inches in surface measurement, and about 3½ inches in thickness. On account of the involvement of the abdominal wall, it was found impossible to remove it. A section extending almost entirely through the mass was excised and examined by Dr. William H. Welch and two other competent pathologists. The diagnosis of each was spindle-celled sarcoma. Having noticed in a current medical periodical the report of a case of sarcoma, said to have been cured by the direct injection into the substance of Fowler's solution of arsenic, in view of the hopelessness of the patient's condition, I advised this treatment. I began with injections in two or more portions of the mass of from one to three minims of this solution, gradually increasing the quantity to as much as ten minims. These injections were repeated daily for four or five days, then every other day for about ten days. They became so painful that at the patient's request the treatment was discontinued. The increased pain was occasioned no doubt by a pyogenic infection which had supervened. The tumor became red and swollen, and pitted on pressure. The skin did not have the glazed or "stove-polish" appearance of erysipelas, but rather the look of a severe dermatitis. The infection proved to be pyogenic, and several incisions were necessary to permit the free discharge of pus. The patient suffered very considerably from the high temperatures due to septic absorption, but after a period of about two weeks, the tumor began to diminish in size, and with this there was a general improvement in his condition. Four months later his physician, Dr. A. H. Conson of Gainesville, informed me that the tumor had entirely disappeared. The patient regained his former condition of health and survived, without recurrence, eighteen years, and until a few days before his death from acute pneumonia, was hale and hearty, his weight at that time being 170 pounds.

So far as I am able to learn, this was the first known case of a cure of sarcoma by an infective process other than erysipelas. This experience has since been confirmed in a number of instances, one of the most remarkable and instructive of which is the following:

In 1893, J. P., aged 35, of Augusta, Georgia, consulted me in regard to a large tumor occupying the right hypochondriac region. He was anemic, greatly emaciated, and had the marked cachexia of a malignant growth. On account of ascites, he had been tapped on three occasions, and I removed at one operation five gallons of fluid from the peritoneal cavity. With the collapse of the abdominal wall there was felt a hard, round, slightly movable tumor 4 or 5 inches in diameter. It was exposed by an incision about 6 inches in length. To the touch, the tumor was firm, slightly elastic, and occupied the space between the stomach and liver, having developed from the gastrohepatic omentum. It was of a reddish-brown color, and covered in front with a network of large vessels. On account of its vascularity and the feeble condition of the patient, I did not venture to remove a section for microscopic examination, but from its location and macroscopic appearance I have no doubt that it was a sarcoma. The edges of the abdominal incision were retracted so as to permit about one-third of the anterior surface of the mass to present in the wound, while sterile gauze was inserted to secure adhesions and to prevent any general peritoneal infection. Three days later this packing was removed, and the wound and the exposed surface of the tumor were permitted to become infected. Suppuration was soon established; the dressings were changed daily, and within two weeks' time there was a noticeable diminution in the size of the mass and an improvement in the patient's general condition. This wound was kept open, and allowed to suppurate for about two months, at the end of which time, as well as I could estimate, the neoplasm had diminished about one-half its original size. After the wound healed, the shrinkage continued, and six months after the operation it had disappeared. The patient's general health became better from day to day. Five years later I operated on him for hemorrhoids. A few years after his recovery, he married, and is the father of a number of children, and to-day, after a lapse of seventeen years, is in the enjoyment of excellent health.

244 Lexington Avenue.

---

[8] With the introduction of Esmarch's elastic bandage, it was employed in various ways in the effort to control hemorrhage in hip-joint disarticulation. In the Lancet, 1883, i, 897, *Jourdon-Lloyd* described a method in which "a strip of black India rubber bandage about two yards long is doubled and passed between the thighs, its center lying between the tuber ischii of the side to be operated on and the anus. The ends are drawn tight, one in front, and one behind, to a point above the center of the iliac crest."

Trendelenburg endeavored to improve on this method by adding transfixion with a single needle which was passed in front of the neck of the femur and beneath the great vessels. A rubber cord in figure-of-eight fashion was carried over the ends in front, compressing the anterior, vascular portion of the flap.

Fourneaux-Jourdon's plan was a figure-of-eight rubber spica, using the Esmarch bandage in practically the same manner as Jourdon-Lloyd.

Richard Volkmann endeavored to control hemorrhage by circular constriction without needles. His three cases were reported in the *Deutsche Klinik* of 1868, but in each case a preliminary ligature of the femoral was done. That this method was not accepted is evident in the fact that neither in Billroth and Luecke's *Deutsche Chirurgie*; in the *Handbuch der Chirurgie* by Von Pitha; the works of Linhart, nor in the *Centralblatt fur Chirurgie* or *Klinische Vorträge*, of which Volkmann himself was an editor, is there any mention or description of this procedure. I never read or heard of Volkmann's discarded operation until several years after my method had been made public and had been generally accepted by the profession. Of the method, Professor W. W. Keen, of Jefferson Medical College, in a report dated January, 1892, says: "It was reserved for an American surgeon to devise what is undoubtedly the best method, and in fact, what I think we can now call the only method of hemostasis in amputation at the hip-joint."

TABLE 3.—TEMPERATURE OF MONKEY 12 AFTER BEING BITTEN BY INFECTED LICE

	A. M.		P. M.	
	F.	C.	F.	C.
January 23	.....	....	103.2	39.5
January 24	.....	....	103.6	39.8
January 25	103.4	39.7	103.4	39.7
January 26	103.6	39.8	103.9	39.9
January 27	102.7	39.3	104.3	40.2
January 28	102.6	39.2	103.2	39.5
January 29	102.9	39.4	101.9	38.8
January 30	104.2	40.1	103.0	39.4
January 31	103.3	39.6	104.2	40.1
February 1	103.0	39.4	104.0	40.0
February 2	102.7	39.3	103.6	39.8
February 3	103.7	39.8	103.4	39.7
February 4	103.7	39.8	103.3	39.6
February 5	103.6	39.8	104.0	40.0
February 6	103.4	39.7	103.5	39.7
February 7	102.1	38.9	103.7	39.8
February 8	.....	....	103.7	39.8

A definite course of fever cannot be made out positively. If present, it would appear to lie between January 30 and February 5 or 6, a period of seven or eight days, and the incubation period would be seven or eight days. On February 2, the animal was manifestly ill, in contrast to its former active condition, and this condition continued for four or five days. On February 9, however, it was again active and appeared well. At this time an immunity test was given; the temperature is given in Table 4:

TABLE 4.—TEMPERATURE OF MONKEY 12 AFTER IMMUNITY TEST

	A. M.		P. M.	
	F.	C.	F.	C.
February 9	103.9	39.9	103.9	39.9
February 10	102.5	39.2	103.9	39.9

February 23	102.4	39.1	102.9	39.4
February 24	101.1	38.3	103.2	39.5
February 25	102.9	39.3	102.4	39.1
February 26	102.4	39.1	103.7	39.7
February 27	102.4	39.1	102.6	39.2

Continued similarly for twelve days more.

The controls were Nos. 3, 24 and 25, already cited. A second immunity test resulted in the same way. No. 20 (see above) being the control. During neither of the immunity tests did the animal show any sign of illness.

No. 25 is a particularly good control for No. 12, since, like the latter, its temperature was naturally high and irregular. The course of fever was as shown in Table 5:

TABLE 5.—TEMPERATURE OF MONKEY 25, CONTROL OF NO. 12

Continuing as before the fever appeared.

In our opinion, the result justifies the conclusion that No 12 was infected by the lice of Group 5.

INFECTION OF THE MONKEY BY INTRODUCING INTESTINAL CONTENTS OF LICE INTO SCARIFICATIONS

A first experiment, which consisted of the subcutaneous injection of the intestinal contents of infected lice, resulted in death in less than twenty-four hours, from septicemia.

A second experiment was performed as follows: As the lice of Group 5 were feeding on Monkey 12, a small quantity of feces was collected from a number of the lice as it was extruded, and placed in a sterile test-glass. To this material the abdominal contents of three lice were added and the mass was triturated in sterile salt solution. This was done three days after the last feeding of the lice on the infected Monkey 7.

Twelve small incisions, each less than one-eighth inch in length, and extending through the entire depth of the skin, were made in the abdominal skin on Monkey 13. The emulsion of feces and abdominal contents was then instilled into these incisions, which thereafter were massaged by means of a sterile probe. The incisions healed promptly and without suppuration. The temperature of No. 13 was as shown in Table 6:

TABLE 6.—TEMPERATURE OF MONKEY 13 AFTER INFECTION WITH ABDOMINAL CONTENTS OF INFECTED LICE

	A. M.		P. M.	
	F.	C.	F.	C.
January 26	102.7	39.3	103.4	39.6

January 28	100.3	38.0	102.1	39.0
January 29	102.2	39.0	101.9	38.8
January 30	102.8	39.3	104.0	40.0
January 31	103.3	39.6	103.9	40.0
February 1	103.0	39.4	103.8	39.8
February 2	102.2	39.0	103.8	39.8
February 3	104.4	40.2	102.4	39.1
February 4	103.7	39.8	103.0	39.4
February 5	102.4	39.1	103.1	39.5
February 6	101.8	38.7	102.1	39.0
February 7	102.0	38.8	103.0	39.4

As appears in the table, the temperature rose on the fifth day after inoculation and remained above the normal for this animal for five or six days. During this period the animal became passive and was not inclined to run about, although it was not seriously ill at any time.

As a consequence of an immunity test given on February 9, the animal showed no febrile reaction whatever and appeared perfectly well, whereas the controls (Nos. 3, 24 and 25) reacted with severe fever, as stated above. A second immunity test, given a month later, gave the same results, the control in this instance being No. 20 (see above).

In our judgment, this experiment proves the existence of the virus of typhus fever in the abdominal contents of the louse for at least three days after feeding on infected blood.

SUMMARY AND CONCLUSIONS

1. It seems that *Macacus rhesus* can be infected with tabardillo invariably by the injection of virulent blood from man taken on the eighth to tenth day of fever. The blood should be diluted with salt solution, as stated previously.

2. Attempts to maintain typhus in the monkey by passage through other monkeys were not successful.

3. The monkey may pass through an attack of typhus so mild that it cannot be recognized clinically. Vaccination results.

4. The immunity test is a reliable proof of the previous occurrence or non-occurrence of typhus at least within a period of one month.

5. Typhus was transmitted to the monkey by the bite of the louse in two experiments, the lice in one instance deriving their infection from man and in another from the monkey.

6. Another monkey was infected by typhus through the introduction of the feces and abdominal contents of infected lice into small incisions.

Other experiments, in which the immunity tests have not yet been given, corroborate the carrying power of the louse.

As to whether these experiments on transmission are to be considered merely as substantiating that of Nicolle, or whether they should be regarded as new observations, will depend on the identity or non-identity of tabardillo with the Old World typhus. If *Macacus rhesus* is susceptible to the direct injection of blood from patients suffering from tabardillo, and not to the injection of the blood of the Old-World typhus, the two diseases in our judgment cannot be regarded as identical, although they may be closely related. As stated in a previous paper, Nicolle was unable to infect the macacus directly with human blood, but succeeded first in infecting the chimpanzee and then the macacus by the injection of blood from the chimpanzee. Nicolle's result, if it is to be regarded as final, when compared with ours and with those of Anderson and Goldberger, seem to indicate non-identity of the disease in the two localities.

It would seem that Nicolle's work, at least in this regard, demands repetition. Possibly, also, the point may be elucidated further by determining whether an attack of Old-World typhus confers immunity to tabardillo.

We are greatly indebted to Director Gaviño of the Bacteriologic Institute, to his assistant, Dr. Girard, to their superiors of the Department of Public Instruction, to the authorities of the General Hospital of the City of Mexico in particular to Dr. Escalona, for their numerous courtesies and cooperation.

A PRELIMINARY REPORT OF THE PEDIATRIC DEPARTMENT OF AN OUTDOOR MATERNITY CLINIC

ALSO A PLAN BY WHICH INFANT MORTALITY MAY BE REDUCED IN LARGE CITIES *

HERMAN SCHWARZ, M.D.
Assistant Adjunct Pediatrist to the Mt. Sinai Hospital
ASSISTED BY ADELAIDE BOWLAND, R.N.
NEW YORK

The outdoor maternity service mentioned in the title of this paper is one conducted by Dr. I. L. Hill in New York City for the past nine years. By means of graduates and undergraduates who desire experience in obstetrics, six to seven hundred women are treated during childbirth in their tenement homes in the course of a year. In November, 1908, I organized a pediatric department to this outdoor maternity service, a novelty in this country.

As soon as the mother applies for aid a social worker calls at her home and obtains on a special card exact data concerning the age, nationalities of parents, previous pregnancies, premature deliveries, miscarriages, causes of death of these children, parents' occupation, total earnings of family, rent paid per month, housing conditions, number of people per room, boarders, cleanliness, amount of food, knowledge of infant hygiene, general intelligence, willingness to cooperate, mother's general condition, etc. Should these notes show that the woman required medical care, this is obtained for her. If other conditions are present, she is referred to the various charities, so as to put her in the best possible condition for the child birth.

As soon as the child is born a trained nurse is sent to the house and instructs the mother in the principles of infant hygiene. The child is seen every day until it is taking the breast properly. The nurses are impressed with this, for it is our aim to supply that link in the chain which is missing in other institutions that we know of, namely, to get the care of the child before its birth and from its birth, to be sure that it is nursing well or to find the reason why it is not.

The first day the child is taken into the street it is brought to the clinic, and this clinic visit is repeated once a month until the child is a year old. We realize that this time limit is rather short, but we also know that the first half-year is the most important and needs absolute follow-up work. Every child is seen once a month somewhere, either on the street, in its home, or at the clinic. In order to do this the children are indexed as to names in a book where the months of the year are ruled off in perpendicular parallel columns. Each time a child is seen a mark is made opposite its name. At the end of the month every child must have had its present mark in evidence, or the parents are written to or called on. The only way we lose track of our cases in this great city is by being unable, in spite of all possible detective work, to find out the new address. Thus we have taken care of 784 children; 100 we have lost track of, and 38 have died. The average attendance at the clinic was 14; largest number, 40; attendance during the year, 2,042. During July, August and September, 1,872 house visits were made. The cost of this work, including rent, salaries of three nurses and one social worker, gas, telephone, etc., was $350 per month, or about $4,000 per year. Much interesting data as to infant mortality and sociologic conditions have been gathered during the progress of the work, which will be published elsewhere *in extenso*.

One of the main objects of this work is the propaganda of breast feeding, which, to our minds, is the most important element in the reduction of infant mortality. The changes in the sociologic conditions, which must not be underestimated, are but a means to this end. Statistics of breast feeding, both as to the number of children on the breast and the duration of this manner of feeding, are entirely lacking in America. There are many methods by which this information has been obtained more or less completely—by questioning physicians, midwives, at public vaccinations, in clinics, and in the census taking. The most reliable method is to follow each child individually and, as it becomes a bottle baby, put it in that class. The following is a table which we have been able to compile, showing the number and length of time our babies have been breast babies:

Number of Infants.	Time Observed Months.	Number on the Breast.	Percentage.
641	1	616	96
532	2	486	91.3
472	3	423	89.6
387	4	331	85.5
309	5	250	80.9
258	6	196	75.9
181	7	123	67.9
138	8	95	68.9
92	9	60	65

From this it will be seen that of our babies observed for five months 80 per cent. were on the breast, which is up to the critical period of their lives. One might here sound a warning to all charitable institutions, hospitals and dispensaries, that have to do with the distribution of and by the prevention of intermediary hemorrhages between the layers of the tissues. That, at least, is the only way by which we could explain the fact that, for instance, suprapubic prostatectomies practically healed up inside of three days in men varying in age from 70 to 83 years. Another advantage of this method is that, in accordance with the experience of Klapp and Hoerman, patients under this reduced circulation require smaller quantities of the anesthetic given and recuperate more quickly from the anesthesia.

---

* Abstract of an address before the Section on Hygiene and Public Health of the Academy of Medicine, New York City, Dec. 14, 1909.

The disagreeable sensations produced by rubber constriction are entirely absent in this method, and any appreciable changes in the blood-pressure, as observed in Momburg's compression of the abdominal aorta, are not to be found. We want to recommend emphatically this simple and effective procedure to the attention of the profession. There is no doubt in our mind that this method can be used just as successfully in other surgical operations as in those mentioned above.

92 State Street.

Therapeutics

CREOSOTE IN PULMONARY TUBERCULOSIS

If one were to base an opinion on current medical literature, he must conclude that the use of drugs in the treatment of pulmonary tuberculosis had been practically abandoned, and that nourishing food and fresh air were adequate to cure most cases of the disease. It would be grossly unfair to the physicians of three or four decades ago to assume that the use of these latter remedial agencies was unknown or ignored by them. The value of food and fresh air is no new discovery, but has long been insisted on by sensible and practical physicians, though, of course, the general adoption of the plan of sleeping out-of-doors did not attain great popularity until comparatively recently, and perhaps has already experienced its most extensive practice.

Although the treatment of pulmonary tuberculosis in institutions is now a steadily growing fashion, it does not to-day seem probable that the multiplication of sanatoria will lead, at least in the present generation, to the entire abolition of tuberculosis from civilized communities, nor is it likely that the time will ever come when a very large proportion of tuberculous patients will be treated in sanatoria. On the other hand, it is extremely probable that the majority of these patients will continue to be treated in their own homes.

Consequently it becomes a question of great practical importance to every general practitioner to know whether any drugs can be expected to benefit his patient and assist and increase the improvement derived from food and pure air.

A number of drugs have been highly commended and extensively used with asserted benefit. Perhaps none has been more commended and used than creosote; but, rather curiously, there does not seem to be any general agreement as to its value or uselessness. Many physicians who are looked up to as authorities on the subject, among them heads of sanatoria, teachers and hospital attendants, ignore it entirely, some with a manner as though they had scarcely heard of such use of the drug. Others pass it on with slight mention, or enumerate it in a perfunctory way among the drugs which have been recommended.

On the other hand, not a few men do not hesitate to advise its use, and assert with the assurance of decided conviction that it is exceedingly beneficial in this disease; indeed, more beneficial than any other drug. Among its distinguished advocates is Dr. Beverley Robinson, of New York, who for more than twenty years has been using and praising the drug in tuberculosis of the respiratory organs. He asserts that he practically introduced the treatment in New York and read a paper on the subject before the Association of American Physicians over twenty years ago. Since then he has used the treatment continuously, and recently (*Medical Record*, Nov. 20, 1909) asserts: "I have written and spoken many times on this subject, and tried in every way to convince my colleagues that I was in dead earnest in regard to the doctrine preached. To-day I am thoroughly convinced that we have absolutely no medical treatment of pulmonary tuberculosis at all equal to the creosote treatment properly used and insisted on. In fact, I might say, without much fear of effective contradiction, that no other medical treatment up to date has any great value at all, except so far as temporary relief, perhaps, of symptoms is concerned. . . . By the combined, persistent, intelligent use of beechwood creosote internally and by inhalation, many patients may be saved who otherwise would die. In nearly all cases, no matter what the stage of the disease, much relief to symptoms may be obtained."

Robinson thinks that the best method of administering creosote internally is in the following combination:

℞.	Creosoti (beechwood, the best)	gtt. vi
	Glycerini	fl.℥i
	Spiritus frumenti	fl.℥ii

M. et Sig.: A desertspoonful every two, three or four hours, diluted with a little water.

Or this may be written as follows:

		Gm. or c.c.
℞.	Creosoti (beechwood, the best)	50
	Glycerini	25
	Spiritus frumenti, ad	100

M. et Sig.: A teaspoonful, in water, three times a day, after meals.

The dose of this may be increased to two or three teaspoonfuls, or, if it is desired to increase the creosote, the amount of it may be increased to 1 c.c. or more in the 100 c.c. mixture. If the whiskey is deemed inadvisable, elixir calisaya or the compound tincture of cardamon may be substituted.

For inhalation Robinson (*American Journal of the Medical Sciences*, August, 1908) recommends equal parts of creosote and alcohol, or, when there is much irritative cough, equal parts of beechwood creosote, alcohol and spirit of chloroform. Ten drops should be used on the sponge of a perforated zinc inhaler. The inhaler should be used frequently, at first for a few minutes, later gradually increasing the time until it is used from half an hour to an hour at a time, and finally it may be used almost continuously during the day, and frequently all night. "These inhalations modify sputum favorably, diminish its quantity, lessen cough, thus promoting rest, sleep and nutrition and general improvement physically, and in some instances appear to be the means through which the patient has gotten rid of tubercle bacilli permanently."

Such positive evidence by a man of Dr. Robinson's extensive clinical experience; extending, as regards the use of this particular drug, over twenty years, should carry greater weight than the negative testimony of a writer who has ignored the use of creosote because, perhaps, some favorite teacher has not recommended it.

Somewhat less enthusiastic testimony came to us, not so very long ago, from England. In a public lecture on

"The Evolution of the Treatment of Pulmonary Tuberculosis," delivered in connection with the sixth International Congress on Tuberculosis, at Horticultural Hall, Philadelphia, Sept. 24, 1908, and published in the special volume supplementary to the transactions of the Congress, Dr. C. Theodore Williams, of London, an eminent phthisiographer, says: "Creosote, and its derivative guaiacol, has been largely used in the treatment of consumption, principally by the French and Germans. Their reported successes led me to give both a trial, my chief experience relating to creosote.

"I tried this method largely according to various methods in tuberculous disease of the lungs. First, by inhalation of steam impregnated with creosote vapor. Patients lived and slept in rooms impregnated with this atmosphere.

"Secondly, dry creosote vapor, produced by heating it in an evaporating basin. Patients inhaled this vapor for from one-quarter to half an hour at a time, and this practice was continued for months.

"Thirdly, creosote was administered by the mouth in capsules, in doses of three to ten minims, three times a day, for weeks and months.

"Fourthly, creosote was mixed with olive oil, as recommended by Dr. Gimbert, of Cannes, in the proportion of 20 minims to half an ounce of olive oil, and injected subcutaneously. As much as a tablespoonful was injected at a time, and shortly afterward the patient used to taste the creosote in the mouth.

"The results of these experiments taught me that creosote has a wonderful influence in reducing catarrh and diminishing the amount of expectoration, but that it exercises no control over the evolution or spread of tubercles."

It has seemed worth while to present these remarks in full, not only on account of the position which Dr. Williams occupies as a trustworthy contributor to the literature of the subject of tuberculosis, but also because the entire lecture is printed in a volume of the very voluminous transactions of the congress, where, it is greatly to be feared, it will be overlooked by many who ought to read it.

In the present unsatisfactory and uncertain state of the treatment of pulmonary tuberculosis, the testimony of such distinguished clinicians that creosote affords considerable relief to many patients would seem to indicate, to put the matter most conservatively, that every practitioner who is treating a patient who has pulmonary tuberculosis should at least consider seriously the desirability of giving that patient the opportunity of obtaining any benefit, which in his particular case may be possible, from the use of creosote.

Now, just what is creosote expected to do to these tuberculous patients? The appetite should be increased, digestion stimulated, nutrition improved, weight added, expectoration diminished, the pus in the sputum lessened, the disagreeable odor from the sputum should disappear, and associated non-tuberculous laryngitis, tracheitis and bronchitis of the larger tubes should be cured. It can do all this when associated with fresh, clean air, good food, and rest.

What has driven creosote to the defensive is that so many results are no better than those from fresh, clean air, good food, and rest without creosote, and that so much harm has been done with creosote. The large doses advised and used so long are really inexcusable. Pushing creosote to the point of tolerance and then reducing it and again pushing it to the point of tolerance, until 10, 15, 20, 25, or even 30 drops, three times a day are taken and retained, is unjustifiable. The demand of the body from this nutrition stimulant for the organs to work overtime is bound to result, sooner or later, in a great loss to the body by the overworked organs going on strike. And this is just what occurs after too much creosote has been taken. The appetite is lost, the tongue becomes coated, nausea and vomiting occur, the liver acts sluggishly, there is a yellow tinge to the sclerotics, the pancreatic secretion is lessened, sugar or albumin may appear in the urine, serious kidney irritation and bladder irritation may develop, headaches occur, there is a loss of red corpuscles, there is a loss of weight, and the patient is where he began, as to nutrition, before he took the creosote.

Small doses of creosote may inhibit the growth of or kill the tubercle bacilli that are swallowed into the stomach (so will dilute hydrochloric acid in small doses) and will often increase the appetite and digestion, especially the pancreatic. It acts as a bowel antiseptic, and in small doses will not ordinarily injure the kidneys. Part of the creosote will be excreted by the lungs, and will inhibit the growth of secondary germs of infection (pus germs), and in so much certainty acts for good in pulmonary tuberculosis. The dose, however, that acts for good must be individualized, and is not large. The tongue and digestion should be watched, and the urine frequently examined for albumin during the administration of creosote, and any symptoms of overaction should cause it to be stopped.

Creosote is a phenol poison, and the symptoms of its poisonous action are those of phenol (carbolic acid): gastro-intestinal disturbance, circulatory depression, nervous depression, and kidney inflammation.

It seems probable, from all the testimony presented, that there are patients suffering from pulmonary tuberculosis who will do better on fresh clean air, good food, rest, and creosote than without the creosote. Whether creosote will be of advantage to a given patient must be determined by studying him while he is taking it. It is theoretically indicated if he expectorates a lot of yellow, bad smelling pus; in other words, has a secondary bronchitis or cavities. Albumin in the urine or persistent dyspepsia would contraindicate its use. It should not be forgotten that creosote is more or less absorbed when inhaled, and can thus irritate the kidneys.

Besides the combination for inhalation suggested by Robinson, the following formulas may be used:

℞,	c.c.		
Creosoti (beechwood, best)	1	or	m. xv.
Tincturæ benzoini comp.	100		fl.℥iii

M. et Sig.: To inhale a teaspoonful, from boiling water, three or four times a day.
Shake.

Or:

℞,	c.c.		
Creosoti (beechwood, best)	50		m. vii
Olei pini silvestris	10	or	fl.ʒiiss
Tincturæ benzoini comp., ad	100		ad, fl.℥iii

M. et Sig.: To inhale a teaspoonful, from boiling water, three or four times a day.
Shake.

Or:

℞,	c.c.		
Creosoti (beechwood, best)	50		m. x
Olei pini silvestris	5	or	
Olei terebinthinæ	5		āā, fl.ʒiss
Tincturæ benzoini comp., ad	100		ad, fl.℥iv

M. et Sig.: To inhale a teaspoonful, from boiling water, three or four times a day.
Shake.

THE INTRAVENOUS INJECTION OF ANTITOXIC SERUM

By serum therapy we aim to introduce into the body, in the most effective manner, specific antibodies and to maintain a high concentration so long as necessary.

The results of investigations as to the influence of the place of introduction on the time when the maximum concentration of antibodies in the blood in passive immunization is reached may be summarized to this effect: On intravenous injection the maximum concentration is reached at once, while on subcutaneous, intramuscular and intraperitoneal injection it is reached only after an interval variously stated at from twenty-four to forty-eight or seventy-two hours. In man, Henderson Smith[1] found absorption of diphtheria antitoxin from the subcutaneous tissue complete only after two or three days. In the case of certain agglutinins and of diphtheria antitoxin, the maximum concentration (according to Levin[2]) in the blood in animals is reached in about three days after subcutaneous and intramuscular injections, but during the first twenty-four hours the absorption is greater from the muscles than from the subcutaneous tissues—at the end of ten hours it is fourteen times greater.

Levin also found that the introduction in animals of immune serum, no matter whether from the same or different species and whether by intravenous, intramuscular or subcutaneous injection, appears to be followed by an immediate and marked loss in antibodies for which he could offer no explanation. That is to say, the demonstrable content of antibody in the serum of the animal in all cases falls far short of the amount calculated on the basis that the antibodies are simply diluted in the blood. This deficit in his experiments was greatest when the antiserum was introduced subcutaneously, less when introduced intramuscularly and least when introduced intravenously, but even here it amounted to from 40 to 60 per cent. and in some cases more.

The fact that intravenous injection immediately gives a far greater concentration of antitoxin and other antibodies in the blood, and hence in the lymph also, thus reaching all parts, than is ever attained by the gradual absorption from the subcutaneous tissue is a strong point in favor of the direct injection into the blood of antidiphtheritic serum in severe and urgent cases. This is urged by Behring, Madsen and others. The principle is, of course, equally applicable to other conditions. According to Berghaus,[3] the curative value of antidiphtheritic serum for guinea-pigs on direct injection into the blood is 500 times greater than on subcutaneous injection and from 60 to 90 times greater than on intraperitoneal injection. Schreiber[4] and Berlin[5] injected antidiphtheritic serum intravenously in a number of cases. They state that general improvement follows sooner than on subcutaneous injection, while the local process in the throat follows about the same course in both cases. And that in very severe cases and in cases coming under treatment late in the disease the intravenous injection of large doses may offer the only chance. In their series no dangerous symptoms developed. Fette[6] injected 145 patients intravenously and believes that the lives of several desperately ill patients were saved by so doing. According to Park,[7] large doses of antitetanic serum injected intravenously within a few hours of the onset of the symptoms of tetanus have given good results.

In case of difficulty in entering the vein in suitable cases, it is advised that the injections be made into the muscle of the buttock which, so far as concerns the rapidity and degree of absorption of antoxin into the blood, is a more favorable place for injection than the subcutaneous tissue.

The one objection of any consequence against the intravenous method is the increased danger of anaphylactic shock in susceptible persons. But in order still further to reduce the mortality from diphtheria this risk may well be taken in desperate cases. Says Ker:[8] "Occasionally I have seen an intravenous injection act almost like magic in an entirely hopeless case."

THE REVISION OF THE NATIONAL FORMULARY

The national Food and Drugs Act raised the National Formulary to the position of an official standard and gave it a significance and an importance which previously it could not claim. In order to meet the requirements of the new function of this book, the American Pharmaceutical Association, at its last meeting, invited the Section on Pharmacology and Therapeutics of the American Medical Association to cooperate in the revision and a committee of five members was appointed.

This idea of having the cooperation of physicians is a good one, for the National Formulary is a book in which physicians are becoming more and more interested since the propaganda against nostrums was initiated. A thorough study of the book is now necessary in order to adapt it more closely to our present knowledge and to eliminate certain features that are not a credit to it. When some of the formulas were selected there was not sufficient investigation made to show whether or not they were of therapeutic value; and in others there was evident disregard of chemical and other incompatibility. Thus, in liquor antisepticus alkalinus, small amounts of reputed antiseptic drugs satisfied the implied demand for an antiseptic solution, and no investigation was made to determine whether or not the strength was sufficient for antiseptic or germicidal results. In a similar manner, because acids were found to be necessary to the digestive action of pepsin, a little acid (not sufficient for any therapeutic purpose) was added to a popular digestive powder. The same thing was done with the compound elixirs; and thus was perpetrated the absurdity of combining pepsin and pancreatin in an acid solution, an incompatibility that we fully demonstrated three years ago.[1] But it is asserted that the use of elixir digestivum compositum (N. F.) and proprietary elixirs of similar composition as a vehicle in the administration of salicylates, bismuth salts, bromids, etc., is actually on the increase. It hardly seems possible that this can be true, that a physician should continue to use something supposed to be a digestive when all he needs is a suitable elixir. But there is no doubt that the demand for these elixirs and for the proprietaries of which the elixir digestivum compositum is an imitation is to a great extent a demand for a vehicle. The Pharmacopeia already contains two highly alcoholic elixirs which serve as vehicles, elixir adjuvans and elixir aromaticum, so that it would seem unnecessary to add still another more or less similar preparation. If, however, it is deemed desirable to have a colored vehicle, one could be made by omitting the digestives from the elixir digestivum compositum and giving it a name to signify its use as a vehicle.

[1] Jour. Hyg., 1907, vii, 205.
[2] Ztschr. f. Immunitätsf. u. exp. Therapie, 1909, i, 3.
[3] Centralbl. f. Bakt., I, 1909, l, 87; Also experiments of F. Meyer, Berl. klin. Wchnschr., 1909, xlvi, 1202.
[4] München. med. Wchnschr., 1909, xxxv, 1597.
[5] Deutsch. med. Wchnschr., 1910, xxxvi, 210.
[6] Med. Klin., 1909, v, 1891.
[7] THE JOURNAL, Jan. 22, 1910, p. 254.
[8] Infectious Diseases, 1909.

The medical men who have been selected to advise the committee on revision on the question of the character of the formulas to be included in the book are supposed to be chosen for their knowledge, not of pharmacy, but of therapeutic possibilities. It is evident, therefore, that therapeutics is to be guarded as well as pharmacy in this revision.

It has been suggested that all complex formulas and mixtures should be left out of the Pharmacopeia. The suggestion may be a good one. All such formulas found pharmaceutically correct and therapeutically efficient might then be included in the National Formulary. There should be added also the formula of a simple vehicle as suggested above; and there might be included formulas for mouth-washes or throat-washes, external applications such as liniments, pastes, ointments and counter-irritants, and perhaps injections of various sorts. These could be given by way of suggestion as to strengths that might be employed and as to pharmaceutical elegance and suitability rather than as set formulas to be used for all patients without variation. The book, however, should not mislead any physician by containing preparations that are worthless therapeutically or chemically impossible. It should be kept in mind that the use of set formulas in prescribing is not scientific, and the aim should always be to prescribe single drugs or simple combinations directly adapted to the case in hand. Until that method is followed by physicians universally, however, some of the present formulas now included in the Formulary will perhaps have to be retained.

CARCINOMA OF THE TONGUE

Much of the recent discussion concerning the increase of cancer is confined to statistics relative to cancer of the uterus, breast and stomach. It is pertinent, therefore, to call attention to a form of carcinoma of the epithelioid type (epithelioma) which is quite as fatal as any other.

Of the epithelioid type, carcinoma of the tongue is much more frequent than is commonly supposed. Andrew of Glasgow presents some very surprising statistics relative to epithelioma of the tongue. Of 118 cases comprising various diseases of this organ, such as abscess, hematoma, glossitis, leucoplakia, papilloma, and tuberculous ulcer, 98 were cancer of the epithelioid variety. Of the 98 patients, 88 were males and 10 were females. These figures are similar to those obtained for cancer of the lip. Andrew found that in 469 cases of epithelioma the order of frequency was: tongue, lower lip, esophagus, penis, cheek, larynx and tonsil. In other words, epithelioma of the tongue comprised 20.8 per cent. of all cases of epithelioma seen during a period of ten years. Of the 118 cases there was only one case of tongue syphilis, or 0.8 per cent. The tongue and floor of the mouth are very rich in blood vessels and this, combined with the constant muscular movements of the tongue, produces a quick extension of the cancerous process into the lymphatic and submental and submaxillary glands.

The entire statistics cited by Andrew cover the histories of over forty thousand cases of general diseases, and bear out the opinions of the rhinologists and stomatologists who naturally see cases of tongue disease more frequently than the average general practitioner.

It needs to be emphasized that tertiary syphilis is rare in the tongue—a fact which is by no means well known. Recently three cases were reported in which several physicians diagnosed gumma of the tongue, and the patients were given iodids in large doses. Each of these cases, when a section of the tongue was taken, proved to be epithelioma, and all were practically inoperable at the time the true diagnosis was made.

However, if the patient has had an initial syphilitic lesion it is necessary to be on guard, for Brandt of Berlin says that it is not uncommon to find carcinoma arising from the base of a syphilitic ulcer and Koerner of London has seen at least twelve undoubted cases in the tongue. These observations are somewhat discounted by the statement previously made relative to the infrequency of syphilitic tongue conditions, but the possibility should be kept in mind.

---

[1] Liquid Combinations Containing Pepsin and Pancreatin, THE JOURNAL A. M. A., Feb. 2, 1907, xlviii, 434

A leukoplakia, a fissure or an ulcer of the tongue should not be temporized with, but a portion of the growth should be submitted early to microscopic examination. It need scarcely be stated that the cure of cancer anywhere in the body depends on early diagnosis and complete eradication. Anything short of this means that the patient is deprived of the only opportunity he has of preventing a speedy and fatal termination of his malady. It is well, therefore, to be constantly on guard as to all suspicious lesions of the tongue.

RECENT ACTIVITY FOR A SAFE CELEBRATION OF THE FOURTH OF JULY

Never before has there been so much fruitful effort toward the securing of a safe celebration of the Fourth of July as during the past few months. Action thus early in the year is well advised for two chief reasons: First, before dealers in fireworks have laid in their supplies, valid objections cannot be raised to prohibitive or restrictive ordinances, and such ordinances are more easily secured; second, ample time is needed to plan other forms of celebration. Hundreds of cities and towns throughout the country have passed or are being strongly urged to adopt restrictive or prohibitory ordinances against the use of fireworks. Various organizations are taking an active part in the work. One city council, that of Hamilton, Ohio, recently passed an ordinance prohibiting the sale of fireworks, which was objected to by dealers on the ground that having already laid in their stocks of fireworks the enforcement of the ordinance would result in serious financial loss to them; whereupon the people raised a fund, bought up all the fireworks and will hold an exhibition in the public park on July Fourth. Meanwhile the ordinance will be made effective. Equally interesting is the movement to substitute other forms of celebration, and many cities report plans for pageants, military parades, flag-drills, picnics, etc. One city has raised a fund of $60,000 for this year's celebration. That the larger cities are undertaking these safer and more sensible methods of celebration is especially encouraging, since it will be a stimulus to smaller cities to do likewise.

ANOTHER FRAUDULENT PRACTITIONER ELIMINATED

According to the *Texas State Journal of Medicine* "the greatest charlatan and quack that ever imposed on the credulity and gullibility of the Texas public" was put out of business in Judge Camp's court at San Antonio, March 4, when a jury brought in a verdict revoking the license of "Doctor" Lafayette Berry, the self-styled "Phenomenal." He had worked in many cities in Texas and had relieved many people of money by flagrant and fraudulent methods. He made a practice of touring the state with a company of performers and a brass band doing what he styled "bloodless surgery" on opera house stages and in public halls. Having been exonerated of fraudulent practices by minor courts several times, he became arrogant and bold in his denunciation of the medical profession. One of his strongholds was his apparent success with gall-stones. It is said that he used olive oil, followed by an alkali, and the resulting concretions of soap passed by the patient were claimed by him to be gall-stones. Our Texas exchange states that he secured $25 from Captain Moore, of the Beaumont fire department, by this plan. The matter was taken up by the profession of the city, the fraud exposed, the "Phenomenal" was brought into court and his license revoked as stated. On examination in court the "doctor" admitted that he had never graduated in medicine, but had secured a diploma from an Eclectic school in Philadelphia after two months' attendance and had obtained another from a school in San Francisco without any attendance. The profession of Texas and the *Texas State Journal of Medicine* deserve credit for their persistent and successful efforts to rid the state of this notorious quack.

Medical News

ARIZONA

Hospital Burned.—St. Mary's Hospital, Douglas, was burned February 10, with a loss of about $5,000. The patients were removed without casualty.

Society Meeting.—At the annual meeting of the Pima County Medical Society, *held in* Tucson, Dr. Ira E. Huffman was elected president; Dr. Abram Morrison, vice-president, and Dr. A. Garfield Schnabel, secretary-treasurer, all of Tucson.

Convicted of Violating Health Law.—A jury in Phoenix is said to have found Dr. Benjamin B. Moeur, *Tempe, guilty of* a misdemeanor in failing to report to the Maricopa county board of health, a case of smallpox in that city, and a fine of $20 was imposed. Dr. Henry A. Hughes, superintendent of the count yboard of health, was the *complaining witness in the* case. The defendant's attorney gave notice of his intention to appeal to the district court.

ARKANSAS

Fortune for Sanitarium.—By the will of A. W. Shirey, Mintern, who was assassinated March 8, $200,000 is left to the Grand Lodge of Odd Fellows to establish a sanitarium at Hot Springs.

District Society Meeting.—The semi-annual meeting of the Tenth Councilor District Medical Society was held in Fort Smith, March 15. Dr. Thomas Douglas, *Ozark*, was elected president; Dr. James J. Smith, Paris, vice-president; Dr. Othello M. Bourland, Van Buren, treasurer, and Dr. Dred R. Dorente, Fort Smith, secretary (reelected).

Medical Society Organized.—Montgomery County Medical Society was organized at Womble, March 22, with the following officers: President and delegate to the state society, Dr. Leroy S. Kennedy, Mount Ida; vice-president, Dr. John E. Alford, Womble; secretary, Dr. John H. McLean, Caddogan; corresponding secretary, Dr. John B. Stewart, Black Springs; and treasurer, Dr. Isaac N. Freeman, Washita.

CALIFORNIA

State Society Annual Meeting Planned.—The Medical Society of California will hold its annual meeting at Sacramento, April 19-21.

Decides Against Appellant.—The court of appeals, on March 16, is said to have affirmed the sentence of five years in the state prison imposed on Dr. Benjamin B. Lee, San *Francisco*, for manslaughter.

Plead for Benefactor.—Eight lepers of the colony at the San Francisco Isolation Hospital have joined in a petition to the San Francisco Board of Supervisors, asking that the board of health rescind its action in removing Dr. John Atcherly from attendance on them.

Antituberculosis Society Meeting.—At the first annual meeting of Alameda County Society for the Study and Prevention of Tuberculosis, March 25, Kenneth A. Millican was reelected president; Dr. Edward von Adelung, Oakland, first vice-president; Dr. Charles A. Dukes, Oakland, a member of the executive committee, and Drs. Nelson H. Chamberlain, Oakland, Edward N. Ewer, Oakland, Alexander S. Kelly, Oakland, Florence M. Sylvester, Oakland, F. M. Simpson, and Samuel J. Wells, Pleasanton, members of the board of directors; Dr. Ergo J. Majors, Oakland, chairman of the hospital committee; Dr. A. A. Alexander, Oakland, chairman of committee on public education and hygiene; Dr. Florence M. Sylvester, Oakland, chairman of the open air school committee; Dr. Walter S. Rutherford, Oakland, chairman of the membership committee; Dr. Edward N. Ewer, Oakland, chairman of public service committee, and Dr. Edward von Adelung, Oakland, chairman of clinic committee.

COLORADO

Site for Tuberculosis Sanatorium Bought.—By the purchase of fifteen acres near the southeastern limits of Denver, the Sisters of St. Francis have inaugurated a movement for the erection of a tuberculosis sanatorium to be known as St. Leo's Memorial Hospital, to cost $250,000.

Personal.—Dr. William S. Osborn, assistant superintendent of the Colorado State Insane Hospital, Pueblo, has been appointed chief of the Wisconsin State Receiving Hospital for the Insane, Mendota.——Dr. Jesse U. Sickenberger, Ouray, has been appointed surgeon of the Bureau of Pensions for the district of Ouray.

Faith Healers Convicted of Neglect.—In the Otero County Court, March 21, Judge E. W. McDaniel rendered his decision in the case of Mr. and Mrs. D. B. Messenger, La Junta, eddyists, charged with neglect in failing to call in a physician to attend three children after three other children had died. The decision holds the parents guilty of neglect.

Society Meetings.—The annual meeting of the Colorado Alumni Association of the Northwestern Medical School was held in Denver March 26. Dr. Alexander T. King, Pueblo, was elected president; Dr. Holmes, Pueblo, vice-president, and Dr. Karl F. Roehrig, Denver, secretary-treasurer. It was decided to hold the next annual meeting in Pueblo.——At the annual meeting of the Teller County Medical Society, held in Victor, March 29, the following officers were elected: Dr. John B. Polly, Victor, president; Drs. Albert C. McClanahan, Victor, and John A. Dunwody, Cripple Creek, vice-presidents; Dr. Thomas A. McIntyre, Cripple Creek, secretary-treasurer, and Dr. Albert C. McClanahan, delegate to the state medical society.

CONNECTICUT

Mental Hygienists Meet.—The board of directors of the Connecticut Society for Mental Hygiene, at its annual meeting in New Haven, elected the following physicians as officers: President, Dr. George Blumer, New Haven, and executive committee, Drs. Henry S. Noble, Middletown, Henry M. Pollock, Norwich, Whitefield N. Thompson, Hartford, and George H. Knight, Lakeville.

Malpractitioner Convicted.—Charles E. Harvey, Hartford, charged in the criminal superior court with performing a criminal operation, is said to have been found guilty and sentenced to imprisonment for not less than two nor more than three years in the state penitentiary, Wethersfield. It is stated that in 1905, on being found guilty of a similar offense, he was sentenced to one year in jail, expelled from the medical societies and his license to practice revoked.

GEORGIA

Personal.—Dr. William C. Lyle, Augusta, was recently elected secretary-treasurer of the Georgia Medical Association, and not Jarrett W. Palmer, Ailey, as was erroneously stated in THE JOURNAL of April 2.——Dr. Jesse G. McAfee has been appointed surgeon of the Southern Railway at Dalton, vice Dr. Charles P. Gordon, deceased.

District Society Meeting.—The Medical Society of the Ninth Congressional District held its annual meeting in Commerce, March 16. The plans of the Georgia State Tuberculosis Sanatorium, now being constructed at Alto, were presented by Dr. Jeff Davis, Toccoa, and a resolution was unanimously adopted that the state use its influence to have the general assembly apply the license tax on physicians of $10 per annum for the support of this institution. This will bring in about $25,000. The economic problem of tuberculosis and the fly as a carrier of infection were considered in papers presented by Dr. Lamartine G. Hardman, Commerce, who also gave a report of the Pellagra Conference. Dr. Jeff Davis, Toccoa, was elected president; Dr. Laetus Sanders, Commerce, vice-president, and Dr. A. D. White, Gainesville, secretary-treasurer.——The fifth semi-annual meeting of the Seventh District Medical Society of Georgia was held in Dalton, March 9, and the following officers were elected: Dr. Josephus J. P. Bowdoin, Adairsville, president; Dr. T. S. McLain, Calhouun, vice-president, and Dr. Harlan L. Erwin, secretary-treasurer (reelected), Dalton.

ILLINOIS

Sanatorium for Rock Island.—At the recent local election the municipal tuberculosis sanatorium tax levy was carried in Rock Island. This is the first city outside of Chicago to take advantage of the Glackin Sanatorium Tuberculosis Law.

Fire at Insane Hospital.—Fire [illegible] partially destroyed the store building of th[illegible] Hospital early in the morning of April 4. The 150 patients who were asleep on the third floor of the building were removed without casualty by the attendants.

Found Guilty of Murder.—After thirty-six hours' deliberation, the jury in the Sayler murder case at Watseka, on April 12, returned a verdict of guilty, sentencing Dr. W. H. Miller, Crescent City, to imprisonment for twelve years in the state penitentiary. Notice of appeal was filed.

Found Guilty.—Dr. Benjamin A. Arnold, Freeport, charged with committing a criminal assault while attending a young girl under 16 years of age, is said to have been found guilty, March 26, and sentenced to imprisonment for four years in the state penitentiary. A motion for a new trial was made.

New Interns for County Hospital.—As the results of the annual competitive examination, forty interns were selected for Cook County Hospital, each to serve for eighteen months. Of the successful candidates, 24 are graduates of Rush Medical College, and 8 each of Northwestern University Medical School and the College of Physicians and Surgeons.

Personal.—Dr. James A. Clyne, Joliet, who recently underwent an operation for appendicitis at St. Joseph's Hospital, is reported to be convalescent.——Dr. George P. Powell, Dixon, has been appointed a member of the local board of pension examining surgeons, vice Dr. David H. Law, deceased. ——Dr. Harry M. Hayes, Peoria, has returned from Europe.

Free Bed for Nurses.—A free bed for nurses afflicted with tuberculosis has recently been established at the Edward Sanatorium, Naperville, a department of the Chicago Tuberculosis Institute, in recognition of the valuable services of the nurses of Chicago, who as members of the Nurses' Auxiliary Committee of the Institute, took a leading part in the sale of Red-Cross Christmas stamps. From the proceeds of this sale, the money to support the bed has been appropriated.

Chicago

For a Contagious Hospital.—The Chicago Hospital Day Association has decided to set aside one-third of the money collected on Hospital Day, May 16, to a fund for the establishment of a contagious disease hospital, the need for which is urgent.

Personal.—Dr. Isadore S. Trostler was operated on in St. Joseph's Hospital, April 2, for a fracture of the right patella. ——Health Commissioner William A. Evans, Dr. William K. Murray and Dr. Egil T. Olsen have been appointed a board to pass on the medical and physical defects of 370 members of the police department who have attained the age of fifty years, and have been twenty years in the police service.

To and From Europe.—Dr. Julius H. Hess, accompanied by his family, sailed for Europe April 12. He will be abroad about four months and will inspect children's hospitals in Germany, Austria, France and England.——Dr. Charles Adams sailed for Europe April 9.——Dr. and Mrs. Franklin H. Martin have returned from Egypt and the Orient.——Dr. Frank W. Lynch has returned after a four months' trip abroad.——Dr. and Mrs. Jacob Frank have returned after a trip to Egypt, Palestine, Syria and Turkey.

KENTUCKY

Hospital Dedicated.—The new building of the Children's Free Hospital, Louisville, a model in every respect, was formally dedicated, April 2.

Appropriation Passed.—The governor has allowed the $30,000 annual appropriation for the State Board of Health to become a law without his signature, and he has signed the bill giving the King's Daughters Home for Incurables an appropriation of $10,000.

Hospital Commission Appointments.—The mayor of Louisville has appointed the following members of the Hospital Commission: Sam A. Culbertson, capitalist; Hon. Arthur Peter, former county judge; John H. Leathers, banker, and John Hubbuck, Sr., merchant. The recommendation of the Jefferson County Medical Society that a physician be appointed a member of the commission was not heeded.

Sanatorium to Open.—The Waverly Hills Sanatorium of the Louisville Board of Tuberculosis Hospital is almost completed and will be opened the latter part of this month. Two houses have been erected and the institution will accommodate at first from forty to fifty patients. Later it is hoped to double the capacity of the institution. Drs. George S. Coon, Sidney J. Meyers, and Eugene Y. Johnson are members of the board, and Dr. A. M. Forster will be in charge of the sanatorium.

MARYLAND

Merritt Guilty.—In the case of Dr. James B. Merritt, Easton, indicted in Caroline County Court for malpractice, the defendant is said to have pleaded guilty April 6, and to have been fined $1,000 and costs.

Legislative Action.—In spite of the efforts of Dr. Thomas A. Ashby the optometry bill was passed by the legislature; 13 counties and the city of Baltimore, however, are exempted from its provision. Other bills which received the governor's signature were the following: The bill regulating the practice of midwives; the bill regarding health and sanitation in Baltimore county; the pure food and drug law; and the lunacy bill for state care of the insane, which appropriated $600,000 for buildings and for the care of the colored insane, and for the supervision of asylums by the lunacy commission. The bill for reorganization of the State Board of Health was passed but has not yet been signed by the governor.

Baltimore

Personal.—A luncheon was given by Dr. Lewellys F. Barker at the Baltimore Club, April 1, to Drs. Louis Hamman and Paul Clough, who sailed for Europe the following day.——Dr. Herbert C. Evans, Baltimore, sailed for Europe March 23, to attend the International Congress of Anatomists to be held in Brussels.

The Trimble Lectureship.—The amount needed for the Trimble Lectureship is nearly completed and will be turned over to the Medical and Chirurgical Faculty of Maryland. Its purpose is to have a fund sufficient to yield an annual income of $1,000. The lectureship is in memory of Dr. Isaac Ridgeway Trimble, who died in Baltimore, Feb. 24, 1908.

MASSACHUSETTS

Personal.—Dr. Elmer E. Southard, Cambridge, has been appointed by President Gorgas, a member of the Council on Medical Education of the American Medical Association to fill the unexpired term of Dr. William T. Councilman.——Dr. W. Burton Thorning, Winchendon, accompanied by his wife and son, has started for Europe.——Dr. Charles W. Page, superintendent of the Danvers State Hospital, has resigned on account of illness in his family, and will be succeeded by Dr. H. W. Mitchell.——Dr. Joseph F. O'Shea has been appointed city physician of Lynn.——Dr. Emelie H. Jones Barker, resident physician at Wellesley for thirty-five years, and for more than twenty years superintendent of Eliot Cottage, has resigned.——Dr. S. B. Wolbach has been appointed assistant professor of bacteriology, and Dr. Walter R. Brinckerhoff, assistant and instructor in pathology from 1903-1906, and since that time connected with the national leprosy investigation at Molokai, H. I., has been appointed assistant professor of pathology in Harvard Medical School.

Hospital of Dentistry and Oral Hygiene.—A hospital of dentistry and oral hygiene has been opened at 31 Anderson street, Boston, under the charge of Dr. Alice M. Steeves.

Safe and Sane Fourth.—The Lawrence Medical Club has appointed Drs. George B. Sargent, John Parr, and Gustave E. Kurth, a committee to attempt to bring about "a safe and sane Fourth of July" in Lawrence and surrounding towns.

Bequests to Hospitals.—By the will of the late Lillie B. Hill, Malden, $1,000 is bequeathed to the Malden Hospital.——The will of the late Martha Rebecca Hunt, Somerville, leaves a bequest of $15,000 to the Baldwinville Cottage Hospital, one of $5,000 to the Charlestown School and Children's Hospital, one of $10,000 for the Massachusetts General Hospital, and one of $10,000 to the Willard Hospital, Bedford.

MISSOURI

Asks Release of Appropriation.—Three members of the board of managers of the State Sanatorium for Tuberculosis, Mount Vernon, appealed to Governor Hadley, March 23, to release $35,000 appropriated by the state legislature for the erection of a new building.

Medical Library.—The St. Joseph-Buchanan-Andrew County Medical Society is about to install a medical department in the public library. Arrangements have been made with the public library board whereby the society will provide 500 standard medical books and about 25 reliable medical periodicals to be circulated through the library.

Hospital Bills Signed.—The ordinance regulating the reorganization of the eleemosynary institutions of St. Louis was signed by the mayor, April 1, and went into effect April 10. The ordinance provides that instead of a superintendent in charge of each institution there shall be a hospital board composed of six citizens appointed by the mayor, who constitutes the seventh member of the board. The board shall contain not more than one physician from any one medical college. The board will appoint a commissioner, not a member of the board, who shall have supervision over the medical staff in charge of each institution. A chief physician with a staff of interns under him will be in charge of each institution. All the city dispensaries, the City Hospital, Female Hospital, Poorhouse, Quarantine Hospital and Industrial School come under the control of this board.

NEW JERSEY

Personal.—Dr. John J. Broderick has been appointed city physician of Jersey City, vice Dr. Henry H. Brinkerhoff, resigned to become director of the public schools medicine inspection department.——Dr. J. Franklin Chatten, Trenton, has returned from abroad.

Physicians Raise Fees.—In accordance with a decision made at a meeting three weeks ago, the Gloucester County Physicians' Protective Association raised their fees fifty per cent., beginning April 2. The high cost of living and the difficulty of collecting many accounts are given as the causes of the increase.

Preventorium Moves.—The Children's Tuberculosis Preventorium has been moved from the Cleveland Cottage, Lakewood, N. J., to Farmingdale, six miles north of Lakewood, where 100 acres of woodland and a free lease for twenty-five years of a 200-acre stock farm have been presented to the institution.

State Pediatric Society.—The New Jersey State Pediatric Society was organized in Hackensack, January 11, in connection with a symposium on "Infant Feeding" by the Bergen County Medical Society, when 13 physicians of the state met on the invitation of Dr. J. Finley Bell, Englewood, and after a statement by Dr. Henry L. Coit, Newark, effected organization. On February 3, at a meeting in Newark, permanent officers were elected.

Vivisection Bill Introduced.—At the request of Mr. Minard a bill has been introduced in the house, regulating vivisection, and providing that no person except a duly qualified physician or surgeon may perform vivisection; that it must be performed to advance knowledge which will save or prolong life, and alleviate human suffering; the operation must be performed under the direction of two members of the state commission; curare must not be used; no operation is to be begun until the animal is completely anesthetized, and the two commissioners shall, when desired, witness the operation.

NEW YORK

For Hempstead Hospital.—The Hempstead Hospital Association of Hempstead, L. I., has filed incorporation papers and will take over the South Shore Hospital.

Would Help Babies.—The Babies Dairy, organized to operate in New York City, and formed to supply proper food to orphans, pauper, destitute and sick children and to care for and board such children, and to educate mothers in the care and feeding of children, has been incorporated.

City Aid for Hospitals.—The legislature has been asked to authorize the city of Lockport to raise money for the purpose of improving, operating and maintaining the city hospital in that city and to issue bonds therefor.——A bill is before the legislature asking that the city of Mount Vernon be authorized to make an annual appropriation for the care and maintenance of the Mount Vernon Hospital.

Plans for County Tuberculosis Hospital Approved.—The proposed tuberculosis hospital for Monroe county will be on the cottage plan following the suggestion of Dr. Eugene H. Porter, state health commissioner, that three or four cottages be built on the site selected. An administration building will be also erected to contain the offices of the institution and apartments for the officers. The hospital is to be built on the county farm site in West Brighton.

Release of Insane Prisoners.—The Attorney General has advised C. V. Collins, State Superintendent of Prisons, that a patient at the Dannemora State Hospital for the Criminal Insane, whose term of imprisonment has expired, but who continues to be insane, is not entitled to be paroled. If the condition of the patient is such that it is reasonably safe for him to be at large and he has friends or relatives willing to maintain him he may be discharged by the medical superintendent of the hospital.

New York City

Museum of Safety.—With the assistance of the Public Health Section of the New York Academy of Medicine, it is hoped to raise $5,000,000 as an endowment for the Museum of Safety. Dr. William H. Tolman is director of the proposed institution.

Personal.—Dr. Sidney D. Wilgus, chairman of the Board of Alienists of the New York Commission in Lunacy, has been appointed superintendent of the Eligin, Ill., State Hospital, vice Dr. Vaclav H. Podstata, resigned, and will assume charge of the institution May 1.

Dentists for Hospital.—It has been announced that a dentist and an assistant dentist will be appointed to Mount Sinai Hospital for the purpose of caring for the teeth of patients in the wards. Special care will thus be secured for the teeth of patients suffering from affections of the mouth, throat or digestive tract.

Mott Memorial Library Goes to Academy of Medicine.—The Mott Memorial Library, which was founded by the late Louise D. Mott as a memorial to her husband, Dr. Valentine C. Mott, the surgeon, is to be sold in an action for partition brought by a granddaughter of Dr. Mott. The property was bought as a permanent home for the medical books, surgical instruments and anatomic plates left by Dr. Mott. The New York Academy of Medicine will take these articles and mark them.

Endowments.—Among the recent endowments to the New York Polyclinic Medical School and Hospital are one of $250,000 from Mr. William P. Clyde and one of $125,000 from Mrs. Helen Hartley Jenkins.——The will of Mrs. Amelia Kaufman bequeathes $1,000 each to Mount Sinai Hospital, the Hebrew Benevolent and Orphan Asylum, the Montefiore Home for Chronic Invalids, the Home for Aged and Infirm Hebrews, the United Hebrew Charities and Beth Israel Hospital.

Crusade Against Venders of Wood Alcohol.—The Department of Health has begun a campaign against sellers of wood alcohol. Inspectors have visited many saloons and taken samples of liquors offered for sale for analysis. Of the first fifteen samples analyzed three contained wood alcohol. This step has been incited by the number of cases of blindness due to wood alcohol that have come to the notice of physicians and by the records of the coroner's office, which show a number of deaths each year attributed to wood alcohol.

NORTH CAROLINA

Alleged Violators of Prohibition Law Acquitted.—Dr. Millard F. Fox, Guilford College, president of the Guilford County Medical Society, who was on trial at Greensboro for alleged violation of the state prohibition law, was promptly acquitted.——Dr. Louis N. Burleyson, Greensboro, tried by the same court on the charge of having issued sixty-six prescriptions for whiskey during January, was also promptly acquitted. During the last few months several such prosecutions have been made at different places in the state, and in each instance the accused physician has been promptly acquitted.

OHIO

Doctors' Building for Canton.—A three-story brick and stone office building, containing twelve suites of rooms, to be used exclusively by physicians and dentists, will be erected by Dr. Charles A. Crane.

New Tuberculosis Hospitals.—The counties of Auglaize, Allen, Mercer, Van Wert and Shelby will join in the building of a tuberculosis hospital at Lima to cost $75,000.——The bonds have been sold by the county commissioners for the erection of the Franklin County Tuberculosis Hospital. The structure will be three stories in height, and will be built on the grounds of the Franklin County Infirmary.

Illegal Practitioners Found Guilty.—Nora Cook, Columbus, charged with malpractice, is said to have been found guilty, March 30, and sentenced to imprisonment for two years in the state penitentiary.——Three out of five persons arrested in Toledo the last week in March by the State Medical Board, on the charge of practicing medicine without legal authority, pleaded guilty and were fined $25 and costs each.

Injunction Wiped Out.—The recent decision of the Supreme Court in the Rose case, upholding the right of the State Board of Medical Registration and Examination to revoke certificates, wipes out a number of injunctions restraining the board from acting in eight cases, in which certificates of physicians charged with improper conduct had been revoked. These cases will be considered by the board at the April meeting.

Did Not Report Births and Deaths.—Dr. Joseph J. Boone, Mount Victory, is said to have been found guilty of refusing to return certificates of births and deaths as required by statute, and to have been fined $5 and costs. In his defense, Dr. Boone said he had meant to comply with the law, but had been unable to secure the information within the ten days required. The fine was suspended for sixty days pending an appeal to the higher court.

Society Meetings.—The Physicians' Business Men's League of Dayton, at its annual meeting March 29, elected the following officers: President, Dr. Claude N. Christman; vice-presidents, Drs. Charles E. Shawen and Webster S. Smith; secretary-treasurer, C. C. McClain, and censor, Dr. William H. Swisher.——The Ohio Alumni Association of Jefferson Medical College met for organization at Dayton, March 15. Dr. Alonzo H. Dunham, Dayton, was elected temporary chairman, and Drs. Fred Fletcher, Columbus, and Richard S. Gauger, Dayton, secretaries. It was decided to hold the first regular convention of the society in Toledo May 4-6.

PENNSYLVANIA

Schuylkill County's Bulletin.—The most recent addition to the group of the county medical society papers, is the Bulletin of the Schuylkill County Medical Society.

Additions to the State South Mountain Sanitarium.—The Department of Health announced, April 8, that sealed proposals would be received by the Commissioner of Health until April 29, for the furnishing of all labor and materials necessary for the construction of the following buildings of the Pennsylvania State South Mountain Sanitarium, Mont Alto, in accordance with the plans on file at Harrisburg: 15 cottages; pavilion; alterations and additions to infirmary; nurses' and physicians' dining buildings at camp and infirmary; children's and additions to laundry and alterations n dining building.

Philadelphia
